If a naked floor board has had some liquid phosphorus spilt on it, although unlike the more spongy articles, it will not inflame to any great extent otherwise than superficially, yet it is equally liable to do so by heat or friction, to avoid which the boards mus t be first well wetted, and then planed as quickly as possible, throwing the shavings into the fire—keep wetting and planing as long as white fumes appear to be evolved. A floor-board may, however, be set on fire indirectly through the medium of the carpet on which the liquid had been sprinkled, spontaneously igniting. By way of showing what may be done with a naked floor board, I sprinkled some liquid phosphorus on a small deal board ¼in. thick, placed on a stout sheet of iron, with a thermometer at 56deg. standing by its side, and in ten minutes the surface of the board burnt with considerable activity. Again, I took another board, sprinkled some phosphorus over it, and when dry, gently drew across it a pointed iron instrument, and the friction was quite sufficient to set it on fire, so that it cannot be denied that there is great danger attending the use of this liquid.

Some persons have recommended the use of wet sand to stay or prevent the absorption of the liquid, but that does not appear to be of much value, as by its density, it still finds its way to the board, which, unless kept constantly wetted, is liable to be fired by the slightest heat or friction of any kind. If a fire has been actually produced the best thing to extinguish it before it goes far, is to have ready a solution of carbonate of ammonia (common smelling salts), say 1lb. of the salt to seven pints of water, adding one pint of the crude ammoniacal liquid of the gas works, and keep projecting it on to the flaming body till it is put out. This appears to be all the consolation and advice I can at present offer, but I propose continuing my experiments and investigations upon this infernal liquid, as the present excited state of society, and the country generally, demand that something should be done to counteract, if possible, the mischief being perpetrated by those misguided and cruel wretches calling themselves Fenians, who will assuredly find that this stuff is not quite so easy to manage, nor so harmless to themselves as they imagine, as the following recent incident clearly shows. A few more such occurrences will probably cause it to be laid aside altogether, and the sooner the better, for there is no question as to its danger.

"Greek fire" appears to be a dangerous weapon to carry. Two men were going along a street in Cork lately, when the explosion of a bottle in the pocket of one of them made him throw off his coat instanter. The man and his companion then made off. On a bystander lifting the coat, another bottle exploded, and before the police came up, the garment, and what seemed to be a number of documents in it, were partly destroyed.

Correspondence.

SUGGESTIONS ON THE DEFENCE OF FORTRESSES.

No. IV.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—A thorough knowledge of the configuration of the surface of the ground surrounding a fortress—and even of the composition, geological nature, and structure of such ground—is indispensable for a successful defence, because such a knowledge would be one of the many points which, if taken advantage of to their utmost extent, would invariably be in favour of the defence. On the land environs of a fortified harbour, the same, or very similar, measures for the defence will have to be taken as are necessary for the defence of an inland fortress; one of these measures would consist in artificial changes of the natural surface configuration of the surrounding ground, in such a manner as to insure additional advantages to the defenders. Eminences which could not conveniently, and with the certainty of a successful defence, be covered with works, had better be removed altogether, and in the case of many British harbours, the material thus removed could most advantageously be applied to various harbour improvements. Hollows or indentations of the ground likely to afford cover to the enemy should be filled up, and so forth. The attack by means of trenches, parallels, &c., dug out of the natural ground, is generally admitted to be the easiest and cheapest to the besieging enemy; and it follows, hence, that it ought to be one of the chief objects on the part of the defenders to take such measures as would render that mode of attack exceedingly difficult, if not altogether impossible. One of these measures would simply consist in removing, for a considerable distance around the fortress, and to a depth of, say, twelve or more feet, all the natural ground which is of a tough cohesive nature, and in replacing said ground by a correspondingly thick layer of loose stones, pebbles, and shingle. It is not difficult to imagine how an enemy would fare while attempting to open his trenches under our fire in such artificial ground. On such portions on the land side of our fortress where the taking away of such a depth of ground would enable us to set such ground under water at high tides, by means of sluices, the placing such an artificial layer of pebbles, &c., may be dispensed with; although it cannot be denied that by even then covering the ground to a certain depth with a layer of loose pebbles, we would render far more difficult the enemy's task of opposing our inundation by means of counter dykes, &c.

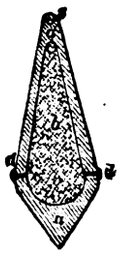
In an engagement between the Prussians and Austrians, during the Seven Year's War, a large body of troops were compelled to abandon an otherwise very strong position, by the enemy firing solid shot from what at that time was considered an almost harmless distance—simply because the destructive effect of each solid shot thus fired was very considerably increased by the circumstance of the ground being covered with a number of heaps of loose pebbles, which, during many years, had been gathered by the peasants from their adjoining fields, and carted to that spot—and each shot, on striking any of those heaps, scattered a load of pebbles all around, thus acting, in fact, like grape and canister would at a shorter range. About twenty years ago the writer of these suggestions had occasion to be behind a temporary entrenchment, part of the parapet of which happened to be built of large but loose stones, which, though affording ample protection against the hostile small-arm bullets, were scattered about in a most destructive shower on being hit by a six-pounder solid shot. By now purposely placing here and there heaps of loose stones and pebbles, we would increase the effect of our shot at very long range, care being taken that by previously fixed aim lines of mathematical precision our gunners be enabled to point their guns, even during the darkest night, so as to hit such heaps. I may here parenthetically remark that a table of aim lines, carefully drawn up from previous practice, should be in the hands of the gunner of every piece of ordnance in the fortress, so that by adjusting the gun at the angle indicated by the respective column in the table of aim lines, any given point within range could be hit without being seen. In the case of a fortified harbour, a thorough knowledge of the surrounding ground should also embrace the adjoining sea; and a relief map or model correctly representing the configuration and composition of the bottom of the sea for a considerable radius around a harbour, with contour lines showing the various levels of the sea surface at the various tides, with arrow-headed or vane-headed pins stuck into the proper spots on the model to show the direction of currents, with, say, movable wire or thread, arrangements to indicate the range at various elevations of each of the principal guns, should be prepared, and should be accessible to all those officers and others engaged in the defence, who might require the assistance of such a map. Obviously, such model maps ought not to be accessible to the general public, simply because a knowledge thus laboriously acquired ought to be the sole property of the defenders, and the publishing of any such information would indeed be equivalent to pasting on the outside of a burglar-proof safe a detail description of the construction of the lock.

In the defence of harbour and coasts, submarine engineering will yet play a far more important part than it did hitherto; and the suggestion of the formation of special local corps of "submarine engineers" and "divers" would hence appear quite natural. It would indeed appear very desirable that the bulk of the men composing such a corps ought not to be liable to be drafted into service elsewhere, because their efficiency would naturally depend upon the fact of their being most thoroughly acquainted and familiar with the sub-aqueous environs of the seaport where they may be stationed. The formation of such a branch of the service would probably result in the individual members of the same discovering, by their minds being constantly turned in that direction, various improvements for enabling men to carry on submarine operations with greater ease than they ever could hitherto. The services of our corps of "submarine engineers" could be made to assist in the defence of our harbours in a variety of ways. Occasions may arise where an enterprising enemy's ships or floating batteries may come so very close to our own defending floating or stationary works, that the attempt of blowing up the enemy's ships by means of torpedoes might be dangerous to the defenders themselves. But even then the enemy's vessels may be destroyed by the discharge of huge mortar-like submarine guns, so placed that all the force of their explosive charge would be expended only in the direction of the attacking enemy's ships. Obviously, for the construction and working of such submarine batteries we should have to rely on our corps of submarine engineers. Submarine permanent roads may be laid down for the conveyance of huge masses of explosive substance, destined for the destruction of the enemy's ships.

It would be but natural that the thoughts of the individuals, of which our corps of submarine engineers is composed, would be concentrated upon that special branch of the service, and that thus new and improved methods would be devised for enabling human beings to walk about and work at the bottom of the sea with greater ease and efficiency than has been possible hitherto. Some remarks on submarine "chevaux de frise" and temporary "artificial breakers" I shall defer to a future letter, as I could hardly convey my meaning of those novel arrangements clearly without the assistance of diagrams. Balloons might be advantageously employed by the defenders, not only for the purpose of observing the enemy's movements from a great

Digitized by Google

height, but also, if the state of the weather be favourable, for attacking the enemy's fleet, by dropping shells upon his ships from a great height. The accompanying diagram gives the section of such a



shell, exclusively constructed for that purpose. *a a* is the section of the body of the shell, with the loop *c*, by means of which it is attached to the car of the balloon; *b* is the explosive charge, and *d d* the percussion arrangement for exploding the shell as soon as it strikes the object. A shell of such a shape being dropped from a very great height, would strike a ship with tremendous power and do very great damage. As regards aeronautics in general, I feel convinced that they may play a not unimportant part in warfare; but I may here, *en passant*, remark, that all attempts to raise a body in the air, and keep it suspended therein by means of fans or screws, must invariably result in failure; and that all mechanical contrivances and their motive power ought to be exclusively directed to the steering and propulsion through the air of the balloon—the car or cars being kept sustained in the air by means of an inflated balloon or several balloons. Who would ever think of attempting to keep a ship afloat in the water by means of revolving fans or screws?—I am, Sir, yours, &c.,

February 19. G. J. GÜNTHER.

SQUARING THE CIRCLE.

SIR,—Knowing well the Astral physical generalizations, affirmed in what are called Kepler's planetary laws, which have properly made his name so famous, and taking a deep interest in astronomy, I wish to ask from your correspondent "Commander, R.N.," who, in your issue of to-day, justly corrects my use of the word "Magazine" for "Almanack," what he exactly means by the last paragraph of his letter, viz.:—"In the computations of which the value of trigonometrical lines are based upon the long accepted ratio of the circle to its diameter."—I am, Sir, yours, &c.,

WILLIAM HARVEY.

London, February 14.

SIR,—I am afraid, from Mr. Nicholson's remarks, that in my desire to spare your space I may have been a little obscure in my last letter. When I stated that Mr. Nicholson's proposition was not new, I had in my eye the rule for finding the area of a circle by multiplying half the circumference by the radius, with which his demonstration coincides. As to "squaring" the circle, of course his parallelogram can only be approximately squared by exactly the same infinite series of decimals as is the circle now, unless indeed he propounds a different ratio for the circle from that generally accepted at present. The rule I have referred to may be found in Keith's "Practical Geometry." I think with Mr. Nicholson it would be a very narrow and illiberal idea that none but professors should be allowed to write in periodicals on scientific subjects.—I am, Sir, yours, &c.,

THOMAS SCUTT.

February 15.

SIR,—Mr. Harvey, in replying to my letter, states that he does not allow the correctness of trigonometrical tables, but he does not say anything at all against the manner in which I find by construction, and by employing only the (even by Mr. Harvey acknowledged) rule for the area of a triangle, that his rule gives the area of a circle of 1' diameter about 1,2 square inches larger than the area of the circumscribed polygon of twenty sides. If Mr. Harvey has made the drawing and calculation, as explained in my last letter, he must have found out his mistake, and must know that the statements in his last letter are not true. If he did not make the drawing, he acted on the principle "Where ignorance is bliss, 'tis folly to be wise;" and even after being proved wrong, he can then fancy that at some future period, when technical education is more appreciated, every schoolboy will know the name "Harvey" as well as "Pythagoras," and will be thankful to him for simplifying 3,1415926 into 3,2.

I have also read some letters of Mr. Nicholson, and if I translate his last letter into figures, I find his value of $\pi = 3{,}14053$. The correct $\pi = 3{,}14159$, and Mr. Nicholson's value is too small by 0,00106 or about 1-30th per cent., which is very good indeed. But even if Mr. Nicholson should find a real construction for a square nearly equal in area to a given circle, it will be of no use whatever, because all those who want areas of circles can find them very quickly in their tables; but if they use Mr. Nicholson's construction, they will finally find the side of a square, and will have to look in their tables for the area of that square, so that the time spent with the construction is lost, and the result is after all too small by about 1-30th per cent.—I am, Sir, yours, &c.,

A. W.

February 17.

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith.—ED. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

RECEIVED.—C. B.—G. W. H.—J. B. T.—F. P.—H. E. R.—J. B.—T. G.—Messrs. C. M. and Co.—W. R.—B. M'L.—W. T. F.—W. M.—R. S.—T. H.—R. I.—H. K.—T. S.—M. B.—A. W.—G. E. P.—G. W. H.—L. O.—G. J. G.—G. R.—R. G. S.—F. H.—T. W. F.—H. R.—Messrs. W. T. H. and Co.—W. M'D.—J. S.

Meetings for the Week.

MON.—Royal Geographical Society.—C. R. Markham Esq., on "The Geographical Results of the Abyssinian Expedition to January 22, 1868," at 8.30 p.m.

TUES. — The Institution of Civil Engineers. — 1st, renewed discussion on "The Supporting Power of Piles, &c.;" and, 2nd, Mr. C. P. Sandberg, A.I.C.E., on "The Manufacture and Wear of Rails," at 8 p.m.

Royal Institution.—Professor Tyndall on "The Discoveries of Faraday," at 3 p.m.

WED.—Society of Arts.—Wentworth Lascelles Scott, Esq., on "The Supply of Animal Food to Britain, and the Means Proposed for Increasing it," at 8 p.m.

THURS.—Royal Institution.—Professor Tyndall on "The Discoveries of Faraday," at 3 p.m.

FRI.—Royal Institution.—A. Vernon Harcourt, Esq., on "Chemical Actions," at 8 p.m.

SAT.—Royal Institution.—Professor Roscoe on "The Non-Metallic Elements," at 3 p.m.

Naval, Military, and Gunnery Items.

THE "Brenta," of Bassano, a city of what was formerly Austrian Italy states that a bomb exploded in the cathedral there during the celebration of the *triduum* for the victory of Mentana, but that fortunately it caused no injury.

The 64-pounder Palliser rifle gun has completed its test at the Woolwich butt of the 2,000 rounds ordered by the War Department, and has undergone the usual searching and examination, without the appearance of any blemish or signs of weakness.

SIR W. G. ARMSTRONG has been made a Knight Commander of the Order of San Maurizio e Lazzaro by his Majesty the King of Italy, in recognition of his services as an artillerist, and as the consequence of the definitive adoption of his ordnance for the Italian naval service.

We, "United Service Gazette," are given to understand that H.M.S. "Wyvern" is at present armed with "three guns and a half," the explanation of this circumstance being that in experimenting with 150lb. shot the breech of one of the muzzle-loading 300-pounders was blown completely off. An order has been given that the "Wyvern" is not to fire her guns for the present.

THE Bureau Veritas of Paris has published a statement of the marine disasters which occurred during the past year. The total number of vessels lost in 1867 is 3,045, an increase of 113 as compared with 1866. Of these losses nearly one-half have fallen upon England, whose contribution to the unfortunate list has been 1,438 vessels, while the United States has lost 364, France 273, Prussia 156, Norway 116, Holland 112. Of steamers lost the number was 145, and of sailing vessels 2,900.

THE lighthouses on the coasts of Italy have of late received the special attention of the Government. The sum of 1,750,000f. (£70,000) has been expended in the construction of new lighthouses. Previous to the year 1860 the Italian lighthouses, not including those belonging to the Venetian and Roman States, were fifty-eight in number. Since then thirty have been constructed, and eight are now building.

THE "Melbourne Argus" states that an attemp is to be made to open up a direct trade from Melbourne to Japan. The barque "St. Bernard," which cleared out on the 21th of December, chartered and loaded by Mr. Tallerman, a well-known Melbourne importer, was the first vessel to leave Hobson's Bay for a Japanese port. More than half the cargo consists of colonial produce, among which are about 100 tons of beef and mutton preserved in various ways, colonial beef and mutton hams, bottled fruits, leather, flour, hay, oats, horses, cows, sheep, and furniture. Among the imported articles shipped for this new markt were wines and spirits, clothing, and fire-arms.

ASEL ECTED armour plate from a number made at the rolling-mills of John Brown and Co. for the turret-ship "Monarch," was tested on Monday on board the "Thunderer" target-ship at Portsmouth, under the superintendence of Captain A. Hood, C.B., commanding the gunnery establishment of H.M.S. "Excellent." The plate weighed 6 tons, was 12ft. in length by 3ft. 6in. in breadth, and 8in. in thickness. Nine shots were fired at the plate, all striking in a space measuring 35in. by 18in., and seven of the shots in a central space 18in. square. The plate proved to be of unusual excellence, and will receive a high classification. Messrs. J. Ellis and J. C. Bayley were present as representing the manufacturers.

A RECENT Admiralty order directs preparations to be made at Chatham for the construction of another powerful armour-clad war ship of the "Hercules" class, in the large dock from which the "Hercules" was recently floated out. The instructions accompanying the order state that the new vessel will be in all respects the same as the "Hercules" below the water-line, and that the ironwork for the keel of the new ship is to be immediately commenced.

IT has been a common expression in the mouths of Englishmen that "boards" have no soul; but, to prove that the Admiralty Board has some sense of feeling, we, "Army and Navy Gazette," can say that only lately a commander in the Royal Navy, who had met with a fearful accident, had his case properly represented and, to the gratification of himself and friends, a decision was rapidly arrived at by their lordships doubling the pension, which, under ordinary circumstances, he would have received. Again, a poor assistant-surgeon died who had not served sufficiently long to qualify his widow for a pension—in fact, she was in deep distress. My lords lost no time in directing a handsome gratuity to be sent to her, following up the principle of "*bis dat qui cito dat.*"

IN consequence of the new army organization in Southern Germany, Baden, with her 1,400,000 souls will possess an army of 18 battalions of infantry, 15 squadrons of cavalry, ten field batteries, and the usual auxiliary branches in due proportion. This force will number in peace, 14,828. In war it will be raised to 24,000 inclusive of non-combatants, but exclusive of 8,900 depot troops, to fill up losses. In addition to this there is a reserve force of 8,000 Landwehr; the whole forming a total of 936 officers, 38,547 rank and file, 4,194 non-combatants, with 7,517 horses.

THE following appointments have been made at the Admiralty:—Lieut. Robert H. Harris, to the "Britannia;" Edwin Boulton, chief engineer, to the "Lion;" William H. Rundle, chief engineer, to the "Indus," for the "Princess Royal;" Thomas F. Hall, chief engineer, to the "Fisgard," for the "Wolverene;" Sub-Lieut. William B. Rennell to the "Beacon;" Frederick Maitland, midshipman, to the "Achilles;" A. Irwin, surgeon, to the "Bristol;" Samuel M'Bean, assistant-surgeon, additional, to the "Wellesley;" and Samuel E. Lark, assistant-paymaster, additional, to the "Mersey."

The following are the items of the extraordinary estimates of the War Department and of the Navy of Austria for the present year:—1. Extraordinary expenses once for all.—(*a*) Armament of the troops with breechloaders and complement of deficiencies in ammunition and material of artillery, £2,170,000. (*b*) Complement in uniform and accoutrements, £270,000. (*c*) New organization of army train and deficiencies in harnessings, £68,500. (*d*) Extraordinary requirements of remounts for the newly-organized artillery, £12,600. (*e*) Ambulances, £7,500. (*f*) New fortifications and barracks, £180,000. In all, £2,708,600. 2. Transitory extraordinary expenses.—Pay of supernumeraries for the campaign of 1866. £360,000. In all, £3,068,600. For the Navy, once for all, 1st, stores and expenses of the arsenal, £27,000; 2nd, land and sea fortifications at Pola, £73,000; together £100,000.

Miscellanea.

THE number of visitors at the Patent Office, South Kensington, for the week ending February 15, was 3,656; total number since the opening of the Museum, free daily (May 12, 1858), 1,246,788.

THE value of the silver ore imported into the United Kingdom during the 12 years ending 1866, was as follows:—1855, £564,580; 1856, £354,970; 1857, £299,511; 1858, £209,154; 1859, £342,637 1860, £382,806; 1861, £289,373; 1862, £331,564

Digitized by Google

1863, £272,826; 1864, £251,568; 1865, £382,391; and 1866, £275,599. These imports are thus making little or no progress.

THE visitors to the South Kensington Museum, during the week ending February 16, 1868, were—On Monday, Tuesday and Saturday, free from 10 a.m. to 10 p.m., 10,003. On Wednesday, Thursday, and Friday (admission 6d.), from 10 a.m. to 4 p.m., 1,496—Total, 11,499. Average of corresponding week in former years, 10,016. Total from the opening of the Museum, 7,197,749.

THE thermometer at the Melbourne Observatory reached 104deg. in the shade on December 19. An instance of the extreme variability of temperature in the climate is afforded by the fact that at Grant, on the Crooked River, on the 10th, the heat was very great, the glass standing at 88deg. in the shade—an altitude uncommon in that alpine locality. On the 12th—only two days afterwards—the temperature was at freezing point, and snow was lying six inches deep on the plains.

A FIRE broke out on Saturday in the port of Antwerp, which was extinguished during the evening. Two vessels containing 208 barrels of petroleum were consumed by the flames. The amount of the property destroyed is estimated at 150,000f. The whole of the loss is said to be insured, partly in Belgian and partly in Dutch insurance companies.

We read that an *employe* on the Orleans Railway has invented an amalgamation of coal and other combustible materials, especially petroleum, made for convenience of use in the form of bricks, which, it is said, is calculated to effect an immense saving in the fuel necessary for generating steam. It burns with intense heat, and for a long time, and is likely to be extensively employed very shortly on the Orleans line, where some very satisfactory experiments have been made with this material. The compound is called *briquettes bordelaises*.

THE last relics of the old Fleet Prison are fast disappearing. The other day the materials of several houses and other premises at the corner of Ludgate-hill and Farringdon-street, including the boundary wall of the old Fleet Prison, were disposed of by auction, in order to carry out the long-contemplated improvements in that locality, and in a few days not a vestige will remain of that celebrated place of incarceration for unfortunate debtors. The prison was burnt in the great fire of 1666; built anew, and again destroyed in the riots of 1880; rebuilt, and finally pulled down in April, 1844, when the site was purchased by the Corporation of the City of London for £29,000.

THE Academy of Agriculture, Commerce, and Arts, of Verona, intend celebrating, in the course of the present year, the one hundredth anniversary of their establishment, by an agricultural and industrial exhibition, with a show of cattle, to be held at Verona from the 14th of September to the 15th of October. For this purpose, the Minister of Agriculture has granted a subsidy of 4,000f. and sixteen medals; the Provincial Council, 4,000f.; the Chamber of Commerce, 1,000f.; and the Municipality of Verona, 3,000f.

A SINGULAR and fatal accident lately formed the subject of inquiry at Liverpool. An old man troubled with rheumatism, had obtained a colourless liniment, which on Sunday last he gave to his wife and asked her to rub it upon one of his hips. She poured some of the liquid upon her hand, and after rubbing her husband for some time, in order to increase its efficacy, she warmed her hands at the fire. The liquid on her hands became ignited, and she was very severely burned. Her husband approached to render her assistance, and the liquid upon his hip became ignited also, his clothes were burned, and he sustained such serious injuries that he soon afterwards died.

WE have to record the death of Mr. William Herapath, the well-known toxicologist, of Bristol. The deceased gentleman, who was seventy-two years of age, had only been ill for a short time, and expired on the evening of yesterday week at his residence in the Old Park, Bristol. Mr. Herapath was the son of a maltster, and for some little time followed the occupation of his father. He had, however, a strong inclination for scientific pursuits, and he devoted himself to the study of chemistry. Nearly forty years ago he gained a reputation by his analysis in a case in which a woman named Burdock was convicted at Bristol upon circumstantial evidence of poisoning. In the more celebrated case of Palmer, of Rugeley, Mr. Herapath was a witness, and he had also been concerned in many other important criminal and civil trials.

A CONSIDERABLE portion of the ruin at Wemyss, known as Macduff's Castle, recently fell down, probably owing to its having been weakened by the late severe storms. The castle is extremely old, an age of 1,000 years at least being attributed to it. Centuries of exposure to the weather have honeycombed some parts of the masonry to the depth of 8in. It was the north-eastern portion of the ruin which fell the other day, the western part still standing. Underneath the western building is a large cave, in which there is a well, and it is supposed that there had been a subterranean passage from the case to the castle in former times.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgement:—

BOILERS AND FURNACES—2009, 2042, 2043, 2048, 2049, 2050 2075, 2086, 2099

BUILDINGS AND BUILDING MATERIALS—2028, 2039, 2041

CHEMISTRY AND PHOTOGRAPHY—2006, 2011, 2012, 2055, 2100

CULTIVATION OF THE SOIL, including agricultural implements and machines—2023, 2060, 2071, 2088

ELECTRICAL APPARATUS—2015, 2016

FIBROUS FABRICS, including machinery for treating fibre, pulp, paper, &c.—2013, 2014, 2017, 2020, 2058, 2068, 2076, 2085, 2087, 2096

FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—2034, 2051, 2079

FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c.—2032, 2035, 2056

GENERAL MACHINERY—2010, 2022, 2025, 2027, 2029, 2030, 2037, 2044, 2047, 2053, 2054, 2063, 2073

LIGHTING, HEATING, AND VENTILATING—2045, 2065, 2078

METALS, including apparatus for their manufacture—2046, 2092

MISCELLANEOUS—2007, 2019, 2021, 2024, 2031, 2033, 2062, 2064, 2067, 2069, 2070, 2072, 2074, 2081, 2082, 2083, 2084, 2090, 2093, 2094, 2095

ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—2018, 2026, 2038, 2061, 2080, 2089

SHIPS AND BOATS, including their fittings—2052, 2057, 2059, 2066

STEAM ENGINES—2036, 2077, 2097, 2101

WARFARE—2040, 2091, 2098

2009 J. CREDLAND. *Improvements in the arrangement of the flues of certain boilers for generating steam.* Dated July 9, 1867.

The object of this invention is the saving of fuel by a better application of the heat arising from its combustion, and the improvements are applicable to boilers with one or more internal flues, and where the products of combustion, after passing through the internal flues, are then circulated round the exterior of the boiler by flues formed in brickwork, and the invention consists in contracting the flue so that its area is much less than that of the ordinary flue, and in making the line or face of the brickwork of the flue to come parallel to the external surface of the boiler, or nearly so, and at an average distance of about 3in. therefrom, the upper part of the flues terminating a little below the water line of the boiler. The lower part of the boiler rests upon a wall passing the lengthway of the boiler, and upon each side of this wall the flues descend to make a recess or receptacle for dust and soot. The products of combustion pass through the internal flues of the boiler, then return towards the front of the boiler along one external flue at ore side, and then back towards the chimney along the external flue upon the other side of the boiler.—Patent abandoned.

2010 E. and F. CROOK. *A new or improved machine for crushing bones and other materials.* Dated July 9, 1867.

Here the inventors employ rollers, by preference two, mounted on shafts opposite to and parallel with one another. The circumferences of these rollers are fitted with concave teeth, the number of which may be varied. These teeth, which are sharpened, somewhat overlap and work between each other, the distance being regulated according to the size to which it is required to reduce the bones or other material. Motion is communicated from a flywheel on a shaft extending across the machine, and carrying at its other end a pinion in gear with a wheel on one of the roller shafts, the other end of which carries a toothed wheel which is itself in gear with a wheel of a similar size on the other roller shaft. The material to be crushed is placed in a hopper, passes between the teeth of the rollers, and falls into a receptacle underneath provided for the same.—Patent abandoned.

2011 W. E. NEWTON. *Improvements in the rectification and purification of alcohol.* (A communication.) Dated July 9, 1867.

This invention consists, first, in the employment of water in admixture and in contact with the alcoholic vapours of the column, as an active purifier of the odorous products to be eliminated. Second, in the employment also of water as the vehicle of all chemical agents for fixing the extraneous products to be eliminated, by applying these agents in direct contact with the alcoholic vapours in the interior of the column. Third, in the substitution for the ordinary analysers of the analyser and concentrator described acting simultaneously by its surfaces of condensation, and by filtration or separation, of the vapours and liquids.—Patent completed.

2012 R. SMITH. *Mixing water, iron, sulphur, arsenic, and oils together, making a perfect coating for iron or wooden ships, yachts, and steamboats.* Dated July 9, 1867.

Here the inventor takes 1lb. of crude brimstone, and a quarter of a pound of steel or iron filings; the filings are to be in a state of rust; he pounds them together with a little water, and afterwards adds 1 pint of water, mixes all together, adds 1 part of linseed oil, and stirs until he produces a mixture fit for use. Arsenic may be added in the proportion of about 3oz. to the above, and the same quantity of filings must be added. If fish oil be used, a double portion of filings is needed to cause the mixture to dry.—Patent abandoned.

2013 W. R. LAKE. *Improvements in machinery for manufacturing cards for combing or carding fibrous materials.* (A communication.) Dated July 9, 1867.

This invention is not described apart from the drawings. —Patent completed.

2014 W. WOOD. *Improvements in the manufacture of Turkey, Wilton, and Brussels tapestry, and other terry and cut-pile carpets and rugs.* Dated July 9, 1867.

These improvements consist in forming the piled surface of these fabrics of yarns made wholly or partly from undyed natural coloured wool, hair, or other animal fibres, adding thereto, to produce a required shade of colour, a portion of dyed wool or fibres. The improvements relate, second, to the binding warp of the above-named fabrics, and consists in discarding one half of the ordinary binding warp threads, and in using but one thread in each space of the reed, and making this half warp bind both the upper and lower weft shoots alternately, the dead worsted or "dead warp" lying between the said weft shoots. The improvements relate, third, to the dead warp in tapestry and other terry and cut pile carpets and rugs, and consist in twisting together the separate threads ordinarily employed so as to form but one compound thread in each space of the reed, whether the separate threads be made from the ordinary linen or cotton, or from wool, silk, or jute; and in making, when a stronger or smoother compound thread is desired, the twist of the doubling in the same direction as the twist of the spinning.—Patent abandoned.

2015 W. S. ANDREWS. *Improvements in means or apparatus used in effecting telegraphic communications.* Dated July 9, 1867.

The object of this invention is to enable instruments, such as those now known as Hughes' type printing instruments (and also other instruments), to work long distances for land or submarine purposes in various weathers, by providing a relay or relays at one or more points between two termini to reinforce or renew the electric current.—Patent completed.

2016 W. S. ANDREWS. *Improvements in means or apparatus used in effecting telegraphic communications.* Dated July 9, 1867.

The patentee claims arranging or combining means or apparatus used in effecting telegraphic communications whereby instruments of the character of those called "Morse" ink writing instruments are adapted to make indications by short currents of equal duration, and of opposite polarity, on one wire, substantially as described. Also arranging apparatus used in effecting telegraphic communication so as to obtain relays between distant parts when communicating to long distances, in manner substantially as described. He also claims the mode described of arranging insulating supports for suspending conductors used in effecting telegraphic communications.—Patent completed.

2017 H. ENGLISH and J. FARNDON. *Improvements in apparatus for operating the shuttles of looms for weaving narrow fabrics.* Dated July 9, 1867.

According to one portion of this invention the parts taking immediate effect on the shuttles in the operation of driving are comprised entirely within the limits of the length of the race, and consist of levers mounted on axes having spur or other gearing taking into a rack bar below, by which the motion is communicated. Another part of the invention relates to means of driving the shuttles by the oscillating motion of the batten, which, as usual, is suspended from above.—Patent abandoned.

2018 J. E. WHITING. *Improvements in suspension bridges and other structures in which girders are employed.* Dated July 10, 1867.

This invention consists in connecting by a hinge, or other flexible joints, the ends of the upper chords of two diagonally braced girders, so that each girder may have its top chord always in tension; and these girders are constructed so that this may be the case, and they are inclined to one another at an angle properly chosen, according to the proportions of the structure, and the requirements of the case, as to moving and fixed loads, and so as, the girders being free, to adapt themselves to changes of length consequent on changes of temperature and strain. —Patent completed.

2019 J. S. HOOD. *Improvements in life buoys.* Dated July 10, 1867.

The object here is to render the buoy self-inflating, which may be effected by a stop-cock, the opening of which admits air into the buoy for inflating the same, and allows the air to escape when the buoy is out of use.—Patent completed.

2020 D. and J. COLLINGE. *Improvements in looms for weaving sponge cloths by power.* Dated July 10, 1867.

This invention is not described apart from the drawings. —Patent completed.

2021 H. B. FOX and J. T. HALL. *An improved stopper for bottles, jars, casks, and other vessels.* Dated July 10, 1867.

The patentees make these stoppers of a combination of wood and an elastic material, such as cork or india-rubber. The central part of each stopper is made of wood, and the periphery of a ring or piece of cork, or other flexible material.—Patent completed.

2022 F. HOLMES. *Improvements in pumps.* Dated July 10, 1867.

By this invention a treble action is obtained from a single-acting pump with two pistons on the same rod. From about the middle of a pump barrel having a double piston, or two pistons, the upper of which is a bucket piston, on the same rod, a pipe is carried down which terminates at its lower end in the liquid to be raised; a pipe leads from the upper part of the barrel to deliver the liquid raised by the first pipe. From the bottom of the pump barrel a pipe is carried down, which also terminates at its lower end in a closed chamber immersed in the liquid with which it is filled. The chamber is provided with inlet valves, and a pipe is carried up from its lower part to deliver the liquid. The patentee prefers to employ two pump barrels, and two sets of pumps, the two pumps acting alternately.—Patent completed.

2023 J. N. PAXMAN and H. M. DAVEY. *Improvements in drying wheat and other grain, and pulse and seeds, and in the apparatus employed therein.* Dated July 10, 1867.

This invention consists in the use of a cylinder within which may be placed one or more cylinders heated by steam, and through which the wheat, &c., to be dried are caused to pass, such substances being kept in agitation whilst a current of air is made to pass through the cylinders, and so disperse or dispel the moisture from the wheat, &c., under treatment.—Patent completed.

2024 G. DAVIES. *An improved metallic eye for laces.* (A communication.) Dated July 10, 1867.

Here the patentee first takes a thin plate of metal, and by punches and dies cuts from the plate pieces consisting

Digitized by Google

of two flat rings connected by a strip. He then, by dies, forms on one ring a projecting annular flange, thereby reducing it to the form of an ordinary eyelet. Another operation is to turn up the edges of the intermediate strip, so that it may be rounded underneath. He now bends the strip so as to form an eye or loop, causing the eyelet to pass through the other ring, after which the device is ready for attachment. A hole is formed in the fabric, and the eyelet portion of the device passed through the hole, after which an ordinary eyelet is inserted into the interior thereof, when the whole is removed to an eyelet machine and riveted, so that the device consists of a ring or loop standing out at right angles from the material, and attached thereto by a metal eyelet formed of one piece with the former.—Patent completed.

2025 W. HEYES and W. BEVAN. *An improved self-acting buckle or coupling, to be employed for lifting, hoisting, or winding at coal pits, or for other similar purposes.* Dated July 10, 1867.

This invention consists in the use of a peculiar clasp or coupling which forms the connection between the cage, &c., to be raised, and the rope or chain employed for raising the same.—Patent abandoned.

2026 W. L. WISE. *Improvements in the manufacture of crossings for the permanent ways of railways.* (A communication.) Dated July 10, 1867.

In constructing crossings (which the inventor makes non-reversible) he takes blocks of steel, &c., in a cold state, and submits them to the action of planing machinery, so as to form grooves or recesses therein, to bring out in relief the various portions constituting the point and side rails, and other raised parts of the crossings, which he, in some cases, subsequently tempers, and to otherwise prepare them for use, the crossings being in one piece, and being so formed as to render them capable of ready renewal or repair by the simple process of planing. He fixes the crossings on the sleepers by bolts passing through the thickness of the metal, thus dispensing with the necessity for special chairs—at least, in so far as regards the intermediate sleepers.—Patent abandoned.

2027 W. E. NEWTON. *Improved apparatus for boring or perforating rocks, metals, or other substances.* (A communication.) Dated July 10, 1867.

This invention is not described apart from the drawings. —Patent completed.

2028 G. R. B. AMOTT. *Improved machinery for making bricks for building and other purposes, and of coal peat or other substances to be used as fuel.* Dated July 10, 1867.

This machine includes both a pug mill and a moulding apparatus. Mounted upon the bed of the machine is the pug mill, which is fitted with knives for working the clay, &c., and forcing it down towards the bottom of the mill. At the bottom of the pug mill cylinder openings are made to permit of two or more endless chains of moulds passing through the cylinder. These moulds are carried by tumblers or drums mounted in bearings at opposite ends of the machine, and they receive their traverse motion from the axle of one of the tumblers, which is driven by suitable gearing. As the moulds pass through the pug-mill, they are filled with the material to be compressed, the surplus of which is removed by the lip of the exit opening of the pug mill cylinder through which they pass. The filled moulds in passing along the bed severally come under the action of a compressing plunger and a discharging plunger, the former of which completes the moulding of the brick, &c., while the latter serves to discharge it from the mould on to a transverse travelling apron for delivering the bricks, &c., out of the machine. —Patent completed.

2029 A. H. BRANDON. *Improvements in wood-planing machines.* (A communication.) Dated July 10, 1867.

Here the inventor, according to one arrangement, places the timber to be planed on the table of a machine, and he advances it towards a rotating cutter by an upper feed roller turning in fixed bearings above the timber, and a lower feed roller let in the table immediately below the first, and beyond these rollers and above the timber he places transversely a cutter running at a high velocity, on either side of which, and parallel with the same, he also places guiding rollers to maintain the timber steady under the action of the cutter. In order that the feeding rollers may adapt themselves to any thickness of stuff to be passed through the machine; he terminates the under edges of the table in which the lower one runs in the shape of inclined planes, and by advancing and withdrawing horizontally two inclined planes on which the table rests he causes it to rise and fall vertically to the required extent.—Patent abandoned.

2030 A. H. BRANDON. *An improved circular saw machine.* (A communication.) Dated July 10, 1867.

This invention refers to a machine provided with two rotating circular saws, either of which can be brought to bear on the wood or other material to be operated upon. The patentee mounts each saw on the extremity of a shaft, and one of these shafts is mounted in bearings adapted to the extremities of two parallel levers, kept at a proper distance apart by a hollow sleeve shaft connecting them at their centre. The other shaft is mounted in bearings adapted to the other extremities of these levers. The sleeve shaft, with its levers, shafts, and saws, is mounted on a stationary shaft or bolt at such a distance below the table of the machine that the upper saw projects to the required extent. A small pulley is mounted on each of these saw shafts, so that the driving strap will always drive the upper one whilst the lower one will remain stationary; thus, by rocking or turning this apparatus on the stationary shaft as its centre of motion, either one of the saws can be brought into work.—Patent completed.

2031 J. STIRK and H. BYCROFT. *Improvements in refrigerators for cooling worts and other liquids, which improvements are also applicable to condensers used in distillation.* Dated July 11, 1867.

Here the patentees employ a series of flat tubes, between which the wort to be cooled passes, the said wort pursuing a zig-zag course from side to side of the case, or over and under each tube alternately; but instead of joining the said flat tubes together, they make each tube independent of the others. The tubes are separately fixed in the case, and communicate at one end by means of short pipes with a supply pipe which supplies them with water, and at bottom with an exit pipe, by which the water passes out of the tubes. To effectually employ the cooling power of the water, each of the flat tubes has a series of horizontal divisions by which the tube is divided into a series of zig-zag spaces, through which the cooling water has to make a tortuous passage, and by which it effectually absorbs the heat of the wort in contact with the outsides of the tubes. In consequence of the tubes being independent of one another, as described, they may be very readily removed from the case for cleaning or repair, and in case of repair, the removal of one or more of the tubes does not interfere with the action of the others, so that the refrigerator may be maintained in action while it is undergoing repair.—Patent completed.

2032 J. B. FRASER. *New or improved machinery to be employed in the manufacture of watches and chronometers.* Dated July 11, 1867.

This invention consists, first, in the arrangement and combination of parts of machinery for making the top and bottom plates of watches and chronometers—that is to say, the plates in which the pivots or axes of the wheel work; and, second, in the arrangement or combination of certain other parts of machinery for depthing, marking, and drilling the holes in the top and bottom plates in which the pivots or axes of the wheels work.—Patent completed.

2033 J. S. HENDERSON and J. MACINTOSH. *Improvements in the manufacture of cylindrical metallic cases, and in the machinery or apparatus employed therefor.* Dated July 11, 1867.

This invention consists in bending sheets of tinned iron plate to the required shape on cylinders, and in effectually soldering them whilst in the cylinders.—Patent completed.

2334 J. H. JOHNSON. *Improvements in the manufacture of refined sugar.* (A communication.) Dated July 11, 1867.

This invention relates to what may be termed the primary process in the manufacture of refined sugar, namely, to the melting or dissolving, and consists of a mode of converting sugar of one quality into solutions of different qualities, to be used in the manufacture of such classes of refined sugar as the peculiar quality of the solution or syrup employed is best adapted for. We cannot quote the details of the method.—Patent completed.

2035 J. H. JOHNSON. *Improvements in boots and shoes* (A communication.) Dated July 11, 1867.

This invention relates to certain improvements in boots and shoes, and has for its object the supporting or holding up the "shank" or "waist" of the soles of boots and shoes. In carrying out this invention it is proposed to combine a tempered steel blade spring with a plate or strip of untempered steel, or other suitable metal, the steel spring being secured at its centre by a rivet which passes through the metal strip, leaving the ends of the spring free to play upon the surface of the plate or strip when deflected by the bending of the sole. This combined plate and spring is inserted into the interior of the sole at the "shank" or waist, and secured at the end: by nails or pegs introduced through holes made for that purpose in the ends of the metal plate. The plate being of untempered steel, or of flexible metal, may be shaped to the sole without liability to fracture.—Patent completed.

2036 K. J. WINSLOW. *An improved method of conveying the rotary motion to axles of steam engines, and all machines and carriages where cranks are used.* Dated July 11, 1867.

This invention consists of a method of turning axles by means of two connecting rods acting on two ratchets hung upon movable bars, which bars have the same centre of motion as the axle to be turned. These ratchets work as ordinary ratchets upon a cogged or roughened wheel fixed on the axle. The connecting rods are forced backwards and forwards by the piston or other motive rod, and the ratchets being thus alternately lifted and depressed, act in the direction of the wheel, and communicate the required motion. By a simple contrivance by stops attached to the movable bars or otherwise the ratchets are made to act in the opposite direction and the reverse movement is communicated to the axle.—Patent abandoned.

2037 B. HUNT. *Improvements in the construction of bearings for machinery, agricultural implements, and carriages.* Dated July 11, 1867.

This invention has for its object to construct wooden bearings which will not wear oval, but will wear in an uniform manner. The bearings are constructed of wood with the end way of the grain placed at right angles to the axis of the running shaft, so as to receive the friction of the journals. On either side of the journal of the shaft there are two or more pieces of wood of the exact diameter of the journal, and hollowed out to fit, and above and under these two hollowed-out pieces is or are placed one or more other pieces of wood, by which the two hollowed out-pieces are held in position. Into one or both of these upper and under pieces is dovetailed a smaller piece of wood, so placed that the end of the grain may be presented to the journal.—Patent abandoned.

2038 W. E. NEWTON. *Improvements in the construction of the permanent way of railways.* (A communication.) Dated July 11, 1867.

This invention consists in effecting the rigid coupling together the ends of the rails by means of side plates or braces rigidly clamped to the rails, without the use of any bolts or other appliances, which penetrate and thereby weaken the stock of the rails.—Patent abandoned

2039 J. S. BURKE and B. BURLEIGH. *Improvements in the construction of sub-aqueous works and foundations.* Dated July 11, 1867.

The plan of operation is as follows:—The inventors construct a pontoon or floating vessel of steel, iron, wood, &c., having a bottom of any required form. The pontoon is to be worked by steam power, or otherwise, and to be provided with screw propellers and apparatus for guiding and fixing in position, and with pumps for air and water pressure, and all other necessary apparatus. They then construct in a dry dock a casing of wood or metal of such form as may be required for a section of the work or foundation of the work to be erected. The said casing is then filled with brickwork, masonry, or concrete. The water is then let into the dock, and the pontoon is floated immediately over the casing, to which it is lowered by the admission of water, or by the action of the tide, and then securely fastened, either by bolts, chains, slings, &c. The pontoon is so constructed that, when emptied of the water, it shall have sufficient floating power to lift the casing and its contents together, and float them into their permanent position.—Patent abandoned.

2040 E. HOHENBRUCK. *Improvements in breech-loading firearms.* Dated July 11, 1867.

This invention is not described apart from the drawings. —Patent completed.

2041 R. A. KENNEDY. *Improvements in doors and windows, and fastenings for the same.* Dated July 12, 1867.

This invention is chiefly applicable to the windows generally known as "French windows," and it consists in making the sashes so that they can be raised on their hinges above the bottom bead forming part of the frame. —Patent abandoned.

2042 J. NELSON. *Improvements in the casting of hollow and other firebars.* Dated July 12, 1867.

This invention consists in casting hollow and other fire bars in chills, and more especially the casting of the bars used in Juke's revolving furnace. By casting flat bars in "chills" or moulds of cast iron, or other metal, made in two or more pieces, the metal, when poured into the moulds, receives a sudden chill, which makes the casting harder and more durable.—Patent abandoned.

2043 J. B. E. G. PERRIN. *An improved smoke-consuming apparatus.* Dated July 12, 1867.

This apparatus consists of a cast-iron steam chest with flanges, and with an elbow pipe for the reception of the tube in communication with the generator. In the interior of the chest is a bronze pipe, round at the top, and conical at the bottom, which terminates in a flange by which it is bolted to that of the steam chest. A second pipe of brass, outside the above-mentioned one, and perfectly concentric with it, and furnished with a flange, is bolted thereby to that of the steam chest at the opposite end to that to which the bronze pipe is attached. A copper domed case covers these pipes, and is likewise bolted in conjunction with the brass pipe by means of its flange to that of the steam chest. In this outer covering or case, and on either side thereof, are two orifices for the admission and exit of a current of water which circulates in the space comprised between the case and the last named or brass tube, to prevent the apparatus from burning. At the top of the dome thirty small tie-pieces or screw-cut tubes are fixed, fifteen of which connect the semi-conical pipe with the case, and the remaining fifteen put the latter in communication with the brass pipe. This machine is fixed on the fire box; the suction of air in the semi-conical pipe is naturally produced by the drawing of the fire, and, escaping through the fifteen small tubes which connect the said pipe with the case or cover, mixes with the steam escaping from the other fifteen tubes communicating with the brass pipe and with the generator. By these means a mixture of steam and gas is produced of an uniform pressure, sufficient to produce the consumption of smoke.—Patent abandoned.

2044 E. H. BERNIER. *Improvements in safety apparatus for raising and lowering persons and weights in mines, applicable to other purposes.* Dated July 12, 1867.

We cannot here give space to the details of this invention.—Patent completed.

2045 F. WILKINS. *Improvements in apparatus for producing or increasing the light or heat from carbonized atmospheric air, gas, or gaseous mixtures, by the use of hydrocarbons oils, spirits, or other inflammable liquids or any mixture thereof* Dated July 12, 1867.

This invention is not described apart from the drawings —Patent completed.

2046 J. HARGREAVES. *Improvements in the manufacture of steel and soft iron from cast iron.* Dated July 12, 1867.

The patentee claims, first, the partial removal of the impurities of cast iron by the use of currents of air, together with the subsequent use of the said partially purified cast iron with oxidizing salts to complete the conversion of the cast iron into steel or soft iron, substantially as described. Second, the use of steel slag to effect the removal of the impurities contained in cast iron, substantially as described. Third, the use of iron heated by currents of air, with or without steel slag, substantially as described, for the manufacture of steel and soft iron by subsequent treatment with oxidizing salts.—Patent completed.

2047 W. B. HAIGH. *Improvements in machinery for tenoning wood.* Dated July 12, 1867.

This invention is not described apart from the drawings. —Patent completed.

2048 J. KELLETT. *Improvements in or applicable to steam boiler and other furnaces for the combustion or prevention of smoke, and economizing fuel.* Dated July 12, 1867.

This invention consists in constructing and applying to furnaces a cellular or hollow bridge behind the ordinary bridge. This bridge is open at the bottom, and the top is formed into gratings, or a series of openings, and (by preference) with the top or upper surface undulated or corrugated, and sloping towards the flame bed. The interior is divided by a series of vertical ribs or partitions, thus forming cells or passages for air which is admitted through the ash pit through an opening under the ordinary bridge provided with a door or flap for regulating the quantity to be admitted. Air passing through this bridge becomes heated by contact with the metal, and combining or mixing with the unconsumed products of combustion from the furnace, they become ignited thereby.—Patent abandoned.

2049 G. SINCLAIR. *Improvements in steam boilers and furnaces.* Dated July 12, 1867.

This boiler is constructed with two semicircular parts placed one above the other, connected together by vertical tubes. The front part, however, that is to say, the whole length of the furnace or firebox part, is of a cylindrical form wherein the patentee constructs one or two round furnaces, such front part being attached to the main part by two round or oval tubes, one at the top and the other at the bottom. He also adopts and uses two large tubes placed at the back end of the boiler for causing a circulation of the water in the boiler.—Patent completed.

2050 C. T. HIGGINBOTHAM. *An improved arrangement or construction of furnaces to be used for preventing smoke and effecting economy of fuel.* Dated July 12, 1867.

This invention consists in using firebars having a hollow web, or partly hollow and partly tubular web, which bars may or may not also have, in addition to the hollow or tubular web, certain lateral openings through which air may pass into the overlying stratum of fuel.—Patent abandoned.

2051 J. H. JOHNSON. *Improvements in apparatus for cutting or mincing meat, vegetables, and other substances.* (A communication.) Dated July 12, 1867.

The patentee claims, first, imparting to the cutter of mincing machines a chopping as well as a draw-cutting motion for more effectually cutting or dividing the substances to be operated upon, as described. Second, the arrangement of machinery for effecting a chopping as

Digitized by Google

well as a draw-cutting motion of the cutter of mincing machines, as described. Third, the construction and arrangement of machinery for imparting a continuous or an intermittent rotatory motion to the receptacle containing the substance to be minced, whilst such substances are being operated upon, substantially as described. Fourth, the general combination and arrangement of apparatus for cutting or mincing meat, vegetables, and other like substances, as described.—Patent completed.

2052 A. M. CLARK. *Improvements in the construction of lifeboats, and in detaching tackle for boats.* (A communication.) Dated July 12, 1867.

This invention consists, first, in applying a removable and replacable inflated cover to and over the hold of a lifeboat, and supplying the interior with fresh and removing the foul air from the enclosed space through a hollow and divided shaft or mast, so that the lifeboat cannot have any water thrown into it, and, consequently, cannot sink. Second, in combining with the detaching apparatus of a boat, whether arranged at or over the sides or centre of the boat, a bail, bar, or other crosspiece extending to and connected with the sides of the boat, so as to act as a brace against the tendency of the boat to tip when hastily or unevenly loaded.—Patent completed.

2053 J. PASFIELD. *Improvements in safety or relief valves.* Dated July 12, 1867.

This invention consists in a mode of constructing safety or relief valves, whereby they are made very sensitive to variations of pressure, and great facility is afforded for the rapid escape of surplus steam, air, or gas.—Patent abandoned.

2054 D. M. HENDERSON. *Improvements in the framing of lighthouse lanterns, and of the optical apparatus of lighthouses.* Dated July 12, 1867.

This invention is not described apart from the drawings. —Patent abandoned.

2055 A. E. HERRMANN. *An improved compound to be used for igniting fires.* (A communication.) Dated July 12, 1867.

This invention relates to the manufacture of an article moulded from a plastic compound of inflammable substances, the object being to produce an efficient fire kindler at a comparatively small cost. To this end, two mixtures, which may be designated A and B, are prepared separately and then combined by mixing together equal parts of the two. The compound thus produced is placed in moulds and heated, and it is then by pressure formed into cakes. To produce mixture A, to any given quantity of pulverized coal and pulverized charcoal (either or both), coal tar and resin are added in the proportion (say) of one-half (more or less) by weight, and stirred or pugged to form a homogeneous mass. To this mixture are added small proportions of mineral wax, known as ozokerite, and of nitrate, acetate, chromate, or sesquioxide of lead, or other product that will give off oxygen for quickening and maintaining combustion. In mixture B the same substances are used with the exception of coal and charcoal dust, for which sawdust is substituted.—Patent abandoned.

2056 G. T. BOUSFIELD. *Improvements in the manufacture of corsets.* (A communication.) Dated July 12, 1867.

This invention consists in constructing corsets of raw or partially tanned hide or parchment, which is drawn, when in a moist condition, over models or frames of such portions of a human figure as it is desirable to copy, and allowed to dry and harden in contact with the moulds or forms.—Patent abandoned.

2057 J. LAING. *An improvement in fastening wood to iron, applicable in securing the planking of composite ships to the iron frame.* Dated July 12, 1867.

When ordinary screw bolts and nuts are used to fasten a wooden planking to an iron frame, it is difficult to obtain sound and secure work, because the holes punched in the iron frame are taper, and, therefore, the bolt touches the frame only on a line of inappreciable width, even assuming that the hole is punched exactly of the proper size; hence the rigidity of the structure depends mainly on the nip of the nut against the frame. According to this invention the patentee employs nuts having a thin and somewhat taper ferrule formed on them on the under side, and this as the nut is screwed on enters the upper end of the taper hole, and when the nut is screwed home becomes jammed and ground into it so as effectually to fill the taper hole around the bolt.—Patent completed.

2058 E. B. BIGELOW. *Improvements in power looms.* Dated July 12, 1867.

We cannot here give space to the details of this invention.—Patent completed.

2059 P. M. A. LAURENT. *A certain improvement in nautical compasses.* Dated July 13, 1867.

Here the patentee obtains the stability of magnetic needles and compass cards by loading them with weights placed as far as possible from the point of suspension, and, on the other hand, he obtains more sensitiveness by loading the compass cards or needles with weights as near the centre as possible.—Patent completed.

2060 R. SIMS and J. PREST. *Certain improvements in agricultural apparatus, called horse rakes.* Dated July 13, 1867.

This invention consists, first, in so constructing and arranging the apparatus that the "lifting bar" of the rake shall be above the teeth of the rake, by which the hay is prevented from lodging on the bar and becoming scattered behind the rake where the ground should be clear, and the trouble of disengaging the hay from the bar is also avoided. Second, the invention is designed to allow a portion of the teeth to fall into hollows when passing over uneven ground. This is effected by means of joints on the "rake bar," and the employment of a counterbalance weight which assists in more readily releasing the rake when full from the load of hay it gathers.—Patent abandoned.

2061 J. WALKER. *Improvements in the manufacture of clips or spring bears for railway and other carriages, and in machinery or apparatus to be employed therein.* Dated July 13, 1867.

We cannot here give space to the details of this invention.—Patent completed.

2062 W. DRURY and C. WESTRUP. *Improvements in the means of indicating numbers and names on doors of private houses.* Dated July 13, 1867.

Here the patentees cast the head of a street door knocker, which is usually of solid metal, with a round, oval, or other shaped opening, and in the back of this opening they insert a ground or other glass tablet, having thereon the number of the house inscribed. An aperture of similar form is also made through the door immediately behind the tablet in the knocker head. In this manner the number may be readily discerned on the transparent tablet from the street at all times, and especially at night, by the light of the hall or passage lamp, or from other source.—Patent completed.

2063 T. BERNEY. *Improvements in apparatus for bending bars and plates of metal, and for forming and working metal, and in the converting, for purposes of this invention, of apparatus already in use.* Dated July 13, 1867.

An extension of time for completing this patent having been petitioned for, the documents relating to the invention cannot at present be seen.

2064 H. BELL. *Improvements in heel tips and toe tips for boots and shoes.* Dated July 13, 1867.

Here the inventor gives to the iron or metal, of which the tips are made, a less thickness at that part which forms the inner edge of the tip than that part which forms the outer portion of the tip, and he makes the holes for attaching the tip in the thin part.—Patent abandoned.

2065 H. FLETCHER. *Improvements in apparatus for the manufacture of artificial fuel, which apparatus may also be employed for other purposes.* Dated July 13, 1867.

The object of this invention is to construct an apparatus for drying and heating coal, and mixing the coal with pitch simultaneously; or the coal may be first heated and dried, and subsequently mixed with pitch in another operation. The adhesive substance may be farina or silicate of soda, where heat is not required, and the apparatus acts only as a mixer.—Patent completed.

2066 H. DUKE. *Improvements in apparatus for reefing and furling ships' square sails.* Dated July 13, 1867.

This invention relates to various improved arrangements and combinations of parts for facilitating the performance of the operations of reefing and furling ships' square sails from the deck, when such sails are so connected that they can be made to rotate and wind on or off, or furl or unfurl the sail, whenever required. We cannot here produce the details of the invention.—Patent completed.

2067 E. T. HUGHES. *An hydraulic self-acting vent peg.* (A communication.) Dated July 13, 1867.

This invention is not described apart from the drawings. —Patent completed.

2068 J. C. RAMSDEN. *Improvements in reeds and healds used in weaving.* Dated July 13, 1867.

This invention consists, first, of special means for manufacturing the reeds used in looms for weaving; and, second, in certain improvements in lapping the stones or shafts upon which the healds or heddles are put when used in weaving.—Patent abandoned.

2069 J. SCOTT. *Improvements in fire-escapes, the same being applicable to other useful purposes.* Dated July 13, 1867.

This invention has reference to two former patents, dated respectively October 31, 1866 (No. 2816), and April 18, 1867 (No. 1159). The specification of the invention is too elaborate to be quoted here at sufficient length for an intelligible abstract.—Patent abandoned.

2070 J. G. TONGUE. *Improvements in the construction of instruments or apparatus for ruling parallel, angular, and curved lines.* (A communication.) Dated July 13, 1867.

This invention relates, first, to the construction of an instrument or apparatus termed a "micrographic" rule. The instrument consists of two rules of wood, metal, &c., connected at or near their extremities by jointed arms, which are connected together at the joints by a rod or link which retains the arms opposite to each other. Upon or near the middle of one of the parts of the rule a suitably divided transverse bar is mounted, and this bar moves on a guidepiece fixed on the other rule. It is by the aid of this divided bar that the distance is determined that one of the rules moves in regard to the other. The equal parallel distances required may be exactly obtained by means of a small movable sliding piece which can be fixed when desired upon the divided bar by a thumbscrew, and the sliding piece is brought against the connecting rod or link previously described when one of the rules is moved away from the other, consequently limiting the distance that the other rule can move. It is evident that this distance will be changed by altering the position of the sliding piece. Other forms of stops for arresting the movement of the rule may be employed for the above purpose. Guides are placed at the extremities of the two rules to render their parallelism more perfect. In addition to the instrument previously described, apparatus may be combined therewith (or made separate therefrom) for ruling angular and curved lines, each instrument being termed a "micographic geniographe."—Patent abandoned.

2071 J. L. NORTON. *Improvements in apparatus for drying grain seeds, malt, spent hops, brewers' and distillers' grains, hops, wool, rags, and any other materials.* Dated July 13, 1867.

The first part of this invention consists of a cylinder with a steam casing or jacket around it, and it may be made to revolve or remain stationary. The patentee prefers it stationary. When the cylinder is caused to revolve, it has a series of shelves fixed inside, which take up the material to be dried, and allow it to fall in showers, and a backward or forward movement is given to the material by its falling against directing plates. The directing plates may be either fixed to a shaft in the centre of the cylinder, or they may be arranged on the shelves which carry the material. The cylinder is driven from the outside with suitable gearing, and it runs on friction rollers. The material is fed in at one end of the cylinder and delivered out at the opposite end.—Patent completed.

2072 I. BAGGS. *Improvements in the construction of washing-basins and other utensils for holding liquids.* Dated July 15, 1867.

This invention consists in the application of a syphon to washing basins and other utensils for holding liquids, whereby their contents are either retained or discharged at pleasure by merely effecting an alteration of the level of the liquid.—Patent abandoned.

2073 T. WRIGLEY. *Certain improvements in pulley and chain gearing to be employed for lifting or traction purposes, for moving fire-bars in furnaces, or for driving mechanism.* Dated July 15, 1867.

The patentee claims the employment and use of pulleys, constructed as described, in combination with chains as constituting positive or non-slipping gearing, for lifting, traction, driving, or other similar uses; and, second, the application and use of firebars in furnaces attached together by endless chains and moved by such arrangement of pulleys and links in which the pins of the links constitute part of the firebars, as described.—Patent completed.

2074 G. BOEHM. *The combination of a bottle and compass.* Dated July 15, 1867.

Here a flat-sided bottle, preferably of about the contour of a watch, is taken, and a compass card and needle are inserted therein (during the making of the bottle or otherwise) and are arranged so as to face one of the flat sides of the bottle. Sand or other material is then put into the bottle, which is stopped in the ordinary manner, and which may be ornamented as desired.—Patent abandoned.

2075 F. D. NUTTALL. *Improvements in the construction of furnaces employed in the manufacture of glass.* Dated July 15, 1867.

The main objects of this invention are, first, to economize fuel; second, to obtain any desired temperature for heating or fusing; third, to render the most important parts of glassmakers' furnaces more durable. The tank is made of fireclay bricks or blocks, or of fireclay or pots in any ordinary way, and is supported on pillars or walls with space between. These pillars or walls and spaces constitute the "cave." The firegrate or fuel chamber is formed at the side of the tank, preferably at some distance therefrom, in such manner that only a limited supply of oxygen is admitted to or amongst the fuel. The gaseous product of the partial or slow combustion of the fuel induced in this way passes along a flue, and when just over the tank, or before it reaches it, heated air is admitted, and intense combustion thereby induced. The volume of heated air admitted determines the temperature in the tank and flues. The heated air is taken from the "cave," when it is raised in temperature by radiation, or from pipes which are passed through or over the firegrate or fuel chamber.—Patent completed.

2076 J. M. HETHERINGTON and R. W. PITFIELD. *Improvements in machinery for preparing and spinning or doubling cotton and other fibrous materials.* Dated July 15, 1867.

In reference to carding engines the patentees claim, first, causing the triggers to revolve in two or more planes, and mounting the parts against which they act so that they may be brought into any of those planes. Second, in reference to those flats which are mounted on endless chains or bands, they claim adapting a strip to one flat, which strip overlaps an adjacent flap. In reference to the mule they claim, first, bringing the adjustments described to one side of the headstock. Second, stopping the spindles by the direct action of a cam on the twist shaft upon the band of the brake. Third, in reference to the change motions taking the weight required for effecting such changes from the carriage puts on when running in, they claim the adjustable roller mounted on a lever attached to the carriage. Lastly, they claim the general combination of parts described.—Patent completed.

2077 J. BRIERE. *A continuous self-acting condenser, being an improved boiler feeding apparatus.* Dated July 15 1867.

The law which governs this invention is the equilibrium of liquids. The apparatus, filled with water placed above the level of the water of the boilers, allows its contents to flow through, the equilibrium of pressure established by steam coming from the boiler that has to be fed, the level of the water being regulated by the level of the steam pipe.—Patent abandoned.

2078 A. B. IBBOTSON. *Improvements in the means or mode of ventilating the interior of railway and other carriages, cabins and holds of ships, and other enclosed spaces.* (A communication.) Dated July 15, 1867.

The patentee claims, first, the use and combination of a screw ventilator with a fan made self-acting by the atmospheric current produced by the motion of railway or other carriages or vehicles, or ships or other floating vessels, for ventilating the interior thereof by the eduction of the air or vapour therein at or near the lowest level (or other part) thereof. Second, the use and combination of a screw ventilator with a fan made self acting by the force of the air in motion for ventilating stationary enclosed spaces by the eduction of the air or vapour therein at or near the lowest level (or other part) thereof. Third, the use and combination of a screw with a fan for the same or similar ventilations or purposes, the screw or fan being driven as described, or otherwise, by pneumatic or other power, and the motion of the screw being faster or slower than that of the fan, or equal thereto or therewith.—Patent completed.

2079 T. REDWOOD. *Improvements in the preservation of meat and animal substances.* Dated July 15, 1867.

We cannot here give space to the details of this invention.—Patent completed.

2080 J. T. SKINNER. *Improvements in apparatus for facilitating communication between the guard and the passengers in a railway train.* Dated July 15, 1867.

In order that the guard may be able to pass safely along a railway train whilst in motion, the inventor fixes on the side of each of the carriages, just over the tops of the doors, a horizontal bar, by preference of tubular form, and connects these bars together from end to end of the train by connecting pieces of wood, which are conveniently arranged to enter the ends of the tubular fixed bars. On the continuous guide so obtained, a small frame mounted on wheels or friction pulleys is able to traverse, and this is connected by a strap, or otherwise, to the person of the guard, who, thus supported, is able to walk with perfect security along foot boards on the carriages.—Patent abandoned.

2081 J. FLEMING. *Improvements in apparatus for drawing or raising beer, and other malt liquors, to a higher level than that of the cask.* Dated July 15, 1867.

The patentee claims the adoption of compressed air as a means of raising beer and other malt or spirituous liquors from the lower to the higher level.—Patent completed.

2082 F. B. VALLANCE. *Improvements in lamps for burning hydrocarbon, alcohol, and other spirits, animal and vegetable oils, and other inflammable liquids.* (A communication.) Dated July 16, 1867.

The patentee claims, first, the division of the chamber of lamps for burning hydrocarbon, essential and mineral oils, alcohol, ether, turpentine, and other spirits, animal and vegetable oils, and other inflammable liquids, into two or more distinct compartments by means of a partition or partitions, one compartment, or set of compartments, forming the reservoirs which are cut off entirely from direct communication with the external air by means of the interposition of the hollow or vaporization chamber or chambers and the partition or partitions.

Digitized by Google

Second, the construction of the partitions, which are made either of metal (in such case having an aperture in which is closely fitted a supply wick of some meshy or porous material which will cause capillary action) or the construction of the partition and wick of one material including such action; or the construction of the partition of perforated plates having granulated, filamentary, or porous material between them. Third, providing partitions when necessary with self-closing spring valves, or a self-closing spring valve, thereby preventing the accidental escape of the liquid whilst such escape being rendered impossible. Fourth, the substitution of a conical or taper fit for the top or cover of the lamp, thereby dispensing with the screwing of the same as is now necessitated.—Patent completed.

2083 H. G. DUNN. *A new apparatus and method for the saving of life and property from fire.* Dated July 16, 1867.

This invention is not described apart from the drawings. —Patent abandoned.

2084 J. FRASER. *Improvements in machinery for printing consecutive numbers.* Dated July 16, 1867.

The object of this invention is to provide machinery or a machine by which sheets of consecutively numbered tickets, cheques, or forms can be printed without removing the sheet of paper or tissue from the machine. This is effected by printing line after line of numbers the full width of the sheet from the top downwards.—Patent abandoned.

2085 G. W. HAYES. *Improvements in machinery for making paper.* Dated July 16, 1867.

This invention is confined to that portion of paper-making machinery called the strainers or knotters, which machinery varies in construction, and this invention is applicable to all such as receive the supply of pulp on the upper surface of the plates. In the manufacture of paper it is found that the uniformity of the paper is interfered with by the accumulation of knots and impurities on the surface of the knotter plate; when the surface of the plate has just been cleared and free from knots and impurities, more pulp passes through it than was passing before the plate was so cleared, and a corresponding variation in the thickness of the paper occurs. Now, according to this invention, the patentee divides the surface of the knotter plate by suitable partitions, so as to form a comparatively narrow zig-zag channel over its surface, along which the pulp has to flow until it gets through the plate. The supply of pulp being introduced on to the surface of the knotter plate at one end of this zig-zag channel, a current will be found sufficient to carry the knots and other impurities which are too large to go through the opening of the knotter plate to the further end of this zig-zag channel, when they will be deposited, and whence they can be removed at leisure, leaving the greater portion of the plates free for the passage of the finer portions of the pulp, and, consequently, allowing a flow through the clear portion of the knotter plates of a practically uniform quantity.—Patent completed.

2086 J. MANNOCK. *Improvements in scrapers for cleaning boiler tubes.* Dated July 16, 1867.

This invention refers more especially to tubes arranged vertically in the flue for heating the feed water. The scrapers are formed in two or more segments, which segments are carried in a suitable cup or holder encircling loosely the tube to be cleaned; the bottom of the cup or holder is formed with an inclined surface, and the under side of the scraper is formed with a corresponding incline; by these means the segments of which the scraper is formed will at all times be in contact with the surface of the tube, the weight of the scrapers tending at all times to keep them in action. The segments may be formed with any suitable scraping edges, and the cup or holder for containing them may have holes formed in its under-side to prevent choking.—Patent completed.

2087 W. M'ANDREW. *Improvements in machinery for ginning cotton.* (A communication.) Dated July 16, 1867.

The patentee claims combining with a ginning roller and doctor or fixed blade a beater bar with beaters or teeth upon it, such bar moving to and fro in a direction parallel to the axis of the ginning roller, as described.—Patent completed.

2088 T. PIRIE. *Improvements in agricultural implements.* Dated July 16, 1867.

In carrying out this invention the greater part of the weight of the implement is supported or carried upon wheels so that the sole and side plates are dispensed with, by which means the great friction attendant upon the sole and side plates is avoided to such an extent that a pair of horses can draw the improved plough cutting two furrows at once of uniform depth and breadth for about the same expenditure of energy required to draw a plough as hitherto constructed cutting only one furrow at a time. The cutters and mould-boards are jointed to an angular framework, so that they can be shifted in position to cut any required breadth of furrow by means of adjusting screws; the wheels are also jointed thereto by means of movable levers, so that the plough may be raised or lowered and guided in the required course. These levers are again provided with screws for adjusting them in the shortest time without the necessity of stopping the horses. The axle of the leading wheel of the plough is attached to another lever, so that when the lever is raised by the attendant, the wheel can be set inwards or outwards, as may be necessary, and when adjusted the lever is again lowered for securing the joint. The leading wheel runs in the bottom of a previously cut furrow, whilst a wheel on the opposite side of the plough carries or supports that side, and a hind wheel is attached to a movable mould-board, the position of the hind wheel and leading wheels regulating the depth of the furrow.—Patent completed.

2089 H. A. BONNEVILLE. *Improvements in the permanent way of railroads.* (A communication.) Dated July 16, 1867.

This invention is not described apart from the drawings. —Patent completed.

2090 H. A. BONNEVILLE. *Improvements in brushes.* (A communication.) Dated July 16, 1867.

This invention is not described apart from the drawings. —Patent abandoned.

2091 T. W. R. WEBSTER. *Loading any number, description, or size of cartridges used in breech-loading guns, with safety, rapidity, and precision, and with any charge, variable at pleasure.* Dated July 17, 1867.

This invention is not described apart from the drawings. —Patent completed.

2092 T. ARCHER, JUN. *Improvements in machinery or apparatus for crushing and pulverizing ores, stones, and other hard substances.* Dated July 17, 1867.

The patentee claims the combination of parts consisting of a roller with a squeezer having curved acting faces, such roller and squeezer being driven by suitable gearing, so as to impart a revolving motion to the roller, and at the same time a short and powerful vibratory motion to the lever and squeezer, as described.—Patent completed.

2093 C. M. TATE. *Improvements in button fastenings, for attaching buttons or ornaments to garments.* Dated July 17, 1867.

This invention is not described apart from the drawings.—Patent completed.

2094 G. WEEDON. *Improvements in knife cleaning machines.* Dated July 17, 1867.

This invention relates to reciprocating machines, and consists in certain arrangements for holding the knives whilst they are being cleaned, for reversing or turning them over from one side to the other, and in a novel form of construction of brush. The details of the invention are too voluminous to be produced here.—Patent completed.

2095 J. SCHOFIELD and J. C. DAWSON. *Improved means and apparatus for malting or drying barley, part of which means and apparatus is also applicable to other purposes.* Dated July 17, 1867.

Here the inventors place under the dryhouse floor one or more series of layers or coils of pipes. These pipes they heat by means of steam supplied from a steam boiler, causing such steam to circulate rapidly through the pipes, and thus heat the atmosphere surrounding them and passing through the dryhouse floor, where the barley to be malted is laid.—Patent abandoned.

2096 A. DE SMET. *Improvements in means of communicating motion to the spindles of spinning, roving, doubling, twisting, winding, and other similar machines.* Dated July 17, 1867.

The patentee claims a mode of communicating motion to the spindles of spinning, roving, doubling, twisting, winding, and other similar machines, by means of friction wheels or rollers, substantially as described.—Patent completed.

2097 J. SLATER. *Improvements in steam generators and condensers.* Dated July 17, 1867.

Instead of the circular flues now used in Cornish and other boilers, the inventor inserts square or rectangular flues filled with rows of tubes, which rows are made to cross each other at angles, whereby a greater quantity of the most efficient heat-absorbing tube surface will be presented to the current of the flames than is effected by any other arrangement of tubes.—Patent abandoned.

2098 G. H. DAW. *Improvements in cartridge pouches or carriers, and also in rifle sights.* (A communication.) Dated July 17, 1867.

Here the patentee employs a flexible pipe of leather, &c., connected at its two ends with a metal mouthpiece. This mouthpiece consists of a central tube, having upon it on opposite sides two short branches inclining upwards, and to these branches the ends of the flexible pipe are adapted. Within the central tube is another tube with an opening on one side, which, by turning the interior tube partly round, can be brought to correspond with one or other of the branches of the outer tube. The lower end of the interior tube projects from the outer tube, and has jointed to it on opposite sides two lever catches. On the outside of this tube, over these catches, is a slide, also of a tubular form, with projections upon it, which, by moving the slide on its tube, may be brought in contact with the lever catches on one or other side of these centres or axes, so as to cause them to rock thereon. There is a helical spring which tends constantly to draw the slide upwards, and then the upper ends of the catches project within the tube, but when the slide is drawn down the catches are caused to tip on these centres, and the upper ends of the catches are withdrawn, whilst the lower are caused to project into the tube. The apparatus is worn like a cross belt over one shoulder with the mouthpiece by the side of the wearer. The cartridges, which are supposed to be those of a breech-loading arm with flanges at the back, are filled into the flexible pipe through openings left for the purpose, and they tend to descend by their own weight towards the mouthpiece, and on the side on which the said opening of the interior tube corresponds with the branch forming a continuation of the flexible pipe, the lowest cartridge passes down into the interior tube until its flange is caught by the upper ends of the lever catches, and it is there held until by moving the slide down the upper ends of the lever catches are drawn back, and the cartridge then falls until its flange comes against the lower ends of the same catches, where it is held until the slide is allowed to rise by the action of its spring; and then, the lower ends of the lever catches being drawn back, this cartridge falls out into the hand of the operator, whilst the cartridge next above descends until its flange is stopped by the upper ends of the lever catches, which now again project, and so this cartridge is held ready to be discharged when the slide is next moved. When one side of the flexible pipe is discharged, the inner tube is turned half round to bring its opening to correspond with the branch with which the other side of the flexible pipe is in connection.—Patent completed.

2099 S. C. LISTER. *Consuming smoke, economizing fuel, and generating steam.* Dated July 17, 1867.

The first of these improvements consists in admitting the steam, or steam and air, at the bridge, and in order to mix it properly with the gases in the furnace the inventor prefers to blow the steam and air through a number of tubes (pierced with holes) in the flue. Secondly, in forcing a current of air, or air and steam, through hollow grate bars pierced with holes at intervals, so as to blow the fire with air or air and steam combined.—Patent abandoned.

2100 J. H. JOHNSON. *Improvements in the treatment and purification of oils.* (A communication.) Dated July 17, 1867.

Here the oil (such as colza or other oils) is placed in a boiler, and to it is added gradually a solution of a caustic alkali, such, for example, as soda; the two are then well agitated, and after thorough incorporation has been effected, the temperature is gradually raised to about 200deg. Fah., taking care not to exceed by many degrees this point. By the application of heat, the coagulated impurities concrete and subside, and their separation may be effected by filtration or otherwise, and the oil, after having been allowed to cool, is filtered in the ordinary manner, and is then ready for the market.—Patent abandoned.

2102 C. KLUG. *An improvement in the preparation of chocolate and cocoa.* Dated July 17, 1867.

This invention consists in the application of malt, barley, and salep in the manufacture of chocolate or cocoa. These ingredients may be employed in the form of paste, flour, cakes, or tablets.—Patent abandoned.

2103 W. R. LAKE. *Improvements in looms for weaving.* (A communication.) Dated July 17, 1867.

This invention relates to a mode of controlling the operations of the picker staffs, which are connected or disconnected from their operative devices by the action of the shuttle upon the shuttle box binders. The latter are forced outward by the shuttle when the same is in the box, and form the medium through which the suspension or action of the picking is made to depend upon the presence of the shuttle in or its absence from the box. The patentee prefers to arrange the controlling or governing mechanism so that the picking on each side of the loom is stopped by the presence of the shuttle in the shuttle box on the opposite side of the loom. When this arrangement is adopted the accidental meeting of the shuttles on the race is prevented, as the picking on both sides of the loom is stopped by the presence of a shuttle in each shuttle box. —Patent completed.

2104 N. J. O. STUBBER. *Improvements in the mode of treating flax, hemp, and other fibrous plants for the purposes of spinning.* Dated July 18, 1867.

Here, when the flax or other fibres are cut to the lengths required for spinning, the inventor passes them under or between a heavy corrugated or grooved metal roller, the raised or convexed ribs of which work into the hollow or concave ribs of a metal roller of less diameter, for the purpose of crushing or breaking the straw or woody substances of the plants containing the fibres. By this process the fibres are released, and can be taken direct to the ordinary carding engines, and be worked, cleansed, cottonized, and brought to any state of fineness without being scutched, hand dressed, or hackled.—Patent abandoned.

2106 A. MORTON. *Improvements in the lateral action or induction of fluids, and in the apparatus or mechanism employed therefor.* Dated July 18, 1867.

This invention consists, mainly, in the construction and arrangement of apparatus by which certain currents of either elastic or liquid fluids, or of gases, may communicate a simultaneous motion to other such fluids or gases by their lateral action or induction through a tube, increasing in area in a certain ratio to the diminishing pressure of the escaping or acting fluid, and the objects and advantages to be gained by the use of the invention are its application to steam engines and "injectors." We cannot here give the details.—Patent completed.

PROVISIONAL PROTECTIONS.

Dated November 2, 1867.

3086 W. E. Gedge, Wellington-street, Strand. An improved hat cover. (A communication.)

Dated December 5, 1867.

3460 S. L. Worth, Oxford-street, brush manufacturer. Improvements in step-chairs, ladders, and steps.

Dated January 20, 1868.

192 T. G. F. Dolby, Old Town, Clapham, manufacturing goldsmith. Improvements in feeding bottles.

Dated January 21, 1868.

203 E. Thomas, Cardiff-street, Aberdare, miners' safety lamp manufacturer. An improvement in the construction of miners' safety lamps, in such a manner as to enable petroleum or other mineral oils to be consumed therein, and for other purposes.

225 J. F. Spencer, Sunderland, engineer. Improvements in regulating and working the valves of steam and other engines.

217 W. E. Newton, Chancery-lane. Improvements in rotary, steam, and other engines. (A communication.)

Dated January 22, 1868.

225 C. E. Brooman, Fleet-street, City, patent agent. A new or improved mode of producing a colouring matter. (A communication.)

227 C. E. Brooman, Fleet-street, City, patent agent. A new or improved mode of extracting colouring matter from madder. (A communication.)

Dated January 23, 1868.

243 J. Goulding, Tong-street, Dudley Hill, Bradford. Improvements in looms for weaving.

Dated January 25, 1868.

262 J. and T. A. Boyd, Glasgow, engineers. Improvements in winding machines and in pirns or yarn holders and shuttles, a part of which improvements is also applicable to other machines requiring varying motions.

270 A. M'Dougall, London, manufacturing chemist. Improvements in apparatus for burning, calcining, or roasting, sulphur, ores, and other materials.

Dated January 28, 1868.

291 C. E. Brooman, Fleet-street, City, patent agent. Improvements in the manufacture of candles. (A communication.)

292 G. N. Sanders, Rue de Seze, Paris. Improved apparatus for regulating and increasing artificial light produced by the combustion of gas, oil, petroleum, and other volatile oils.

294 A. Pickering, York, printer. Improvements in machinery for cutting out, stamping, and embossing lozenges, jujubes, and various articles of fancy confectionery, and other articles, from soft or plastic substances or materials.

296 W. R. Lake, Southampton-buildings, Chancery-lane. An improved pavement. (A communication.)

298 J. Brown, Stockton-upon-Tees. Improvements in machinery for cutting or slicing wood, tobacco, or other fibrous substances.

300 A. C. Pilliner, civil engineer, and J. C. Hill, ironmaster, Oakfield Works, Newport. Improvements in machinery for obtaining motive power, applicable also to measuring, raising, exhausting, forcing, and compressing fluids.

303 W. H. Richardson, Glasgow, and W. Beardmore, Parkhead Lanarkshire. An improved process to be used in the manufacture of iron and steel, and improvements in the apparatus or means to be employed therefor.

304 W. Marsh, jun., Leicester, hire, ironfounder. Improvements in lasts for boots and shoes.

Dated January 29, 1868.

314 C. Riley, Whetstone, machine proprietor. An improved combined threshing machine frame.

Digitized by Google

316 W. E. Newton, Chancery-lane. Improvements in self-acting brakes for carriages. (A communication.)
318 J. H. Johnson, Lincoln's Inn-fields. Improvements in disintegrating, scouring, and cleansing raw wool and woollen fabrics. (A communication.)
319 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in furnaces or ovens for roasting ores. (A communication.)

Dated January 30, 1868.

320 B. Dobson, machine maker, W. Slater, manager, and R. Halliwell, foreman, Bolton. Improvements in machines for spinniug and doubling.
321 J. Radcliffe, Durham. Improvements in the manufacture of puddled iron and steel into finished bars, plates, or other forms.
322 J. Grimes, Leicestershire, engineer. Improvements in machinery or apparatus employed in the preparation or manufacture of the bottoms or soles and heels of boots and shoes.
323 H. Aland, Richard-street, Roupell-street, Lambeth, ironfounder. Improvements in rotary blowing fans for producing blast for furnaces and other purposes, which improvements may also be applied to air and gas exhausters.
324 M. A. Hamilton, Southampton-buildings, Chancery-lane. An improved apparatus for cutting bread, vegetables, and other substances.
325 W. Hartnell and S. Guthrie, Lincolnshire, engineers. Improvements in, or applicable to, steam and other motive engines, and to engines or apparatus for raising and forcing fluids or feeding steam boilers.
327 T. Rowan, Glasgow, chemist. Improvements in removing impurities, such as sulphur and phosphorus, from iron and other ores, and from coal.
328 B. Hayne, Mitre Tavern, Broadwall, Blackfriars-road. Improvements in the mode of connecting beer engine pipes with their taps.
329 W. E. Newton, Chancery-lane. Improvements in window sun blinds. (A communication.)
332 J. Thompson, Aldersgate-street. Improvements in feeding bottles for invalids and infants.
333 A. M. Clark, Chancery-lane. Improvements in adjustable wrenches. (A communication.)

Dated January 31, 1868.

334 C. H. Adames, Birmingham. Improvements in the manufacture of portable metal buckets or pails and tubs.
335 E. Fleet, East-street, Walworth, mineral water manufacturer. Improvements in apparatus for the manufacture of aerated liquids.
336 J. Walker, Beeston, near Leeds, mechanic, and J. Hudson, Bowling, near Bradford, beer seller. Improvements in machinery for turning and cutting wood and other substances.
337 J. H. Johnson, Lincoln's Inn-fields. Improvements in steam engines. (A communication.)
340 H. Chapman, Westminster Chambers, Westminster, civil engineer. Improvements in bolts, nuts, and washers.
341 J. Mitchell, jun., and G. T. Graham, Dundee, manufacturers. Improvements in apparatus for marking or cutting woven fabrics into lengths such as are required for making sacks.
342 E. Bolton, Warrington, Lancashire. Certain improvements in the manufacture of gunpowder and similar explosive compounds.
343 G. L. Scott, Manchester, engineer. Improvements in apparatus for steering ships.
344 S. E. Howell, Sheffield, engineer. Improvements in suspension bridges.
345 J. Livesey, Victoria Chambers, Westminster, engineer. An improved material that may be used as a substitute for glass.
346 J. Frame, Glasgow, engineer. Improvements in transmitting motive power, and in mechanism or apparatus employed therefor.
347 A. M. Clark, Chancery-lane. Improvements in steam engines, and in parts connected therewith. (A communication.)
348 G. Clarke, Southwell House, Lower Heath, Hampstead. Improvements in fire-escapes.

Dated February 1, 1868.

349 G. Moulton, Manchester, engineer. Improvements in pentagraph engraving machines, employed in the engraving of cylindrical or other surfaces.
350 J. V. Jones and G. J. Williams, Birmingham, manufacturers. Improvements in the manufacture of metallic tubes.
351 R. C. Smith, Edinburgh. Improvements in the arrangement or construction of sinks or similar apparatus.
352 H. Aitken, Falkirk. Improvements in treating iron ores or ironstones for the purpose of obtaining products therefrom, and in the means employed therefor; also improvements in the ovens or draw kilns for carbonizing iron ores or ironstones.
354 A. M. Clark, Chancery-lane. Improvements in the mode of utilizing and increasing the lighting power of gases and inflammable vapours, and in apparatus connected therewith. (A communication.)
355 D. Murray, York Chambers, Adelphi, Strand. Improvements in coverings for the head, mouth, and neck.

Dated February 3, 1868.

357 C. E. Brooman, Fleet-street, City, patent agent. Improvements in steam and water valves, cocks, and faucets. (A communication.)
358 B. Ford, Middlesborough-on-Tees, engineer. Improvements in hot air stoves for blast furnaces in the manufacture of iron.
359 J. Tolson, Dalton, Huddersfield, manufacturer. Improvements in means and apparatus for cleaning the cards of carding engines.
360 J. and W. Weems, Johnstone, Renfrew, engineers. Improvements in machinery for heating and drying grain, and other vegetable products, fabrics, fibrous materials, and other substances.
361 M. A. Wilson, Victoria-road, Kensington. Improvements in spring and other mattresses, couches, and cushions.
362 J. Combe and J. Barbour, Belfast. Improvements in machinery for hackling and scutching flax and other fibrous substances.
363 J. M. Domenech, engineer, and F. P. Jonte, cabinet maker, Rue Gaillon, Paris. Improvements in combined photographic apparatus for outdoor operations.
364 J. H. Johnson, Lincoln's Inn-fields. Improvements in the treatment of bones. (A communication.)
365 J. West, Raglan-road, Plumstead. An improved method of, and composition for, preventing the formation of scale in steam boilers.
366 C. Richardson, Gracechurch-street, City. Improvements in looms for weaving.
367 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in leggings or gaiters, and other like articles. (A communication.)
368 H. B. Wright, Albany-street, Regent's Park, dressing case maker. Improvements in apparatus for sweeping chimneys.
370 W. Wallis, boot manufacturer, and G. Mant, Inland Revenue officer, Birmingham. Improvements in stands or supports for lasts used in the manufacture of boots and shoes.

Dated February 4, 1868.

372 R. A. Jones, Aylesbury. An improved warming and ventilating vessel or apparatus, applicable to stoves and other heat suppliers.
373 E. Grether, Manchester, merchant, and M. Bailey, Huddersfield, india-rubber manufacturer. Improvements in machinery for cutting discs or washers of india-rubber and other substances.
374 J. Lewis, engineer, R. Alston, manager, and E. Alston, pawnbroker, Preston, Lancashire. Improvements in movable firebars.
375 L. Desens, Charing Cross, engineer. Improvements in the construction of miners' lamps.
376 J. Dewar, Kirkcaldy, doctor of medicine. Improvements in preserving animal substances for use as food.
377 R. Morton, Cambridge Lodge Villas, Hackney, engineer. Improvements in refrigerators or apparatus for cooling liquids, parts of which improvements are also applicable to distillation, surface condensation, and heating air for blast furnaces or other purposes.
378 E. A. Morgan, Paisley, thread manufacturer. Improvements in apparatus for spinning or twisting.
380 T. Cook, Penfold-terrace, Peckham, mechanical engineer. Improvements in raising or forcing liquids from casks, barrels, and other vessels or receptacles.
382 T. Scott and R. Mowat, Edinburgh. Improvements in lamps for burning paraffin and other hydrocarbon oils.
384 J. Webster, College-street, Chelsea. An improvement in the means of preventing incrustation in steam boilers and other vessels.
386 J. Pettman, Mounty-terrace, Eglinton-road, Plumstead. Improvements in percussion fuzes suitable for projectiles to be fired from rifled ordnance.

Dated February 5, 1868.

388 R. D. M'Kellen, Manchester. Certain improvements in machinery or apparatus to be employed in the manufacture of cotton and other balls.
390 R. J. Jones, Blue Pits, near Rochdale, timber merchant. Improvements in machinery for manufacturing clog soles, clog blocks, patten boards, and similar articles, and cutting welts.
392 M. P. W. Boulton, Tew Park, Oxfordshire. Improvements in propulsion and in aerial locomotion, and in apparatus connected therewith, parts of which are applicable to projectiles and to boilers.
394 W. E. Newton, Chancery-lane. Improvements in mowing and reaping machines. (A communication.)
396 H. Moore, manufacturer, and J. Hamilton, machinist, Aston, Staffordshire. Improvements in the construction of furniture expanders, and in machinery to be used in making the same, which machinery is also applicable to other manufactures.
398 J. Hay, Glasgow. A new method of roughing horses, and of constructing horse shoes.

PATENTS APPLIED FOR WITH COMPLETE SPECIFICATIONS.

Dated February 8, 1868.

436 J. A. Nicholson, Adelaide-place, London Bridge, ship owner. Improvements in water-closets, commodes, chamber and toilet utensils, and other articles in earthenware or glass, and in the mode or means of securing stoppers, corks, and other movable parts or fittings therein or thereto, also in protecting the bearing or supporting surfaces thereof.
442 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in split spikes. (A communication.)
443 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in railway switches, and in adjusting and signalling devices for the same. (A communication.)

Dated February 10, 1868.

444 W. B. Adams, Woodstock Lodge, Blackheath. Improvements in heating and welding metals in various forms, applicable to forts, vessels, buildings, and other structures and uses.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the "London Gazette," February 18, 1868.

2805 W. Low and J. Treadwell. Riveting the soles of boots.
2808 W. R. Lake. Machinery for making bolts. (A communication.)
2813 J. Smith. Moulding metal.
2822 J. H. Brown. Utilizing refuse animal matters.
2834 R. Reid and E. H. Craigie. Mattresses.
2840 W. Potts. Gaseliers.
2849 A. F. Hobhouse. Propelling vessels. (A communication.)
2850 W. R. Lake. Bunging barrels. (A communication.)
2855 E. Haigh. Hats.
2857 J. C. Wilson. Steam boilers.
2861 A. Helwig. Feed-water apparatus.
2870 R. F. Bare and J. Thompson. Conduction of fluids.
2872 H. A. Dufrene. Decorticating rice. (A communication.)
2878 B. Nicoll. Construction of buildings.
2889 M. A. F. Mennons. Transmitting signals. (A communication.)
2891 H. A. Bonneville. Threading needles. (A communication.)
2894 T. H. Baker and T. Woodroffe. Treating sewage.
2896 W. R. Lake. Construction of railways. (A communication.)
2903 E. Gessner. Fulling machines.
2904 W. E. Newton. Preparation of wood. (A communication.)
2910 E. Shaw. Hoods for perambulators.
2914 L. Hamel. Clipping figured nett.
2916 T. Bell and J. Richardson. Decorticating rice.
2924 H. Sharp and F. W. Webb. Smiths' anvils.
2942 A. F. Jalourеau and C. L. Lardy. Telegraphic cables.
2945 F. Adkins. Manufacture of hoes.
2955 J. Hunter. Permanent way of railways.
2958 C. Duncombe. Charging cartridge cases.
3036 M. Henry. Balloons. (A communication.)
3091 T. B. Cutts and F. W. Brooksbank. Manufacture of lace.
3150 R. Robinson. Manufacture of filtering paper.
3362 J. M'Farlane and G. Barker. Permanent way of railways.
3539 W. Richards. Firearms.
3561 J. H. Kidd. Battrice cloth.
3651 M. J. Rice. Heading nails.
21 J. Cox. Fastenings for sleeve links.
92 J. Lewtas. Blinds.
98 J. G. Tongue. Sewing books. (A communication.)
109 J. G. Tongue. Sizing carpets. (A communication.)
153 G. E. Reading. Busk fasteners.
161 S. and E. Burrows. Employing waste steam.
212 W. J. Coleman. Manufacturing beer finings.
257 T. L. G. Bell. Preparing oxide of iron.
278 G. Kellogg. Hats. (A communication.)
285 W. Tranter. Firearms.
299 R. J. Moser. Bellows. (A communication.)
307 W. Snell. Fireproof safes. (A communication.)
308 W. Snell. Fireproof powder magazine. (A communication.)
321 J. Radcliffe. Manufacture of puddled iron.
342 E. Bolton. Manufacture of gunpowder.
388 R. D. M'Kellen. Manufacturing cotton balls.
442 W. R. Lake. Split spikes. (A communication.)
443 W. R. Lake. Railway switches. (A communication.)
444 W. B. Adams. Welding metals.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list, who have given notice of their intention to proceed, within twenty-one days from the date of the "Gazette" in which the notice appears, by leaving at the Commissioners' office, particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed February 14, 1868.

2355 J. Day and W. Dorber
2358 R. Joseph
2367 M. Frow
2371 W. W. Pocok
2373 W. R. Goulty
2378 C. E. Brooman
2391 C. E. Hall
2410 J. G. Marshall
2511 W. H. Kitson
2537 D. Payne
2565 J. Whittome
2575 J. Davies
2749 T. Weston
3346 W. R. Lake
3500 W. R. Lake

Sealed February 18, 1868.

2374 T. Tunstill
2386 H. Cridland

THE

MECHANICS' MAGAZINE.

LONDON: FRIDAY, FEBRUARY 28, 1868.

THE UPPER COAL FIELDS OF PORT NATAL.

WE have never been among the alarmists with regard to the exhaustion of our coal fields, although, of course, we have not held that they are inexhaustible. Our belief has been that there are other fields to be discovered and wrought to aid in economizing our supply, which will naturally become more expensive as the workings get deeper. Then, again, we have the aid of mechanical appliances which are now being developed to promote the economic production of coal. Besides, we can't bring ourselves to think that Providence would leave the world to cold and darkness for half the year. Long before our coal begins to fail, we shall have discovered something to take its place, if needs be. Indeed, agencies are at work all around us tending in this direction, and if the means are not yet perfect, it may be only because the end is not imminent. We may be sure that man's necessities and requirements will be supplied—no matter in what form—from the earth, so long as the earth is able to sustain him. The human race will never die of cold, nor grope about in darkness, for want of the means to produce heat and light. In support of the first provision which we have stated we believe Nature to have made in undiscovered supplies, we have only to refer to the continental coal mines represented in the Paris Exhibition. It is surprising to find how enormously the local supply of coal on the Continent has increased of late years. In Prussia, especially, the quantity mined yearly far exceeds previous belief. It is also worthy of note that, although much of this coal is of an inferior quality, yet the ingenuity of Prussian, French and Belgian engineers has devised means and appliances to obviate its peculiarities, and to turn it to good account.

Bearing very forcibly upon this point—forming, indeed, a remarkable corroboration of our views—is the news which has recently reached us from Port Natal, of the discovery of vast fields of excellent coal in the upper districts of the colony. The importance of this cannot be over-estimated, especially as the quality is all that can be desired. It is an event which has given all Natal a new problem to discuss, and a new field of operation, which promises much for the future welfare and greatness of the colony. We believe that, up to the present time, nothing like a full or trustworthy description of these coal fields has appeared. It would seem, in fact, that a considerable amount of ignorance exists with regard to the physical conditions of the country in this locality. This deficiency is amply made good in the last number of the "Natal Mercury," which comes to hand teeming with information upon the all-absorbing topic. The facts have been supplied by authoritative and careful observers, and are as interesting as they are voluminous and important. From them we learn that Natal at its north-western extremity runs up into a triangular corner, a line drawn across which would mark the extent and situation of the county of Newcastle. On the north-west this division is bounded by the Kahlamba Mountains, a link in that chain of hills, beginning with the Mokattum, near Cairo, and ending with Table Mountain, at Cape Town, which traverses the eastern coast of Africa. In the gullies and streams at the base of this range seams of coal of various thickness crop out, and are in common use by such inhabitants as reside there. A spur of hills is, however, thrown out from the central chain, and runs in an easterly direction many miles until, towards the eastern angle of the county, it spreads into a large rolling plateau, known as the Plateau of the Biggarsberg. Upon the top of this table land no coal has been found, for the reason that it is covered with a bed of trap or basalt about 80ft. thick.

We here come to a singular feature in connection with the geology of this district. One of the principal scientific reasons which has been urged against the existence of coal in Natal has been the presumed fact that the formation of most of the hills belonged to the earlier periods, and that in accordance with the observations and conclusions of science made in other countries it was impossible to find coal among the primary rocks. Nor has coal been so found in Natal, so that geological conclusions remain undisturbed. The coal seams in this division are almost invariably found in sandstone—not the harder old red sandstone found nearer the coast, but a softer and newer formation. The distinguishing feature is that this bed of sandstone is frequently overlaid by a stratum of trap or basaltic rock of an assumed average thickness of about 80ft. This is found not only on the top of the plateau of the Biggarsberg, already mentioned, but also on the top of the many detached hills around, as well as on the top of the Kahlamba. The Platberg, near Harrismith, a township just over the western border of Natal, in the Orange Free State, situated on the top of the Kahlamba, affords an admirable index to the geological structure of the surrounding country. This mountain is a detached mass behind the town, rising to a height of somewhere about 1,400ft., and presenting in the cliffs that form its side a perfect exposure of strata. It is crested, as usual, with about 80ft. of basalt or trap, but beneath is at least 900ft. of sandstone, that depth being all that the eye can see. This is the common character of the lower district of Newcastle. The theory has been hazarded that this deposition of trap is the result of some gigantic power working at a remote distance, and pouring down over these lands this super-stratum of igneous rock. It has also been believed to result from volcanic action, but the fact that the stratification of the country has been found to lie with rare evenness and regularity forbids this conclusion.

We have already observed that coal has been long used by those who reside near the outcropping seams, of which there are a great number. In the southern extremity of the county, and to the north of the Highlands of the Biggarsberg, two or three seams open up. One of these is 3ft. thick, and another of about the same thickness crops out at a point a mile or more off and 500ft. higher up, thus leading to the inference that a large bed of coal exists there. The coal with which the late trials were made in Natal were obtained from the lower seam. The system of mining at present adopted is as simple as it possibly can be. The bed of coal forms the bottom of a stream, and the coal is picked and loaded into waggons which stand upon the mineral itself. The coal previously used has simply been that which Nature has revealed to man; the sweeping of rains and torrents down the hill sides has gradually washed away the upper stratum of sandstone, and laid bare the coal. Besides the seams to which we have alluded, four others have been found in the bed of the same stream. The gullies descend the hill-side in steps, and it is in these successive steps, rising one beyond and above the other, that the coal becomes visible. In some places the seam has been traced for a length of more than forty yards. Where not already washed bare, a loamy soil lies over the beds, and when this is once removed there is nothing to hinder the working of the coal. Another seam is reported in the vicinity of those already mentioned, and which is 8ft. in thickness. Twelve miles distant, with the spur of the Biggarsberg intervening and bisecting the country, the coal crops out again on the farm of another resident, where the seam is about 7ft. thick, another being found about four miles further. Turning westward, into a drier locality, where there are but few streams, no outcrops of any importance have as yet been found, although beyond that again, amongst the roots of the Kahlamba, the seams reappear.

So far the extent and richness of the Newcastle coal fields; let us now turn to the next important question of the quality of the products. There appear to be several varieties of coal, some containing sulphur, some yielding clinker, and others giving a large percentage of ash, and these facts have led to adverse opinions being pronounced upon the broad question. But admitting these diversities, it seems equally clear that large quantities of excellent coal do really exist. The coal which has been unfavourably reported upon ought certainly not to be taken as a criterion of quality, inasmuch as it has been taken from the beds of streams, having been acted upon by the sun and rain perhaps for centuries. From the trials made in the colony, it appears that Natal coal possesses qualities which are not found in English coal, to which they render it in some respects superior. Thus, for instance, some of the coal tried emitted intense heat and lasted a long time, leaving but a very small residuum in the shape of ash. A remarkable instance of the heat-giving properties of the coal is given. The district abounds in nodular limestone, large beds of which, 3ft. or 4ft. thick, may be seen in places. A farmer on whose land the coal crops out was recommended to burn these for lime. He did so, but the heat of the fire was so great that the limestones were fused, and another attempt had to be made. Maritzburg blacksmiths, with scarcely one exception, prefer Natal to English coal.

We have seen that there are vast fields of the mineral, and that, by proper selection, it is to be had of excellent quality; it now therefore only remains to look at its extraction and transport. In both these respects we have every facility offered, and the most favourable circumstances presented. Found as the coal is on the surface, in the beds of streams, rising terrace-like one above another, some of the costliest branches of mining enterprise will be avoided, and for many a year it will not be necessary to sink shafts to deep levels. Had the upper surface of trap to be penetrated the extraction would be a far more difficult and expensive matter, but as it is the seams can be entered and worked laterally from the sides of hills where they are found. We can hardly conceive circumstances more favourable to the rapid and easy development of a coal mine. Then with regard to the conveyance, it appears that the country has been fully surveyed in several directions as far as Maritzburg, and it is estimated that a line of railway—the only available form of transport—can be constructed for half a million. This amount would be less were it not for the hill country, but it may be made for less if the Mont Cenis system be adopted. Beyond Maritzburg the country is very easy, presenting no difficulties whatever. Such a railway would not be merely a mineral line: it would form the central highway of the colony. It would traverse a country where cereals can be grown, where sheep and cattle thrive, and where other capabilities yet undeveloped exist, and would thus command a considerable goods and passenger traffic. Besides, there are two large states beyond Natal, the producing powers of which are only checked by the difficulties of transport. They also possess large mineral resources, so that the prospects of a railway are exceedingly good.

Hitherto we have looked at the question of the Natal coal fields from a local stand-point

Digitized by Google

only, but, viewing it in a more general light, its importance is vastly increased. The discovery of coal is made just where the world's commerce and national interests so much need it. We are at immense expense in supplying our eastern possessions, our Abyssinian and other expeditions, and our fleet, with coal exported from our own shores. Here, at Natal, half-way to the east and the Antipodes, are coal fields waiting to be worked and utilized, and although the coal is at present found some distance up the country, there is a probability that it may yet be discovered nearer the port. Black shale, slightly bituminous, is common, and there is an outcrop of coal on the sea shore at Umhlali, thirty-five miles north of Durban, so that it is reasonable to hope for such a discovery. In the meantime, the colony undoubtedly possesses large and easily accessible deposits of excellent coal in the upper portion. Seeing the vast importance of the question to England, we would suggest her hearty co-operation in the development of this mineral wealth. Government should set on foot a thorough survey of the coal fields, and such further steps should be taken as may be necessary to promote the speedy realization of one of the greatest advantages we could possess. This discovery of coal is a matter upon which we heartily congratulate the Natalians, for we are bound to believe that it will, if acted upon with promptitude and vigour, subserve the highest interests of the colony.

DOCKYARDS OF THE MEDITERRANEAN.

IN resuming this interesting and instructive subject, we would observe that, in addition to ships of war and royal yachts, the workshops of the Mediterranean have materially assisted in furnishing a supply of vessels to commercial navigation, including a large number of paddle and screw steamers. Les Messageries Imperiales, and other French, Italian, Spanish, and Russian companies, have drawn frequently upon its resources. Among the numerous examples of that class of shipbuilding devoted to the interests of peace, must be noticed the steam transports specially designed for bringing to the shores of the parent country, the valuable mineral ores obtained in the neighbouring colony of Algeria. These transports, which are built for "The General Steam Transport Company," are, as may be expected from the nature of the duties they have to perform, exceedingly solidly constructed. They can carry 1,500 tons of ore, and yet reach a speed of nearly nine knots per hour. Their length over all is 230ft., and their breadth a little over 30ft. The nominal horse-power is 120, and the consumption of coal 1,250lb. per hour. Nine of these boats were turned out of the port, in the short space of fifteen months. Marine engines upon a large scale are also made upon these premises, those for the armour-plated frigate, "Marengo," belonging to the French navy, being the most remarkable. The nominal force is 950-horse power, and there are three cylinders, into the centre one of which, the steam is first introduced, whence it passes into the other two. By this arrangement a great economy is effected in the item of fuel, and the power so obtained is very uniform. A similar engine was fitted to the Prussian frigate, the "Frederic Carl." This vessel is plated all over; she has a length of 335ft., and a breadth from out to out of 55ft. Her armament consists of fourteen broadside guns of large bore, and two others upon deck. The hull is divided into five water-tight compartments; the teak backing is a foot thick, the plates connected to it are 5in. in thickness, and the cost was a little under a quarter of a million sterling. At La Seyne was manufactured some of the machinery employed at the present works in connection with the piercing of the Isthmus of Suez. That used for the purpose of excavating is termed an "elevator," and consists of a small iron bridge supported on an incline, towards the centre, by a truck running upon rails laid upon the bank, and at the lower end by a bridge floating on the canal. The bridge carries another truck, which can be manœuvred so as to readily receive the loaded skips from the dredge. It then mounts the incline of the bridge, taking the skips with it to the upper end, and empties them where the contents are required to form the slope. Steam is the motive power employed, and the average amount of stuff raised and tipped per hour is 250 cubic yards. This quantity, moreover, is raised to a height of nearly 40ft., and transported along a distance of 150ft., which will afford some idea of the work done by the machinery. The "elevators" are used only for raising and transporting dry stuff. When the material is freely saturated with water, other apparatus, somewhat similar in design, are put in action. The main agent is a dredge carrying a number of buckets upon an endless chain, and which are made of wrought iron. These dredges can raise 150 tons of stuff per hour, and empty them either into barges lying alongside for the purpose, or into long iron troughs specially constructed for the purpose, measuring upwards of 220ft. in length, and carried upon a bridge. In order to assist the process of emptying the stuff into these "couloirs," as they are named, a current of water is caused, by means of pumps, to act continually upon their sides, and wash down the semi-fluid mud.

With that regard which all foreign manufacturing and industrial companies display for the social welfare, moral condition, and sanitary prosperity of their employés, the directors and managers of the establishment at La Seyne, have founded four institutions for the benefit of the workmen. They comprise a relief club for the sick, founded before the formation of the company, and having for its object the gratuitous supply of medicine. and medical attendance to those who are incapacitated from work by illness. To ensure this aid in time of sickness the workman contributes when in full work a small proportion of his pay to the general fund, and can only obtain the benefits of the institution by so doing. An ambulance capable of containing twenty-four beds, was fitted up and put on service, during a time when the cholera attacked the employés at La Seyne with a considerable degree of violence. During three days, when the epidemic was at its height, the workmen fell down in convulsions upon the quays and elsewhere. This portable hospital was found to be so valuable, that after the cessation of the calamity, it was retained as a kind of supplementary infirmary to the establishment. About two years ago, the Company built a large commons room, where food could be purchased either in the bulk or by the meal, as might be desirable. Upwards of 900 men can dine at a time in this hall. The whole of the arrangements of this department is under the management of a certain number of "les sœurs de charité" who reside upon the premises. A free school for adult workmen is opened in the town, and the course includes reading, writing, grammar, arithmetic, geometry, algebra, and drawing. Five professors are charged with the entire superintendence of the school, and their efforts are rewarded by an annual attendance of nearly 400 scholars. The dockyards of Marseilles, Menpetti, Arence, and La Jetée are provided with similar advantages, towards promoting the advance of technical education, a subject almost totally neglected in our own county, the result of the neglect of which is becoming daily more apparent. We see ourselves competed with, supplanted, and totally distanced in those very branches of manufacture and industry, which we had for so long a period learned to regard exclusively as our own. The most sanguine person cannot but admit that the monopoly we once possessed in certain branches of constructive art is gone for ever, and that in all of them, we only now share with other nations, which we at one time scarcely dreamed of as competitors, but which we are now forced to acknowledge are neck and neck with us, in the eternal race for wealth, prosperity, and commercial pre-eminence.

RESUMPTION OF STORM SIGNALS.

A LATELY issued Parliamentary paper relative to storm warnings contains the correspondence between the Board of Trade and the Meteorological Committee which led to the resumption of the signals. So far back as July, the Committee had in contemplation a scheme of signals for weather reports, and they suggested that the Board of Trade should present to each station a complete set of signal shapes and gear, having themselves no funds available for the preliminary outfit of the stations. The Board replied that they had not funds at their disposal for the purchase of new signals, but that they would hand over to each station the signals, gear, &c., supplied under the direction of Admiral Fitzroy. In October, Sir F. D. H. Elphinstone addressed the Board of Trade on the subject. "When," he says, "these forecasts"

Were first established, they were received by the maritime community with incredulity and distrust; but gradually a different opinion gained ground: the wonderful accuracy of these prognostications led to a general reliance on their truth; and latterly, those who had been loudest in their disbelief were foremost in availing themselves of the caution they afforded. Wrecks are due to a variety of causes; first, to unseaworthy ships; second, to defective ground tackle; third, to collisions; and fourth, to the stranding of vessels which are caught, on a lee shore, in positions from which they find it impossible to extricate themselves. For the first cause no cure can be found but stringent surveys, and throwing the responsibility for loss of life and cargo on those who send such vessels to sea. It seems inconsistent that railway companies should be held responsible for the safety of passengers and goods, while others escape from the consequences of management far more reckless than any conduct that ever goes before a jury in case of accidents by railway. That this view is not unreasonable will be seen by reference to the number of shipwrecks which occur from no apparent cause whatever, but which clearly denote a state of total unseaworthiness in the vessels lost. The second cause has been much mitigated by the operation of the Bill for testing chains and anchors, which I introduced into the House of Commons in 1860, and which became law in 1865, after experiencing much difficulty and opposition. It is to the third and fourth causes of wreck that the warnings originated by Admiral Fitzroy especially apply.

By far the largest portion of wrecks which take place in Great Britain are on the east coast, and the storm warnings were of the most importance at the coal ports of the north. From these harbours large fleets of deeply-laden vessels, often ill-found and under-manned, are continually putting to sea. The prevailing winds in these islands are from S.W. to N.W., but the sudden shifts of wind in the winter months from N.W. to E. and E.S.E. are the circumstances which often endanger the safety of large fleets. For example, ships leaving the Tyne with the wind at W. or N.W. of moderate force, naturally keep under the land, and endeavour to round Flamboro' Head at a distance of three to four miles; they then have a clear sea before them till they make the coast of Norfolk; but while they are quietly making their way to the southward, a violent storm from the east may be working its way across the North Sea, which will reach them before they can clear the Yorkshire land, and strew the coast with their wrecks.

This is no extravagant or unusual case; it was unfortunately of periodical occurrence, until Admiral Fitzroy's warnings gave timely notice of the approach of such sudden changes, and enabled precautions to be taken which were the means of saving much life and property. The discussions on the subject last Session left the impression on my mind that the authorities considered Admiral Fitzroy's warnings to be couched in more positive language than the information at his command warranted him to assume; be that as it may, his forecasts, though probably they owed some of their authority to his own experience and sagacity, had proved so generally correct, and were so extensively believed in and acted upon, that it was much regretted by practical men, as well as by men of science, that they had been discontinued.

In forwarding a copy of this address to the Meteorological Committee, the Board of Trade inquired whether they were prepared to issue cautionary notices of storms, and, if so, of what description, on what basis, and

Digitized by Google

on what terms. The Committee replied to the effect that a system of weather telegraphy had been approved by them, and that the specimen signals would be tested, for a short time, at one or more of our chief ports before being issued to the public. These signals consist of a semaphore similar in principle to a railway signal post. Until the new system of signals in preparation by the Committee is complete, they propose to use the drum as a cautionary signal to indicate the existence of a gale. The basis on which such notices were to be issued would be the study of the daily weather reports, as the self-recording observatories were not yet at work. We do not believe it possible that the Committee will ever obtain any data from these observatories which can be turned to immediate practical account in forecasting atmospheric disturbances. The recording agent being photography, the records cannot be consulted at any time previous to the removal of the paper and the fixing process, and data available for storm prediction are of little value when a day or two old. As to the terms of issuing the signals, the Committee suggested that the entire cost of transmission of messages should be defrayed by the Meteorological Office. The Committee signified their readiness to issue such notices as soon as arrangements could be made for hoisting the signal. Such a signal, said they, would be simply of a warning nature, and without conveying the impression that the storm would necessarily strike the port where it was hoisted, would imply that extra caution in navigation was requisite.

The plain meaning of this is that it is not intended to forecast gales, but simply to announce them. Probably, General Sabine, in his presidential address to the Royal Society, on the 30th of November, 1867, accurately described what the Meteorological Committee intended to do when he said—"The Committee are prepared to convey, free of cost, telegraphic intelligence of the existence of any serious atmospherical disturbance which may have come to their knowledge, to all ports to which it appears to them that such information would be of importance. Such a telegram may be, for example:—'Storm from west at Penzance and south coast.' On the receipt of such a message, the local authorities are expected to hoist a drum as a general warning, on seeing which masters of vessels or other interested persons may learn by inquiry at the local office (or by other arrangements) the precise nature of the information received, together with any additional particulars which may have been transmitted from the central office. It is clearly understood by all parties that any telegraphic message of a warning nature (like the example here mentioned) is merely meant to imply that there is a serious atmospherical disturbance existing along a certain region of coast, and consequently that there is, or may be, danger impending in other districts. The telegraphic messages, which are now limited to a notice of 'existing facts,' are obviously capable of extension hereafter, in proportion as the basis upon which sound meteorological anticipations may rest shall be enlarged; and this we may reasonably hope for, as one of the fruits of the establishment and action of the 'Land Meteorological Observatories.'"

According to the circular issued by the Board of Trade in December the following are the conditions on which these notices of serious atmospherical disturbances on the coasts or in the vicinity of the British Isles will be issued:—

They will be forwarded in each case as soon as information of the atmospherical disturbance shall have been received at the Meteorological Office, and the ports or fishing stations to which they are to be sent will be determined by the Board of Trade. When the list of places to which notices may be sent has been determined by the Board of Trade, it will rest with the Meteorological Committee, in each case of atmospheric disturbance, to send notices to all or any of those places, as the circumstances of the particular case may appear to the Meteorological Office to be advisable. When a telegraphic notice of atmospherical disturbance is received at one of the places named on the Board of Trade list, its receipt is to be made public by hoisting one of the late Admiral Fitzroy's drums, and the drum is to remain hoisted for thirty-six hours after the receipt of the telegraph message containing the notice.

One telegraphic notice implies that the drum is to remain hoisted for thirty-six hours, and no longer. Should the Meteorological Committee think it necessary that a drum should remain hoisted for more than thirty-six hours in any case, they will send messages to that effect, and continue them from day to day so long as it appears desirable, or until the storm shall have abated. If the authorities at any port or fishing station wish to receive intelligence of atmospherical disturbances, and will undertake to hoist the drum, subject to the conditions named, and subject to such regulations or directions as may from time to time be issued by the Meteorological Office, an application should be addressed to the Secretary to the Meteorological Committee, 2, Parliament-street, Westminster, S.W., in order that the necessary steps may be taken to place the name of the station on the Board of Trade list, and to provide the flagstaff and drum.

It is to be understood that where the place or station can pay for a flagstaff and drum they will be expected to do so, if a staff and drum are not already provided; and that where it is made to appear to the Board of Trade that no staff and drum are provided, and that the place is too poor to bear the expense, then the cost will be defrayed by the Meteorological Office, with the sanction of the Board of Trade. But in all cases, whether the first cost of the flagstaff and drum are or are not borne by the local authorities, the local authorities must undertake to bear all subsequent charges connected with the hoisting of the signal, and the maintenance of the signal apparatus. The only subsequent expense that will be defrayed by the Meteorological Office will be the charge for transmission of the notices of atmospherical disturbances.

It thus appears that the signal cone and lamps employed by Admiral Fitzroy are to be dispensed with. We are of opinion that the "cone point up" and the "cone point down" should have been the signals resumed in preference to the drum, and we should think that they must be adopted eventually unless something equally simple will answer the purpose better. When only a few hours' warning can be given towards night time, as must occur occasionally, the lamps would be useful as night signals, at least at the most frequented and exposed ports; on this account they should not be withdrawn where the local authorities are disposed to incur the expense of using them. We consider the present arrangement as temporary, and an easily available means for the Committee to furnish to the maritime community without unnecessary delay notice of weather likely to affect navigation.

The coast guard are to check these warnings by observation, and their Controller General has been expressly informed by Mr. Gray, the Assistant Secretary to the Board of Trade, that although the Meteorological Committee have, to a certain extent, adopted one of Admiral Fitzroy's signals (the drum), they have only done so as a temporary measure; and the signal, when now hoisted under the direction of the Committee, has a far more limited signification than the signals hoisted by the late Admiral Fitzroy.

Admiral Fitzroy's signals professed to give a warning of the direction, as well as the force, of an approaching storm, whilst the signal drum now to be hoisted is only intended to convey information that there is an atmospherical disturbance somewhere which possibly may reach the place where the signal is hoisted, and the knowledge of which is likely to be of use to the mariners and fishermen of that part of the coast. As the new system only announces existing facts in an extremely indefinite way, without committing itself to any consequent results, it appears rather difficult to imagine how it can be checked or where the necessity for a check lies. The truth is—and this is especially apparent in this correspondence—that the affair is without a guiding and a directing mind. Several heads are in the work, and the code of action is not yet accurately drawn up. No one can regret that it is so, because it certainly is not desirable that the system should rely upon one person's experience. Possibly we may arrive at such general aptitude that every man may be his own weather prophet.

THE GOVERNMENT AND THE TELEGRAPH.

A QUESTION at the present moment occupying the minds of a great many—particularly those in any way connected with the various telegraph companies—is that of the Government and the telegraph. The subject has now for some time been discussed, and the action of the Government surmised; but beyond the usual notice from the Parliamentary agents, and a few words from Mr. Ward Hunt that the bill would soon be placed before the House, we have no information of the bill nor knowledge of its details. Papers have been read upon the subject, pamphlets and articles written, some in favour of and some against the Government, but the fact remains the same: it is the intention of the Government to assume the control of our existing private telegraph systems, and to convert them into one service under State management. To enable them to do so a bill will shortly be brought before Parliament giving the necessary details. Into this bill we do not at present wish to enter, but in the meantime will confine our attention to the question, Will this transfer benefit the public and the State?

First, let us glance at the position of some of the telegraph companies, and note some of the anomalies of the existing system. Our present telegraph service is conducted by several telegraph companies, who formerly, one and all, opposed each other—in good railway style—reduced their rates, and so on, until seeing their folly, they mutually agreed to a revision of tariff, charging similar amounts to the same places, and agreeing not to trespass on each other's strongholds, the consequence being that whatever company we chose to send a message by to any place, the charge would be the same, although perhaps the speed by one line would be greater than by the other. At the present time there are very few important towns in the United Kingdom that are not served by more than one company, who probably have each more than one station in the same town, the quantity of offices depending of course upon the size of the town.

The various companies now consist of the Electric and International, the Submarine, British and Irish Magnetic, United Kingdom, and the London District Telegraph Companies, the two former possessing numerous cables to the Continent, and through these all our continental traffic pass. In addition to the above, we find several private railway telegraphs, the principal of which are the South-Eastern and the London, Chatham, and Dover, kept exclusively under their own management. With the exception of the districts supplied by the two last-mentioned companies, there is hardly a place (except in Ireland) served by the many companies without it also being served by the old-established company, the Electric and International. We may, therefore, take it as a general fact that north of London every important town has more than one telegraphic service, but under different management. Presuming we want to send a message, say, from the north—Edinburgh to Ramsgate, or any place on the Chatham and Dover or South-Eastern lines, we have the choice of sending it by two companies as far as London, where their responsibility ceases; it there (the message being paid through rates) is sent out like an ordinary received message, and delivered to the proper railway company, signed for, and is sent forward again in the same manner as before; if anything goes wrong, it is usually the case of the "two stools," and the claimant gets nothing. There is one important point for telegraph business, and that is the Stock Exchange,

Digitized by Google

which is supplied with offices inside and stations outside, belonging to the various companies, in quantities. One naturally remarks, What a waste of money, rent, furniture, and staff, when one office would do all that is required; and so it is throughout the kingdom. How many places are there not with rival offices next door to each other? What do the public gain? Nay, do they not lose in having to pay extra for messages to allow of the extra offices being kept up? In London, we have a company called the London and Provincial Telegraph, who will take messages for anywhere, the company being originally formed for supplying London and the suburbs. They do so at the rate of one shilling per message (it was formerly sixpence). Close to many of the stations the Electric Company will send messages for sixpence!

Now, presuming the whole system were purchased by the Government, and worked by them under one management, what would be the result? The first would, as a result of one management, be the retirement of the chairmen and directors of the various companies. And it strikes us most forcibly that the principal opposition we have heard to the scheme has been from this quarter—witness certain rather strong language used at a late half-yearly meeting—for will not their occupation be gone? As a natural result, the expensive administrative staff maintained by each company will not be required, the multiplicity of stations can be dispensed with, and stations placed in the various towns at points where they are actually wanted, where they will be of the greatest use. The ultimate point to arrive at in this transfer will be the serving the public with telegraph stations wherever there are postal stations. This will, we have no hesitation in saying, be the result of establishing the two systems under one management. And will not the public gain thereby? The principal advantages accruing to the public may be stated, that messages will everywhere be under one control, that in consequence of the existing rivalry (necessitating a needless number of offices) being done away with, the expense of messages will be less; that there being more wires available to the same place by this fusion the speed will be accelerated; that the system of telegraphy will, by reason of its cheapness, be extended generally to all classes.

It has been contended that the Government will spoil what is now well managed. We have no particular fault to find with the present management of the telegraph companies, but we most certainly think that an administration which has brought our postal system to so high a state of excellence, is thoroughly competent to undertake and successfully carry out the scheme of uniting the whole together, especially when we consider that in the present change we should only lose the services of the Board, whilst the staff would remain as they are now. If they have been instrumental in efficiently serving the company, surely they will also be so in serving the Government. If the present expensive system of telegraphy can be worked so well as to produce to the shareholders a return of handsome dividends, why should it not when worked under one management at a greatly reduced scale of message charges, produce some revenue to the Government? Almost invariably the decrease in the tariff has produced a very large increase in the number of messages. Were the Government to take the control, the messages might then be so reduced as to bring it within the reach of many, who now, except in cases of the direst necessity, cannot use it from its expense. There are numerous arguments in favour of the scheme, and but few against it that have any reason in them. For ourselves, we are convinced of the incalculable advantage such a scheme will be not only to each and all of us, but to the State, and we trust to see the time when every village, town, or place provided with a post-office will be equally provided with a telegraph office. Our space will not admit of our entering into any of the details or principal features of the scheme. We are content for the present to express our approval of the objects of the bill, leaving the discussion of the question of details to a future time.

PHOTOGRAPHY.

THE CHEMICAL ACTION OF LIGHT—REGISTRATION OF THE CHEMICAL INTENSITY OF THE RAYS OF THE SUN—ARTIFICIAL LIGHTS IN PHOTOGRAPHY—A NOVEL ACTINOMETER.

LAST Saturday afternoon, Professor Roscoe, F.R.S., of Manchester, performed at the Royal Institution some good experiments illustrating the action of the chemical rays of light upon some descriptions of common matter. In the first experiment he employed a bulb of very thin glass, about the size of a hen's egg, which had been filled in the dark or in yellow light with a mixture of pure hydrogen and chlorine gases. The gases were produced by the decomposition of hydrochloric acid by the voltaic current, the first portions of gas coming over being allowed to escape, but the remainder being passed into a string of excessively thin glass bulbs connected by fine tubes. After the bulbs were thus filled the connecting tubes were carefully sealed and separated in the middle by the aid of as little heat as possible from a Bunsen's burner. Although great care may be taken, a few of the bulbs are liable to explode during the sealing process. The bulbs, when filled with the mixed gases, are then kept from light in a box, and may thus be preserved for any length of time, as long as no chemical rays of light can get at them. A bulb thus prepared was placed in a four-sided lantern. Of these sides one was made of red and the other of blue glass, and the room was darkened at the time of the insertion of the bulb, and also during the whole of the experiment. Professor Roscoe having covered up with a cloth all the sides of the lantern except the one composed of red glass, placed a long stoppered glass jar filled with nitric oxide and bisulphide of carbon vapour in front of the exposed side of the lantern, and on applying a burning match to the mouth of the long bottle a brilliant flash of pale blue light, rich in chemical rays, was the result. But as red glass absorbs such rays, none could get through to the glass bulb in the lantern, which consequently remained uninjured. A second jar of the mixed vapours was next fired in front of the blue glass side of the lantern, and as blue glass transmits the chemical rays, the union of the hydrogen and chlorine was the result, and the bulb burst with a loud explosion.

A pure yet very bright yellow light is often desired by photographers when working with very sensitive chemicals. In his next experiment, Professor Roscoe used a very pure yellow light, produced in a very simple and inexpensive manner. Two little pieces of platinum wire, each ending in a little loop only about one-sixth of an inch in diameter, were pushed into the flame of a Bunsen's burner, and held there by a suitable stand. The Bunsen's flame contained so much common air that it gave no light of its own whilst burning. A small lump of carbonate of soda having been placed in each of the little platinum loops, the latter were pushed into the colourless flame, where the soda fused, and at once caused the flame to throw out an intensely yellow light. A fused drop of carbonate of soda will last in such a flame for a considerable time, hanging in the platinum loop like a pellucid drop of water. Such is one of the best means of producing a pure monochromatic flame.

The lecturer having made these arrangements, then exhibited the development of a photograph to the audience in a very neat manner. A magic lantern, with an oxy-calcium burner, was made to throw a disc of light upon the screen, which disc was made red in colour by the insertion of a sheet of red glass immediately in front of the condenser of the lantern. Professor Roscoe had the gas-lights of the Institution carefully turned down, then by yellow light he coated a glass plate with collodion, and excited it in the nitrate bath. Then a negative was placed in front of the prepared wet plate, and kept from touching it by means of a few folds of blotting paper at each side, between the two plates, which were thus separated to the extent of a small fraction of an inch. The negative was next exposed for five seconds to the light of a flame of common gas, placed about twelve inches off. A developer was then applied to the prepared plate, which with great speed was at once placed in the lantern, in front of the red glass. At first nothing appeared, but in a few seconds the picture was seen gradually growing and intensifying upon the screen. Professor Roscoe stated that nothing is known of the nature of the invisible image formed upon the film by light, but if he were to "read up" recent investigations on the subject he might discover that more is known of what light does in the film than he at present supposes to be the fact.

Except an intensely brilliant yellow light be desired upon the plate, there is no necessity to employ a monochromatic flame. The lights in the roof of the Institution might have been left alight, turned down just enough to permit the lecturer to work with ease, and there would not have been the slightest danger of fogging or failure from this cause. The chemical action of light diminishes as "the square of the distance," and at a few yards from the flame of a candle or common gas, any photographer may work with impunity, though certainly it requires some courage to do so for the first time, with the knowledge that such light acts vigorously upon his plates at small distances.

For about a year the daily registration of the chemical intensity of daylight was performed by Dr. Balfour Stewart, F.R.S., superintendent of the observatory of the British Association at Kew. The method of registration was designed by Professor Roscoe. By his plan, a strip of standard photographic paper, very carefully prepared, was exposed for a measured time to the rays of the sun, and then the depth of colour it thereby acquired was compared with a permanent strip of similar photographic paper, tinted throughout its length to various depths by the action of light. The plan is obviously imperfect, but is the best at present known, for the registration of variations in the chemical activity of light is anything but an easy task. Observations were thus made three or four times a day at Kew by Mr. Baker, one of the assistants, and a few facts as to the variations in the chemical action of light at different times of the day and year were thus obtained. But as changes in chemical activity vary with every passing cloud, as well as from other causes, three or four observations a day gave a very meagre array of facts, and the work has been discontinued. It is, however, in contemplation to renew the registration once more in all the observatories now partly under the control of the Meteorological Department of the Board of Trade, if continuous self-registering apparatus can be made, and such apparatus Professor Roscoe is said now to be devising.

An instrument which will show every passing change in the chemical action of daylight, in the same tangible way that a barometer shows changes in atmospheric pressure, would be a great boon both to photographers and meteorologists. A plan of this kind has just been mooted by Mr. W. H. Harrison, whereby a magnetic needle will swing to and fro with the changes in the chemical activity of daylight, and the design will shortly be tried in practice. The principle is readily explained. Parallel rays of light from the sky or sun are freed as much as possible from the heat rays of the spectrum, by passing through one glass trough filled with solution of alum and a second trough filled with ammonio-sulphate of copper. The parallel rays are then received on the face of a common large glass lens, which condenses them upon one end of a thermo-electric pile, which pile is placed in the centre of a closed box, a "chamber of constant temperature." A galvanometer is attached in the usual way, to register any changes in the intensity of the chemical rays thus falling upon one end of the pile. The intensity of light from the northern sky is that which photographers most want to be able to measure, for the direct light of the sun is never used in portraiture, and not always in landscape photography. The chief objection to the mode of measurement just stated is that it is difficult to fix a value at different times upon the deflections of the galvanometer, for so many circumstances tend to set up changes in the magnetism of the needle. Yet one step will be accomplished when a needle is made to move with the changes in the chemical activity of light, and when that is done it will be the business of the electrician to reduce the deflections to a constant value. Such a task is not insurmountable, as proved by the elegant devices invented by electricians to test for faults in submarine cables, and to secure constant and reliable results.

NOTES ON RECENT SCIENTIFIC DISCOVERIES AND THEIR PRACTICAL APPLICATIONS.

A NEW METHOD OF MAKING WHITE LEAD—A BLACK ANILINE DYE FOR WOOLLEN CLOTH—A MODE OF TESTING STEAM BOILERS—THE SEPARATION OF OLEINE FROM STEARINE, &C.—LOUVEL'S SYSTEM OF STORING CORN AND FLOUR.

SEVERAL processes have been devised for producing white lead in less time than is required by the old Dutch process still followed in the manufacture of the best article. They have resulted, however, for the most part, in comparative failures. The pigment produced by precipitation has in general a crystalline character which seriously interferes with its covering property, and thus deteriorates its value. A process has recently been devised by M. A. Girard which is perhaps superior to most of the new modes of manufacturing white lead. Metallic lead is, in the first place, granulated. It is then placed in a barrel (which must be made of beech or hornbeam wood, not oak), with one-fourth its weight of pure water. The barrel is placed on an axis, so that it can be made to rotate at about thirty or forty turns a minute, and arrangements are made so that a current of air can be forced through at the same time. After rotating for about two hours almost all the lead will be found oxidised; and now a current of carbonic acid is substituted for the air, and the rotation continued for four or five hours longer. After this time nearly all the lead will be found converted into the hydrated carbonate, the true white lead, which can be separated by decantation from any of the metal unacted on, and washed and dried. The product so made, we are inclined to believe, will be as good as that produced by the old process.

We recently gave a process for a black aniline marking ink which attracted some attention. To-day we find a process for dyeing wool black by means of an aniline compound. The yarn or cloth is first submitted for an hour to a bath composed of 1 litre (two pints) of water; 5 grammes (75grs.) of bichromate of potash; 3 grammes (46grs.) of sulphate of copper, and 2 grammes (31grs.) of sulphuric acid. The bath must be used at nearly a boiling heat. After this the cloth or yarns are well washed, and then plunged in a solution of oxalate of aniline of 1 or 2deg. Beaumé (sp. gr. 1·007 to 1·014). They are said thus to be dyed of a beautiful solid black, which will have the advantage of resisting all the agents that usually discharge or alter the colour of black cloth. This process, if it answers well, and, since it is the invention of M. Persoz, we are bound to regard it with favour, will be a great gain to the dyers of black cloth. Some extra brilliancy, it is said, may be given by rinsing the cloth in a bath of cream of tartar solution, with a little sulphuric acid, washing again, and soaping.

Steam boilers are weakened by long working, and the owners are uncertain as to what pressure they can resist. Few are possessed of a hydraulic pump by which they can be tested; but Mr. Robinson, an American engineer, gives a method by which a boiler can be tested by any working engineer. He completely fills the boiler with water up to the throttle and safety valves, and makes everything tight, leaving only the pressure gauge open. He then puts a fire under; the water slowly expands, and the pressure is of course shown on the gauge. If there is a weak place, it will give way long before the water reaches the boiling temperature, and no sudden or dangerous explosion will happen. If no rupture take place, the pressure shown on the gauge will teach up to what point the boiler may be safely worked. Engineers will, no doubt, give us their opinion of this mode of testing an old boiler.

Bourgougnon gives a process by which he says oleine may be easily separated from the solid fatty acids without the liberation of any oleic acid, as usually happens in the processes ordinarily followed. We give it for what it may be worth, without expressing any opinion on its merits. The tallow is first melted with an equal weight of water, and the mixture is warmed with 10 per cent. of strong ammonia. In this way a thick emulsion is obtained, which is heated to a boiling temperature, to get rid of the ammonia and drive off the water. The residue is then submitted to pressure, by which the oleine is perfectly separated, and the solid acids left harder than usual.

We mentioned some months ago Dr. Louvel's system of preserving corn and flour in air-tight cylinders. Two of these cylinders were placed in a boiler house at the French Exposition, and remained there four months. At the bottom of one of these cylinders was put some mildewed and decomposing lentils and above twenty sacks of wet wheat. In the other was put some good fresh flour, with some that had been three years in store at Vincennes, and had also been to London and back, and was necessarily not in good condition. These cylinders were opened a short time ago and the contents examined. The wheat in the one was found dry and in good condition, the mildew not having spread from the decaying lentils. The flour was also in an excellent state. Dr. Louvel mentions that he has contrived some cheaper utensils, but we fear the difficulty of getting and maintaining a vacuum in large vessels will be an obstacle to the general application of his system, valuable as it undoubtedly is.

Parliamentary Notes.

THE Banda and Kirwee prize money still continues to give trouble. Only last Friday, in the House of Commons, Mr. Neville-Grenville was obliged to ask the Secretary of State for India why the officers and men of the Royal Regiment of Artillery, who served at the capture of Banda and Kirwee in 1858, had not yet received any portion of their shares of the prize money granted them by royal warrant, although the rest of the troops, both of Her Majesty, and the late East India Company, had received a first and second instalment.

Sir S. Northcote said the reason was that the prize roll of the troops referred to in the question of the hon. member had not been received in this country by the Prize Committee, although it had twice lately been expressly called for. A satisfactory reason, perhaps, to the Secretary of State for India, but, certainly, far from satisfactory to the captors of Banda and Kirwee. It is a shame that the necessity for Mr. Neville-Grenville's question has been allowed to arise.

On Monday, Mr. Ewart moved for leave to bring in a bill to introduce into this country the metric system of weights and measures. As Mr. Cave offered no opposition to the motion, leave was given, and the bill was subsequently brought in and read a first time.

At the same sitting of the House the question of the unsatisfactory condition of telegraphic communication with India was brought before the members by Captain Vivian. This led to an apologetic defence by Sir S. Northcote, who, in reply to the noble captain, admitted that the telegraphic communication between this country and India was certainly not all that could be desired, but he did not think it could be described as very unsatisfactory. He believed the average rates of transmission of messages from India during the first twenty days of February was, viâ Russia, three days and nine hours; viâ Turkey, three days and eleven hours; and that in the last week of February it was, viâ Russia, two days and twenty-two hours; while individual messages had occasionally been received on the day of despatch, both viâ Russia and Turkey, and frequently on the day following the day of despatch. He might observe, with regard to the existing line of communication, that steps were being taken which would, he hoped, improve those lines. Turkey and England had recently been admitted to the telegraphic convention of Paris, and the effect of this would be that greater rapidity of communication would be secured. Moreover, the concession which had recently been obtained by Messrs. Siemens and Company, for a line by Russia and Persia, would probably improve the communication by that route; but, nevertheless, it would be a great advantage to this country if another line of communication could be obtained viâ the Red Sea. This had received the attention of the Council of India, and also of the Imperial Government, neither of whom thought it would be right in the present state of submarine telegraphy to burden the revenues by giving any guarantee or subsidy. They would be glad to give any assistance in the way of a survey or otherwise to a private company which should construct the line, but no company had at present been found willing to undertake the matter. It was thought desirable when the Abyssinian expedition was projected, to construct a line to Massowah or Annesley Bay, or whatever port would be fixed upon as the port of debarcation; but this was abandoned when it was found that the line could not be laid in time to be of much practical use. He had received on the previous day a very full private letter from Sir Robert Napier, who said that the only way in which telegraphic communication could be satisfactorily opened would be by a submarine cable down the Red Sea, which he recommended as being, in his opinion, desirable on the ground that it would be so much on the road to India. Sir Robert further said that such a line would be of use to the expedition, if it were prolonged, but he said—and this was a most satisfactory point in his letter—he had the utmost confidence that the expedition would be completed in the present season. Therefore, Sir Robert Napier did not press the matter in connection with the expedition, but chiefly as offering the advantage of a direct Red Sea line connecting this country with India; and as he (Sir S. Northcote) had already said, her Majesty's Government would not be justified in encouraging such line by guarantee or subsidy, but would be very glad to see it established by private enterprise.

The Turks, it appears, have been wanting to have a little British experience imported into the conduct of their naval affairs. So they asked us to recommend them an officer up to the work of naval organization, and we promised them one. While we are fulfilling our promise and securing it well with red tape, another naval officer steps in on his own account, and secures the post. Very uncomfortable for officer No. 1—very disappointing, too. So he rushes into Parliament, through Captain Mackinnon, from whose question and Lord Stanley's reply we gather the facts of the case. Captain Mackinnon asked if it was true that Commodore Sir William Wiseman, R.N. (naval officer No. 1), was appointed some months ago by the Admiralty to proceed to Constantinople to assist in the organization of the Turkish fleet, and if that appointment had been approved by the Secretary of State to the Turkish Government; and if it was true that this officer was not now to proceed to Turkey in consequence of another British officer (No. 2) of the Royal Navy having accepted the appointment without the sanction of the Government; and what steps the Government had taken to recall this officer, to allow Sir William Wiseman to take up the duties he was appointed to last summer.

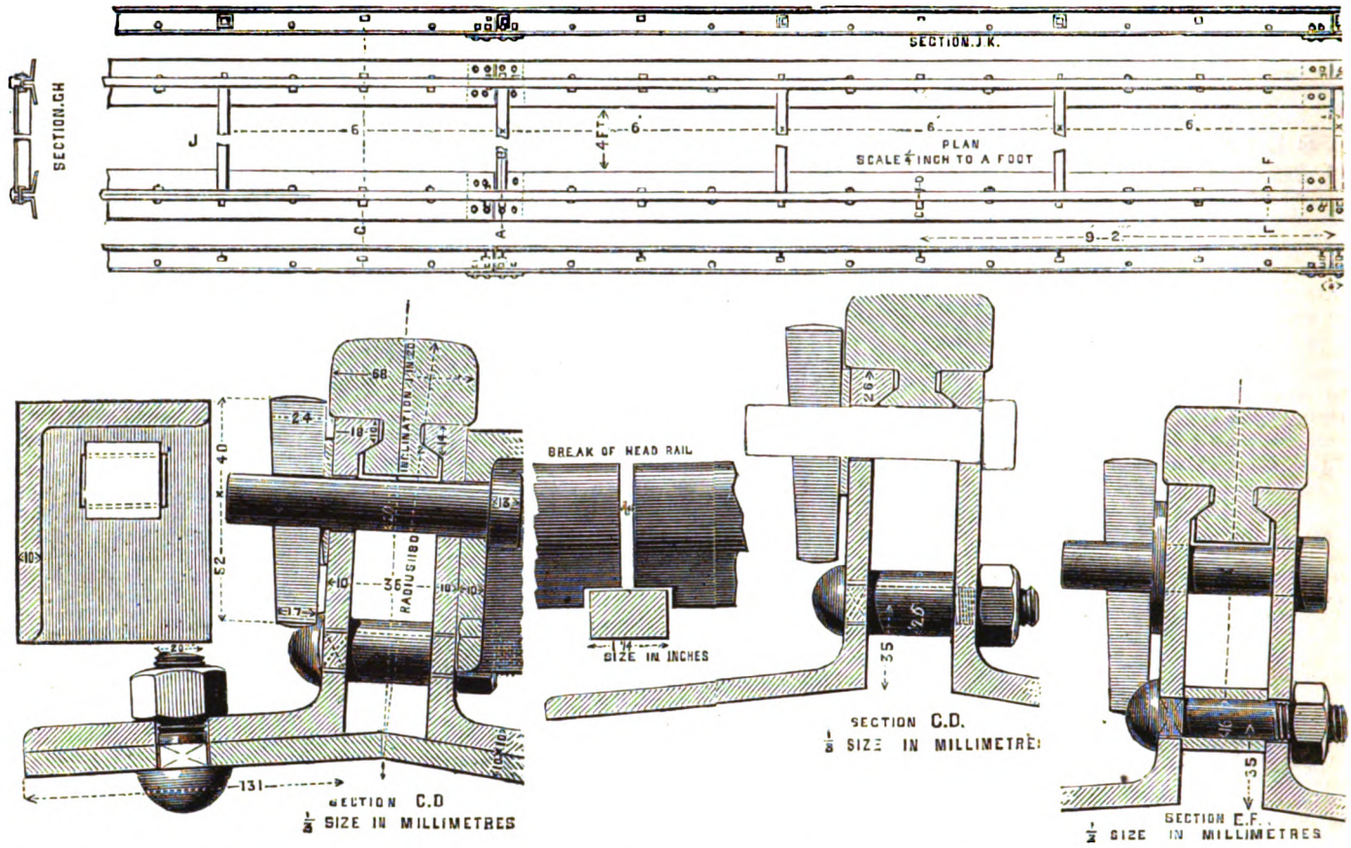
In reply, Lord Stanley stated that in May last year the Turkish Government expressed a wish that a British naval officer of rank should be selected to act as member of a council on naval affairs—a kind of Turkish Board of Admiralty—which was lately established at Constantinople. The British Government saw no objection in principle to this proposition, Turkey being at peace with all nations, and Sir William Wiseman was selected by the Admiralty for the post, but the Government thought it better that the appointment should remain in abeyance until the termination of the Cretan war. That war, though on a very reduced scale, still continued, and therefore the appointment had not been carried out. In December last it was reported at the Foreign Office that Captain Hobart, of the British navy, was about to enter the Turkish service. He (Lord Stanley) communicated with the Admiralty upon the subject, and Captain Hobart was informed that in the event of his taking service with the Porte without the consent of his own Government, he could not remain in the English navy. A letter was shortly after received from Captain Hobart, stating that he had accepted office as a member of the Turkish Admiralty Board, and offering, in consequence, to resign his commission in Her Majesty's service. That resignation had, he understood, been accepted; but no communication had been received at the Foreign Office in reference to the subject. He might add, in conclusion, that the appointment being of a civil, and not a military character, Captain Hobart did not, by accepting it, violate the laws of his country. Rather a hard case for Sir William, but there appears to be no help for it, and he must bear his disappointment as best he may. Government must look out for something for him in another direction.

A very important question has been asked by Mr. Candlish, who wished to know whether, during the present season, the Secretary of State for the Home Department intended to introduce a bill to prevent the pollution of rivers; or, if he did not intend to legislate on the whole subject, if he would introduce a bill to prevent solids being deposited in rivers.

Digitized by Google

ROCHUSSEN'S PERMANENT WAY, BRUNSWICK RAILWAY.

CONSTRUCTED BY THE HOERDER IRON AND STEEL COMPANY, WESTPHALIA.



Mr. G. Hardy was not prepared to legislate upon this question during the present session, as he did not think the inquiry had been sufficiently completed. He intended to move for the appointment of a new commission of inquiry into the subject. Unquestionably, the sooner the whole subject is inquired into and legislated upon the better; all our rivers, with, perhaps, the exception of the Thames, are nothing better than sewers, not merely from the deposit of actual sewage matter in them, but from numerous other sources of pollution. Gasworks, various manufacturing and industrial establishments, mills of all kinds, and numerous other works, discharge millions of gallons of refuse into the nearest stream, utterly regardless of the finny inhabitants, or the more serious contingency of the death of those residing on its banks.

ROCHUSSEN'S PERMANENT WAY.

IN the accompanying engraving we illustrate the permanent way laid on a length of twelve English miles of the Brunswick Railway, a portion of the main line between Cologne and Berlin, on other sections of which very similar forms of iron permanent way, also made by the Hoerder Company, have been in use for the last two years. Our engraving shows the latest development of a system deserving the most serious attention from engineers, if for no other reason, then because of the excellent results which have followed on its adoption by continental railway companies. The special features of difference between this way and forms embodying the same principles previously used, consist in the shape of the steel head-rail, which, by means of a grooved web, is securely held by corresponding ribs in the angle bars, and tightened up by bolts, passing not through but under the rail-head, and tapered cotters, no nuts and screws being used for this purpose. The great advantages secured by this arrangement are that no holes require to be made in the steel—it is well known that steel will not bear punching, while drilling is a tedious and costly operation—and, secondly, that the line can be put down with little trouble, as it is not necessary to make the holes in the web-plates correspond not only with each other but with those of the rail-head. The renewal of the rail-head is therefore easily effected, and it is possible under all circumstances to turn the head end for end when the inner side is worn, which cannot be done without making fresh bolt-holes when the bolts pass through the steel rail; the angle bars resting on the ballast offer continuous support, which is, in our opinion, essential to safety in the use of any steel rail, and are held in gauge by angle iron cross-pieces placed at intervals of 6ft. The ballast is well boxed up between the angle bars up to the level of the cross-bars. The piece over this track is very easy, although the line does not lack rigidity.

In the event of a rail breaking on this system no harm would be likely to ensue; indeed, if the head were cut up into 2ft. lengths, the track, although it would lose something in rigidity, would still be practically safe, and even though the train came on a portion of the line from which a portion of the rail had been inadvertently removed, as in the case of the Staplehurst accident, it is probable that it would still keep the track, running on the longitudinal angle bearers. In such a system as this lies the best hope of those who advocate the use of steel rails. In this way, and in this way only, it is possible to use a steel table of great hardness without the smallest risk, and the scantling of the steel is so much reduced as compared with that of an ordinary rail that its high price would not perhaps be severely felt even by impecunious railway companies. As to cost, it will suffice to state that the Hoerder Works were paid for the track all round £15 per ton, or, say, £3,000 per mile; but in England we have reason to believe that it could be supplied at a far more moderate rate, say, £12 10s. per ton. A few hundred miles of track at this rate would afford excellent times just now for some of our rolling mills. This kind of track has been extensively tested on the Continent for some years, and with very favourable results, especially on the Brunswick Railway. The dimensions will all be found on the engraving in millimetres. We may add that the system has been patented by Mr. T. A. Rochussen, of Abchurch-lane, a gentleman whose name is well known in connection with the steel industry of the Continent.

A DISCOVERY of coal on the estate of Earl Manners, near Trowbridge, is reported. Boring operations are to be commenced with the view of testing the extent of the seam.

ON THE DRYING OF STEAM BY WIRE-DRAWING, AND ON ITS LIQUEFACTION BY EXPANSIVE WORKING.*

BY W. J. MACQUORN RANKINE, C.E., LL.D., F.B.SS. L. and E.

1. Free Expansion of a Perfect Gas.—One of the fundamental facts of the science of thermodynamics is the fact ascertained by Joule, that when a perfect gas expands without performing external work, its temperature does not fall. It is only when external work is done (as in driving a piston) that a fall of temperature takes place, being caused by the disappearance of a quantity of heat equivalent to the work done.

2. Free Expansion of an Imperfect Gas.—When an imperfect gas expands without performing external work there is a small fall of temperature due to the disappearance of heat in performing internal work—that is, in overcoming cohesion. That fall of temperature has been determined for various gases at different pressures and temperatures by the experiments of Joule and Thomson; but it is a very small fraction of the fall of temperature which takes place when external work is done, as in driving a piston.

3. Free Expansion of a Saturated Vapour.—When a saturated vapour expands without performing external work (as when steam is throttled or wire-drawn), the fall of temperature is greater than in the case of an imperfect gas which is not in the state of saturation, because of the comparative greatness of the internal work done in overcoming cohesion in a saturated vapour; but still that fall is not nearly so great as when external work is done; and it is not so great as the fall of the boiling point corresponding to the diminution of pressure: the consequence of which is that dry saturated vapour by being wiredrawn becomes superheated—in other words, its temperature after the wire-drawing, although lower than the previous temperature, is higher than the boiling point corresponding to the diminished pressure.†

4. Drying of Moist Vapour by Wiredrawing.—If the vapour which is wiredrawn carries with it some liquid in the state of spray, either the whole or part of that

* From "The Engineer."

† The figure of the expansion curve for the free expansion of saturated vapour is investigated at the end of a paper of mine on "Thermodynamics" in the "Philosophical Transactions" for 1854.

Digitized by Google

quantity of heat which would otherwise superheat the wiredrawn vapour will be employed instead in evaporating that spray. The proportion borne to the whole weight of fluid discharged by the greatest weight of spray which can thus be evaporated, so as to leave the vapour dry though saturated after being wiredrawn, may be found to an approximation close enough for most practical purposes as follows:—Divide the difference between the values of the total heat of evaporation of the fluid at the pressures before and after wiredrawing respectively by the latent heat of evaporation at the higher of those two pressures.*

5. Approximate Rule for Steam.—As a roughly approximate rule for practical purposes in the case of steam:—find, by the use of tables or of a formula, the fall of the boiling point corresponding to the fall of pressure: divide that fall of temperature by 3000 for Fahrenheit's scale, or multiply it by 0·0006 for the Centigrade scale: the result will be the proportion of spray which the wiredrawing is capable of drying up in each unit of weight of steam. For example, suppose the following to be the absolute pressures before and after wiredrawing in lbs. on the square inch:—Before, 100lb. above the atmosphere, or about 115 absolute: after, the atmospheric pressure, or about 15 absolute. The corresponding boiling points are:—

Before.....	338 deg. Fah.	170 deg. Cent.
After	212 „	100 „
Fall.....	126 deg. Fah.	= 70 deg. Cent.;

and the proportion of spray per unit of weight of steam which the operation of wiredrawing is capable of drying up is

$$\frac{126}{3000} = 0{\cdot}0006 \times 70 = 0{\cdot}042,$$

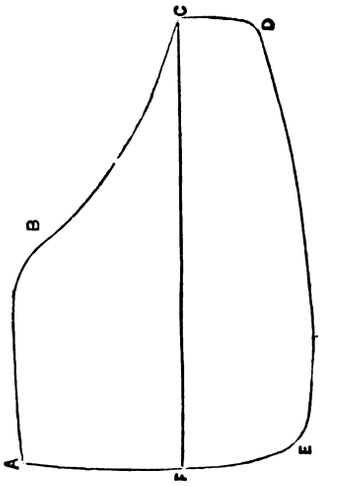
or 4·2 per cent.

6. Liquefaction of a Vapour by Expansive Working in a Non-Conducting Cylinder.—If any vapour existed whose total heat of evaporation did not vary with the boiling point, and if that vapour were employed in a state of saturation to drive a piston by its expansion in a non-conducting cylinder, the disappearance of heat during the expansive working would cause the liquefaction of a part of that vapour whose proportionate weight could be calculated exactly by dividing a quantity of heat equivalent to the work done by expansion, by the total heat of evaporation. But the total heat of evaporation of every known vapour diminishes when the boiling point is lowered; therefore, the quantity of vapour which would be liquefied by a given expansion, if the total heat of evaporation were constant, has to be diminished by subtracting from it the quantity of spray which would be dried up if the same quantity of vapour underwent the same fall of pressure by being wiredrawn without doing external work; and the remainder is the quantity of vapour actually liquefied. The following is an example for steam, the calculations being made in round numbers, as minute accuracy is unnecessary.

Pressures in pounds on the square inch: at beginning of expansion, absolute	115
At end of expansion, absolute ...	29
Rate of expansion about	3·67
Work done by the expansion per pound of steam, about	84,000ft.-lbs.
Mechanical equivalent of an unit of evaporation at pressures between the above limits, about	730,000ft.-lbs.
Proportion of steam which would be liquefied if the total heat of evaporation were constant $\frac{84{,}000}{730{,}000}$ = ...	0·115 nearly.
Subtract proportion of spray which would be dried up by wiredrawing with the same limits of pressure; fall of temperature 90· Fah. $\frac{90}{3000}$ =	0·300
Proportion of steam liquefied in a non-conducting cylinder...	0·085 nearly.

7. Peculiarities of Certain Fluids.—It thus appears that the liquefaction of a vapour through expansive working in a non-conducting cylinder is due to the difference between two quantities of heat; that which disappears in driving the piston by expansion, and that which is, so to speak, set free by the fall of the total heat of evaporation. The formulæ relating to this subject, which were published independently by Clausius and myself in 1850,* show that for every fluid there is a temperature at which those two quantities become equal; so that it is only below that temperature that vapour is liquefied by expansive working; while above it expansive working as well as wiredrawing is accompanied by superheatiug, owing to the first of the two quantities of heat becoming less than the second. It was for some time supposed that the temperature at which liquefaction by expansive working disappears was for all known fluids high above all temperatures which commonly occur in practice; and such is, indeed, the case for steam; but Mr. G. A. Hirn afterwards showed that there are some fluids for which this temperature is comparatively low, and that amongst them is ether.

8. Approximate Rule for the Liquefaction of Steam Working Expansively in a Non-Conducting Cylinder.—The exact formulæ for the liquefaction of vapours through expansive working are too complex for ordinary use in practice; but by computing several different cases in detail I have found that the following very simple rule (now, I believe, first published) is sufficiently near the truth for all practical purposes. In the figure let A B C D E



represent the indicator-diagram of a steam engine. Through the point C, corresponding to the end of the expansion, draw a straight line of uniform pressure C F. Calculate the quantity of work represented by the part A B C F of the diagram, which lies above the line of final pressure C F. Then the weight of steam liquefied will be approximately one pound for every 1,000,000ft.-lb. of work represented by A B C F, or one kilogramme for every 300,000 kilogrammetres of work represented by A B C F. If the work represented by A B C F in a given time be reduced to indicated horse-power the above rule is equivalent to 2lb.= 0·9 kilogramme of steam liquefied per hour for each indicated horse-power represented by the part of the diagram above the line of final pressure. For example, let the initial absolute pressure be 60lb. on the square inch, and the rate of expansion 4; so that for ordinary practical purposes it is sufficiently accurate to take, for the final absolute pressure, 15lb. on the square inch, and for the mean excess of the absolute pressure during the stroke above the final pressure (represented in the diagram by the mean height of the line A B F above the line C F.)

$$\frac{60 \times \text{hyp. log. } 4}{4} = 60 \times 0{\cdot}3466 = 20{\cdot}8\text{lb.}$$

on the square inch nearly. Let the area of the piston be 800 square inches, and its mean velocity 250ft. per minute. Then the work per minute corresponding to the part A B C F of the diagram will be

$8{\cdot}20 \times 800 \times 250 = 4{,}160{,}000$ft.-lbs. per minute; so that the rate of liquefaction of the steam in a non-conducting cylinder, as found by the first form of the rule, will be 4·16lb. per minute, or nearly 250lb. per hour. The quantity of work per minute calculated above is equivalent to 126 indicated horse-power which gives, by the second form of the rule, 252lb. of water condensed per hour.

9. Effect of Spray in the Steam when Admitted.—The preceding calculations are based on the supposition that the steam when admitted, though saturated, is dry. Should there be liquid spray in the steam when admitted, the heat given out by that spray as the temperature falls during the expansion will to a certain extent diminish the quantity of steam liquefied. The theory of this has been fully investigated by Clausius and Zeuner. In such cases as those to which the present communication refers, it may be sufficient to state, as a rough approximation, that the presence of one per cent. of spray in the steam when first admitted, diminishes the quantity of steam subsequently liquefied during the expansion by about one-eightieth part of its amount. For example, the presence of one per cent. of spray in the steam when admitted, in the case computed in article 8, would diminish the subsequent additional liquefaction per hour by about 3lb. A large proportion of spray would be required in order to make an effect of this kind sensible.

10. Effect of a Conducting Cylinder.—If a conducting cylinder is unclothed, it of course causes part of the steam to become liquid simply by carrying off heat to the air outside, and this effect is increased indirectly by the liquefaction through expansive working; because moist steam is a better conductor of heat than dry steam, and parts with its heat more rapidly to any neighbouring conducting substance which is at a lower temperature. This effect may be prevented by clothing the cylinder with a sufficient thickness of a substance which resists the conduction of heat. But there are other effects of the conducting power of the cylinder, when not steam-jacketed, which are not prevented by a non-conducting clothing. One of these is, that the metal of the cylinder, assuming temperatures intermediate between those of the steam at the beginning and at the end of the expansion, abstracts heat from the steam during its admission, and during the early part of the expansion, and gives heat back to the steam during the later part of this expansion; and that, consequently, the liquefaction due to the expansive working does not take place wholly during the expansion, but partly during the admission of the steam. This effect is shown by the flattening of the expansive curve B C in the indicator diagram; and also by the expenditure of a greater weight of steam than that corresponding to the volume at the pressure of admission as indicated by the length of the line A B; and it is unfavourable to economy; for the proportion borne by that additional expenditure of steam to the whole expenditure is much greater than the proportionate increase of work due to the flattening of the expansion curve. It is evident, indeed, from ordinary indicator diagrams, that the quantity of steam liquefied during the early part of the stroke is often greater than the quantity due to the expansive working, and that a partial re-evaporation takes place towards the end of the stroke. Another effect of the conducting power of an unjacketed cylinder is, that if there is liquid water present in that cylinder at the end of the stroke, part of that water may, by abstracting heat from the cylinder, be distilled away into the condenser, thus lowering the temperature of the metal of the cylinder below the final temperature of the expansion; so that an additional quantity of steam is condensed during its admission in raising the temperature of the metal again, and a certain quantity of heat passes at every stroke from the boiler through the cylinder to the condenser without contributing to the performance of work. Those effects of the conducting power of the cylinder in combination with the spontaneous liquefaction of steam due to expansive working are very fully discussed in two papers (the first by myself, the second by Mr. James Brownlee) in the "Transactions" of the Institution of Engineers in Scotland for 1861-2.

11. Use of a Steam-Jacket, and of Moderate Superheating.—The liquefaction of steam by expansive working is not of itself a cause of waste of heat or power; and in a non-conducting cylinder (if such a thing were possible) it would have no

* The following is the algebraical investigation of the rules given in the text:—Let the latent heat of evaporation of the fluid be denoted, before being wiredrawn by L, and after having been wiredrawn by L^1; let c be the specific heat of the liquid, t and t^1 the boiling points corresponding to the pressures before and after being wiredrawn respectively, and s the fraction of the whole weight of fluid discharged, which is in the state of spray before wiredrawing, and whose value is supposed to be so adjusted that the vapour, after being wiredrawn, though still saturated, is dry. Then, from the condition that no external work is done, there follows this equation:—

$$L^1 = c\,(t - t^1) + (1 \ldots s)\,L; \quad \ldots\ldots \quad (1)$$

and, consequently,

$$s = \frac{L - L^1 + c\,(t - t^1)}{L}; \quad \ldots\ldots \quad (2)$$

In the case of steam, we have $L - L^1 + c\,(t - t^1) = 0{\cdot}3\,(t - t^1)$ ordinary thermal units nearly: and for a rough approximation, we may take L = 900 British thermal units or 500 French thermal units; consequently, for steam, we have nearly

$$s = \frac{t - t^1 \text{ Fah.}}{3000} = 0{\cdot}0006\,(t - t^1) \text{ Cent.} \quad \ldots \quad (3)$$

* "Transactions of the Royal Society of Edinburgh" for 1850, vol. xx.; Poggendorff's Annalen, 1850: see also "A Manual of the Steam Engine and other Prime Movers," pp. 395-6.

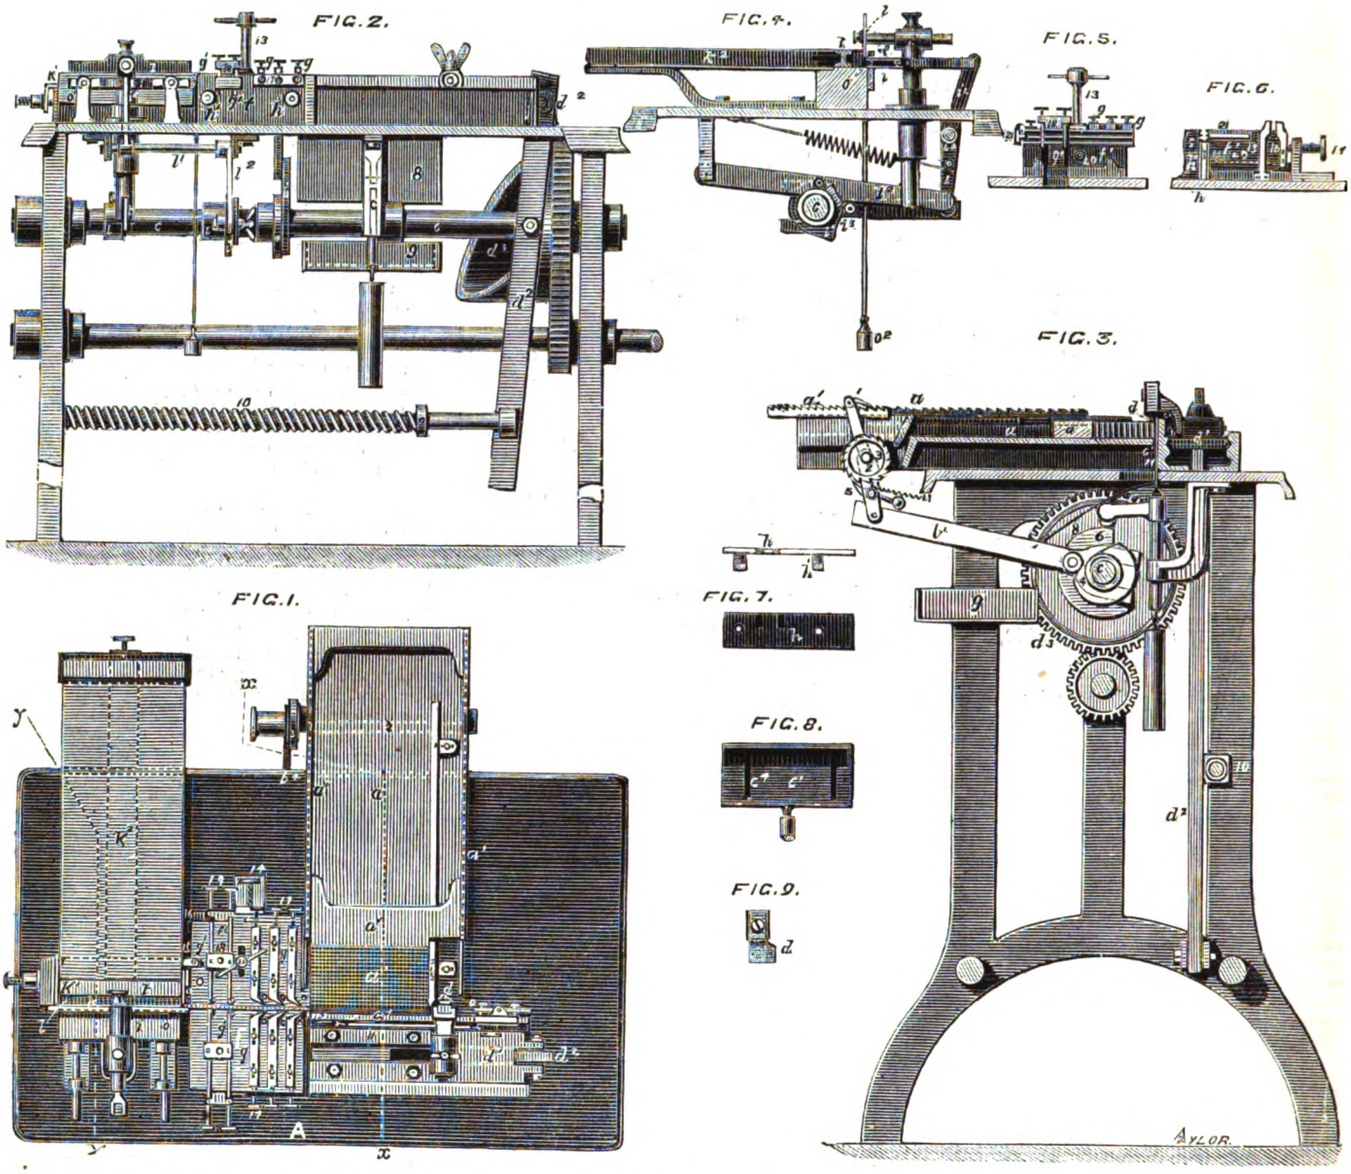
MACHINE FOR DRESSING TYPE.

BY MR. P. WELCH.



effect on the economy of the engine. When work is done by expansion, heat must necessarily disappear; and the disappearance of that heat must necessarily take effect in producing fall of temperature, or liquefaction, or both. The bad economy of engines in which much steam is liquefied in the cylinder is owing to the fact that the presence of liquid water amongst steam increases its conducting power, and makes it give out heat rapidly to the metal of the cylinder, as explained in the preceding article. A steam-jacket supplied from the boiler prevents the liquefaction of the steam which works expansively in the cylinder, through the liquefaction of an approximately equal quantity in the jacket: the quantity of steam liquefied is about the same; but the liquid water, instead of being formed in the cylinder, where it is mischievous, is formed in the jacket, where it does no harm; and instead of going to the condenser, and carrying off heat, it is returned to the boiler. The first effect of a moderate amount of superheating is the same with that of a jacket; the superheated steam on entering the cylinder raises the temperature of the metal to an extent sufficient to prevent the formation of liquid water, at all events in such a quantity as would be sensibly prejudicial to economy.

12. Bearing of the Preceding Principles upon Questions as to the Priming of Boilers.—From what has been stated it may be concluded, on the one hand, that the discharge of dry steam from a safety valve or other opening in a boiler does not conclusively prove that the steam inside the boiler is dry, but only that the proportion of spray mingled with it is not greater than can be dried up by the wire-drawing; and, on the other hand, that the discharge of liquid water from the cylinder of a steam-engine affords no proof whatsoever that the boiler primes.

Glasgow University, February 17.

MACHINE FOR DRESSING TYPE.

THE process of dressing printing type, although quickly performed by those engaged in the work, from mechanical habit, is nevertheless one that is open to the improvement machinery always affords over any manual operation. In our engraving we represent a type-dressing machine which has been invented and recently patented in England by Mr. Patrick Welch, of New York. Fig. 1 is a plan of the machine. Fig. 2 is an elevation at the side A of fig. 1, the legs of the frame being broken off. Fig. 3 is a vertical cross section at the line x x, fig. 1. Fig. 4 is a partial section at the line y y. Fig. 5 is an elevation of the face of one of the cutter blocks. Fig. 6 is a side view of the cutter blocks and gauge for determining the thickness to which the types are rubbed or dressed. Fig. 7 is a plan and elevation of the bridge over which the types pass when between the cutters. Fig. 8 is an elevation of the slide that delivers the slices or rules that keep the lines of type separate. Fig. 9 is a face view of the pusher, its axis being shown by dotted lines. The types are set up in line and placed in column in a galley a, and between the lines metal rules or slices are introduced, The column of type is moved up by a sliding frame a^1 at the proper time, as one line at a time is conveyed away and passed through the cutters to dress it. The frame a^1 is operated on by pawls 1 1, on arms from a cross shaft 2; 3 is a ratchet wheel that is loose on shaft 2, but clamped by friction plates on its side, and b^1 is a bar vibrated by the cam 4 on the main shaft c, and acts by a pawl 5 on the wheel 3 to cause the pawls 1 1 to move the column of type forward into the machine the width of one line.

The lines of types only being carried off endwise through the cutters it is necessary to dispose of the rules between the respective lines; to effect this a recess is formed in the sliding plate c^1 into which the rule or slice passes as the line of types comes against the face of that plate c^1. After the line of types has been carried off, this sliding plate c^1 is carried down below the bottom of the galley a by the weight c^2 and cam 6 on c, and stationary inclines 7 acting through slots c^4 (figs. 3 and 8) in c^1 throw the slice out of the recess upon an incline 8, down which it slides into a receptacle 9. In order to move the lines of types along, a pusher d is mounted on a slide d^1, and moved at the proper time by the lever d^2, cam d^3, and spring 10. The pusher is a movable piece of metal that may be changed to accommodate thick or thin type, and the device that connects the pusher and slide is a rock shaft with a screw clamp, so that the edge of the pusher can be set at an inclination to accommodate the inclination there may be in the type at the end of the line resulting from the projecting burrs at the bases of the letters, keeping the bodies of the types slightly apart at the letter ends.

The follower e is drawn in behind the pusher by the the spring 11, and by its thin ends holds up the next rule and line of types. A small friction spring at 12 holds up the last type in the line of types as the pusher leaves it on going back to allow another line of types to come up to the face of the sliding plate c^1. The blocks f and f^1 carry the cutters; the block f is stationary, and the block f^1 movable nearer to or farther from the block f, according to the width of the lines of type to be dressed. The screw 13, in a slot in the block f^1, is employed to hold the same

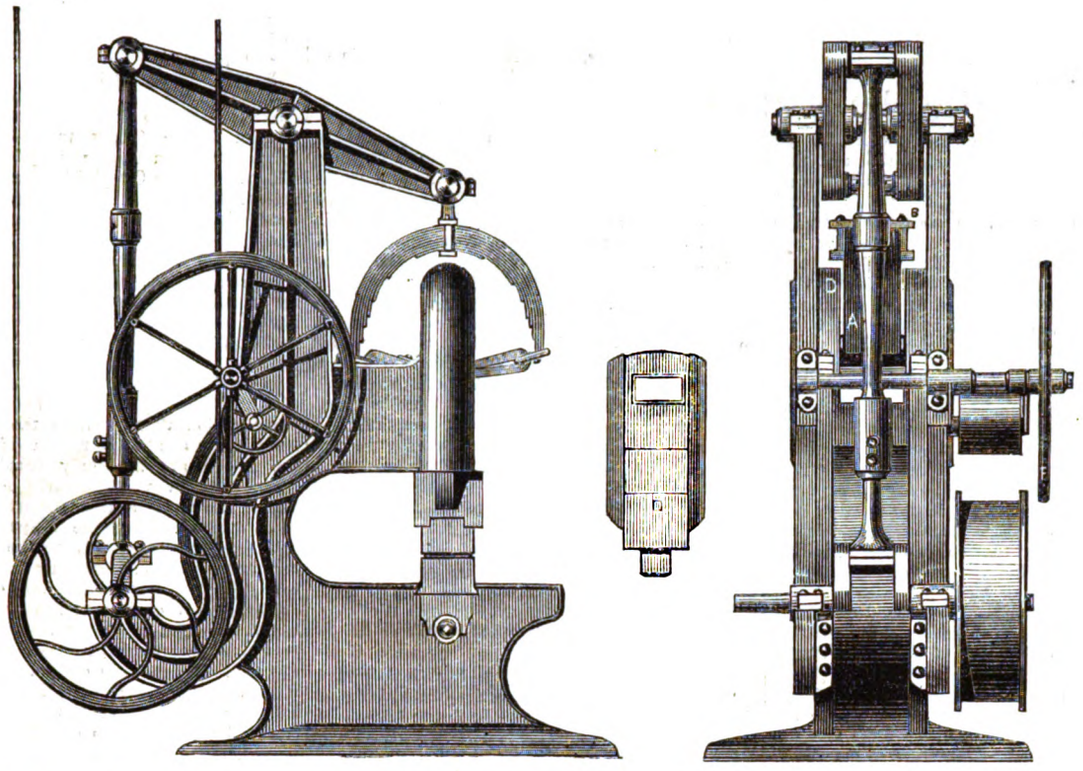
DEAD STROKE POWER HAMMER.

BY MESSRS. SHAW AND JUSTICE, NEW YORK.



firmly after the adjustment has been effected by the screw 14, and 15 is a standing gauge on the bed of the machine, and 16 a similar gauge on the block f^1 (fig. 6), between which a type of the standard width of the dressed type is introduced to aid in adjusting the block f^1.

The blocks f and f^1 carry the pairs of cutters $g\ g\ g$ and $g^1\ g^1$; the cutters g are made with bevelled ends (figs. 1 and 5), and only act to cut off the projecting metal at the base of the letter; these cutters are adjusted by the screws 17. The cutters g^1 act like plane irons upon the entire sides of the body of the types to true the same, making the types uniform in thickness and parallel sided as the line of types is pushed through between the cutters. The cutters g^1 are held down by the clamps 18 that may be turned around to allow of the cutters being removed for sharpening, and screws 19 are provided for adjusting such cutters g^1. The screws also pass through clamps g^2 that have to be turned around to facilitate the removal of the cutters.

The line of types in passing through the channel between the blocks f and f^1 rest upon a bridge h (figs. 6 and 7) is formed with side notches at the parts where the cutters g^1 stand, so that the cutters can project slightly below the bridge, and the bridge at these points is only left the thickness of the thinnest type or space to be rubbed, so that the cutters can be adjusted thereto. This bridge is adjustable by the screws h^1, so that it shall stand midway below the channel whatever may be the width of type that is being dressed. A spring 20 (figs. 5 and 6), is employed to push the block f^1 into contact with the adjusting screw 14, as that may be moved, and thus facilitate adjustment.

The surface of the blocks f and f^1 are made of steel and ribbed, as seen in figs. 5 and 6, so as to lessen friction on the sides of the types as they are forced through the channel. The types are received line by line as they are rubbed into a galley k that has an adjustable side k^1 to accommodate the length of line, and the side 21 is made also adjustable that it may be set at an inclination if the projections at the top and bottom of the letter make the line of types wider at the top than at the bottom. The side k^1 is also fitted with a spring that it may yield if an extra type accidentally is in the line. The whole column of type in the galley k is pushed along by pushers i operated by the cam i^1 and lever i^2, the rule l being at that time lifted by the cam l^1 and lever l^2. This gives the necessary opening for the next line of types to come in, but before the pushers i draw back the rule l descends to hold up the types in the galley k, and the position of this rule l can be adjusted according to the width of the line of types and the movement of the pushers i determined by adjusting the roller i^3. The lever i^2 is made in two parts, each part attached to the shaft i^4, the shaft i^4 forming the fulcrum of the lever.

A block o is set to slide in a groove in the fence o^1 that forms a continuation of the face of the block f, and from this block o a cord passes over a pulley to the weight o^2, so that the first type in the advancing line of types will be held up as the line is pushed into this galley k, and this block is drawn back by its weight o^2 as soon as the line of types has been pushed away from the fence o^1 into the galley. A movable galley k^2 extends from the galley k, the thin sides of this galley k^2 setting behind springs at the edges of k, so that the types cannot become wedged in passing into the galley. The advancing end of the column of types in the galley k or k^2 is held up by a sliding block t. By dividing up the column of types in the galley k^2 into square sections, and then introducing rules so as to separate the types into lines, they may be run through the machine a second time to dress the other sides of the body of the types, the cutters being adjusted accordingly.

DEAD-STROKE POWER HAMMER.

WE illustrate, in the accompanying engraving, a hammer, of American invention, which has been found to give satisfaction to most of the firms who have tried it. The inventors intend it to supersede the trip hammer. The first working model, with a 60lb. head, has been in use for some time past in Philadelphia—principally in drawing down the ends of railway spring blades. The hammer consists of a framework of cast iron about 5ft. by 6ft. 8in. by 10ft. 8in. high. The weight of the hammer is 1000lb., or nearly half a ton, suspended from the spring A, which is attached to the end B, of a beam worked by the crank shaft which is driven by a belt pulley. F is a wheel for tightening the belt, so as to regulate the speed at which the hammer works. The inventors say that it must not be supposed that the power obtained from this hammer is due to the momentum of the ram merely; the principal agent is the elastic force of the steel bow spring, a force that is proved by bracing its extreme points so as to prevent any flexibility, when it will be found that with all the velocity given to the ram, no power can be obtained from it other than that of an accelerated drop or dead fall. Absolute tests prove that a weight of 2500lb. must be exerted to compress the spring usually attached to a 100lb. hammer, to enable it to reach the maximum point of deflection when driven at its regular speed. By this it will be seen that the increase of force over the mere weight of the ram itself is greatly in excess of that of any hammer known, while the power used is economized in about the same proportion. The machine gives a dead blow, and works with a considerable saving of power as compared wtth ordinary drop hammers.

SOCIETY OF ENGINEERS.

(Concluded from page 149).

THE ATRATO AND TRUANDO LINE.

IN 1853, R. G. Jameson, M.D., of New York, explored the tract of country between the Jurador and the Salaqui, but found the dividing ridge to be 1,063ft. high and 30 miles in width. Immediately afterwards he explored the country a little south of it, from the Atrato and Truando to the Paracuchichi. A survey of the latter route was then made in 1854, 1855, and 1866 by Messrs Kennish, Nelson, Rude, and Jameson, at the expense of F. M. Kelley, Esq., of New York, by whom their survey was published.*

In 1857, the United States' Government sent the schooner "Varina" with a commission, consisting of Lieutenant T. Augustus Craven, U.S.N., hydrographer; Lieutenant (now Brigadier-general) Nathaniel Michler, U.S., Topographical Engineers; John de la Camp, Esq., geodetic surveyor; W. H. W. Campbell, Esq., astronomer and meteorologist; Arthur Schott, Esq., botanist and geologist; Theodore Gill, Esq., zoologist, and a number of assistants, by whom, in seven months, a detailed survey of the line was made. Lieutenant Craven published his report separately.† The reports of the other gentlemen are bound together in a volume, which is decidedly the best survey that ever appeared of any part of Central America or the Isthmus.‡ It is accompanied by a large volume of plans§ of extraordinary accuracy and minuteness. In future, no engineer should undertake the examination of any part of the Isthmus without having studied those two works. Before this expedition went out, the author applied to Mr. Toucey, the Secretary of the Navy, requesting that the engineer might be commissioned to survey the Darien route after he should have completed his examination of the Atrato line, and offered to go out, at his own expense, to join the expedition, for the purpose of acting as guide across Darien. But Mr. Toucey, in reply, stated that the survey would be limited to the Atrato line. He then forwarded a number of documents, containing information that might be useful, through Mr. Dallas, the American Minister, who, in a note to him, says:—"These interesting and important documents will be forwarded by me to the United States by the steamer 'Asia,' which leaves Liverpool to-

morrow." It may not be irrelevant to state that, before Messrs. Kennish, Nelson, and Rude, who were Manx men and United States' citizens, went on their first expedition to the Atrato, the author, being then on his way to Darien for the third time, met them at Carthagena, and informed them that the valley of the Atrato, from the source to the mouth of the river, had been examined, in separate portions, by T. C. Vincent, Esq., of New Park-street, Southwark, and Don Juan de Dios Ulloa, a Granadian engineer and native of Quibdò, that he also had examined the mouths of the Atrato and the Cordillera south of Point Garachinè, and that the result of their observations had led them all to the same conclusion, namely, that there was no practicable line for a ship canal between the Atrato and the Pacific. The same opinion had been expressed by Dr. Robert Key, a Scotchman, who had been a surgeon-major in St. Martin's Army of Liberation in Peru, and had afterwards settled in Quibdò, where he resided for thirty years, practising *por el amor de Dios*, and maintaining his family by bartering goods for gold-dust. Nevertheless, they sailed for the Atrato, and, on entering it, their vessel, the "Stella," was wrecked in the Cano Coquito, where its hull was still visible in 1858. They returned to Carthagena to get another boat, and the author had the pleasure of spending many evenings in their company before he started for Darien.

The line surveyed was from the mouth of the Cano Coquito, up the Atrato due south, to the mouth of the Truando—75¼ miles—and up the latter, for a distance of thirty-six miles, to the confluence of the Nerqua, the course being S.W. The line then follows the valley of the Nerqua for thirteen miles, to the foot of the falls of the Hingador. The latter descends from the dividing ridge by a series of cataracts, one of which is 180ft. in height and 40ft. in width. Here the scenery is superb and enchanting to the lover of the picturesque, but very depressing to the spirits of a canal projector, as, besides the great Salto, there are many smaller ones, of 20ft. et infra. The dividing ridge has an elevation of 947·44ft. above the sea. This ridge and a little table-land being crossed, the sources of the Chuparador are reached, and, following down this river to the foot of the mountains, the line crosses the Chupipi, and then follows the Totumia to the Paracuchichi, which falls into the Pacific between Cape Marzo and Punta Ardita.

From a point about three miles above the mouth of Cano Coquito the Atrato is navigable for the largest vessels up to the confluence of the Truando with it. At Boca de Sucio, a little below that point, the height of the Atrato was found to be 25·73ft. above that of Cano Coquito. At the confluence, the Atrato is 350 yards wide and 50ft. deep. The Trunado passes through an alluvial plain, and across two deep lagoons before entering the Atrato. Its average depth is 14ft., but near the junction of the Nerqua with it there are several falls. This river would require to be deepened for its whole length, and the falls should be avoided by a tunnel of 1,000ft. From the tunnel a canal should be cut, on solid ground, along the valley of the Nerqua to the Hingador. From thence a tunnel, 12,250ft., or about 2½ miles, would be required. From the Pacific entrance of the tunnel an open cut, eight miles in length, to the mouth of the Paracuchichi, would complete the communication.

The line would then consist of :—

	Miles.		Feet.
Navigation of the Atrato...	75	...	1,320
" Truando	36	...	...
Tunnel	...	...	1,000
Canal	13	...	...
Tunnel	2	...	1,690
Canal	8	...	...
	134	...	4,010

The following is the estimate of Lieutenant Michler and Mr. De la Camp, who give all the calculations upon which it is based very minutely :—

	Cubic yards.	At per cubic yard.	Cost in dollars.
Earth excavation	75,258,100	33 cents.	24,835,173
Rock cutting.....	43,183,300	1 doll. 50 c.	64,774,950
Tunnel	5,598,000	2 dolls. 50 c.	13,995,000
Total	104,049,400		103,605,123

Some other works bring the totals to 151,300,100 cubic yards of excavation, and 134,450,154 dollars, or £28,010,448 15s. This estimate is very little higher than that given by Dr. Jameson, some years before, in a letter to the "New York Herald."

So far for the engineering work. But the hydrographic survey, by Lieutenant Craven, shows that the subaqueous excavation would be by far the most difficult and expensive part of the work. The bar at the mouth of the Paracuchichi is dry at low water, and Kelley's Inlet, inside of it, has only a few feet of water. Humboldt's Bay, the Puerto Quemado of Pizarro, immediately south of the Paracuchichi, is an open roadstead. A harbour would, therefore, have to be made on the Pacific. But even more formidable difficulties occur at the mouth of the Atrato. The sand-bank off the mouth of the Cano Coquito should be removed. The bar at its mouth, one mile in length, should be dredged from a depth of 3ft. or 4ft. to that of 30ft. Its channel should be deepened for the length of 4.546 yards, from the bar up, from an average depth of 9ft. to that of 30ft. The difficulty of these operations would be greatly enhanced by their peculiar unhealthiness; for it is well known that the most deadly work in the tropics is the disturbance of mud in places where fresh and salt water meet. Even the negroes of Demerara, Essequibo, and Berbice, which are the lowest swamps in the world—the empoldered or trenched and dammed land of the plantations being several feet below the level of the sea—would not stand it. They dread, above all things, the job of removing the drift-mud that sometimes blocks up the Kokert doors, through which the surplus water of the canal is let off at low water—and with good reason—for they generally get the ague after it.

The following letter gives the results of Lieut. Craven's survey :—

"Bound Brook, New Jersey, August 3, 1858.

"DEAR SIR,—I received your communication of January, while on my return from the Atrato. I arrived in the United States early in May, having made a thorough examination of the route by the Atrato, Truando, Nerqua, and Totumia rivers. The entire distance across is 134 miles, which I twice traversed with the parties under my command. My preliminary report was made to the United States' Senate on the 17th of May, and has appeared in our papers generally. I suppose, therefore, you have seen it. I do not say that the construction of the canal is an impossibility; but its cost will be immensely beyond the views of this age. My detailed report is not made out, but I believe that my estimates will reach some 500,000,000 dollars with fifty years of labour. In a matter of such consequence to the world, it is very important that a practicable route be discovered. If nothing better offer, we must cut through the Isthmus at Panama.—Yours truly,

"T. AUGUSTUS CRAVEN.

"Dr. Cullen, 302, Strand, London."

The author saw Craven afterwards on board the United States' frigate "Tuscarora," of which he was captain, and in which, it is deeply to be regretted, he was lost, and he said that the idea of opening a canal by way of the Atrato had been abandoned.

The table-land at the summit of the ridge is composed of trappean or metamorphosed schistose rock, covered by broken secondary and tertiary strata. The Divide is composed of alluvion underlaid with recent layers of loam, sand, semi-rock, and conglomerate. At the foot of the great fall of the Hingador there are thermal springs; and in the valley of the Nerqua, there is one of the temperature of 107 deg. Fah. The principal palms are known by the native names of Milpesos (1,000 dollars), Chontaduro, Pihiguai, Hipihapa (of which the Panama hats are made), Palmiche, Coroso, Puertorico, Quitasol, Palma Amarga, and Murapo. They appear to belong to the genera Bactris, Martinezia, Areca, Aiphanes, and Carludovicea. There is a bread-fruit tree, called Membrillo, which probably belongs to the order of Lecythidaceæ. The greater part of the region of the lagoons is covered with a thick gramineous vegetation, interspersed with water plants, mostly Alismaceæ, Polygonaceæ, Pontederiaceæ, &c., &c. Gramalote (Panicum glaucum) is abundant, and is the favourite food of the manati, or sea cow. Lichens, Jungermanniaceæ, Lycopodiaceæ, and a whole host of parasitic suckers in the shape of Orchidaceæ, Bromeliaceæ, Filices, Aroideæ, &c., overspread the district. Amongst the trees are the water-loving Cecropia peltata, which bears the vernacular name of Guarumo; an Inga with eatable pods (Guamo); a mimomaceous tree with a graceful umbellate crown, and the Trementin, a grave forester with a conical base, whose trunk does not send off any branches until it reaches 80ft. or 100ft. in height. Mr. Gill mentions among the Gnawers, the Cavybara, the Agouti, and several species of Sciuridæ; amongst the birds several species of Scansores, Rasores, Columbidæ, Conirostres, and Grallatores. Of the fishes he has written at very great length.

The population is very small indeed. The Truando is totally uninhabited. On the Nerqua, a mulatto, named Domingo, and two or three families were the only inhabitants. There they met an Indian family travelling, and there is from thence an Indian trail across the Cordillera. On the Chupipi there are a few families; and at Paracuchichi mouth there are twelve houses inhabited by samboes and negroes from Panama, and a few Jamaica men, who are described as ex-pirates, thieves, wreckers, and sharpers. They demanded most exorbitant prices for conveying the baggage of the expedition across the Cordillera. Some of these people make trips in bongos to Panama, which is 165 miles N.W. They generally call in, on the way, at Garachiné village, eighty miles distant. This population had only been ten years settled there. With the exception of a few families at the mouth of the Jurador, the above are the only inhabitants in the country which was formerly called Biruquete and is the most southern part of Darien, extending from Garachiné Point to Cape Marzo, and from the Cordillera to the Pacific. About twenty years ago it constituted a district under a corregidor and was called the corregimiento of Jurador, but of late it has been entirely neglected. It used to be the resort of Cimarrones, or runaway slaves and fugitive criminals from Panama. It was this coast that Pizarro visited when searching for Peru, and it was from the wrong application of the name of the Biru (called by Pizarro Rio de Hambre, or river of famine, and now Rio Jurador), that the name Peru was derived. On the Biru was the village, the inhabitants of which he called Pueblo Quemado, or burnt people. The Biru had been visited some time before by Vasco Nunez, and then by Andagoya, and Almagro called there in pursuit of Pizarro.

The following are the principal points of which Mr. Campbell fixed the positions :—

	Lat. N.			Long. W.		
	deg.	min.	sec.	deg.	min.	sec.
Turbo, on the E. side of the Gulf of Darien, nearly due E. of Cano Coquito	8	4	56·2	76	41	50·7
Boca de Sucio, a little below the Truando mouth	7	26	16·6	77	5	40·5
Paracuchichi mouth ...	7	2	59·6	77	40	25·35

The thermometer during December, 1857, ranged from 79deg. to 83deg. from sunrise to sunset.

THE PALLISER GUN.

IT is agreeable news to hear that the success of the efforts of the Ordnance Select Committee to provide the country with cheap guns, in order to arm as rapidly as possible the forts and batteries at home and in the colonies with rifled cannon, promises to be complete. A cast-iron 32-pounder, converted by Sir W. Armstrong and Co. for the Victoria Government, on Major Palliser's plan, fired some seventy-six heavy charges at Shoeburyness, as much, we—"Army and Navy Gazette"—believe, as 16lb. of powder and 80lb. shot. The gun was afterwards condemned by the Woolwich authorities, and submitted by the Ordnance Select Committee to the trying test of 2,000 rounds of service charges. It has just completed its task, having got through 2,076 rounds without injury, beyond a few scratches in the b ore to the depth of one-tenth of an inch. This result is a proof of the extraordinary pitch of excellence to which the Elswick Ordnance Company have brought their coiled barrels. It is stated, indeed, that their converted 68-pounders have been firing battering charges at Shoeburyness usually allotted to much heavier ordnance. Colonel Clarke's strengthened carriage answers admirably, one of the converted 68-pounders having fired 100 rounds from it with 22lb. of powder and 115lb. shot. Nothing could be better than the way the carriage behaved. Altogether the country is to be congratulated on the results of the efforts of General Lefroy and the officers of the Ordnance Select Committee. We hear that their report will soon be printed and laid on the table of the House.

A PICTURE attributed to Murillo has just been discovered in the church of Villaharta, in the province of Cordova.

HÆMATITE IRON ORE IN SCOTLAND.

THE presence of ironstone in the volcanic rocks which form the greater part of the Garleton Hills has long been suspected, but its abundant existence and richness have only very recently been demonstrated. The important discovery was made by a local farmer, Mr. Aitcheson, of West Garleton, who in turning the soil was struck with the frequency with which the plough brought fragments of ironstone to the surface, as if broken off from larger masses beneath. Knowing something of the value of the ore, he recommended the proprietor of the land, Sir T. B. Hepburn, of Smeaton, to make a systematic examination of the hill to test the character of the underlying rocks. Mr. Robb, a local geologist, strongly urged that the ground should be at once examined. This was done, and after breaking ground without success at several points, the search was at length rewarded by the workmen coming on veins of hæmatite iron of the richest and most valuable character. The vein, where at present struck, crosses the hill in a slanting direction from the south-east to the north-west, and has been traced nearly along the whole breadth of the hill, a distance of some four or five hundred yards. In some places the ore is met with in small boulders, interspersed with the ordinary trap rock of the hill, and in others it is met with in a solid mass of as yet unknown depth. This occurs on the crest of the slope, the iron being within 5in. or 6in. of the surface, and penetrating downwards in a solid bed. At present the workmen have uncovered this section of the vein to the depth of 7ft., without any appearance of its termination; and as veins of a similar character are in all probability to be met with in immediate proximity, there cannot fail to be many thousand tons of ore. Hæmatite iron has nowhere else been found in Scotland, the well-known blackband being the only description of the ore hitherto met north of the Tweed.

THE "WATERWITCH."

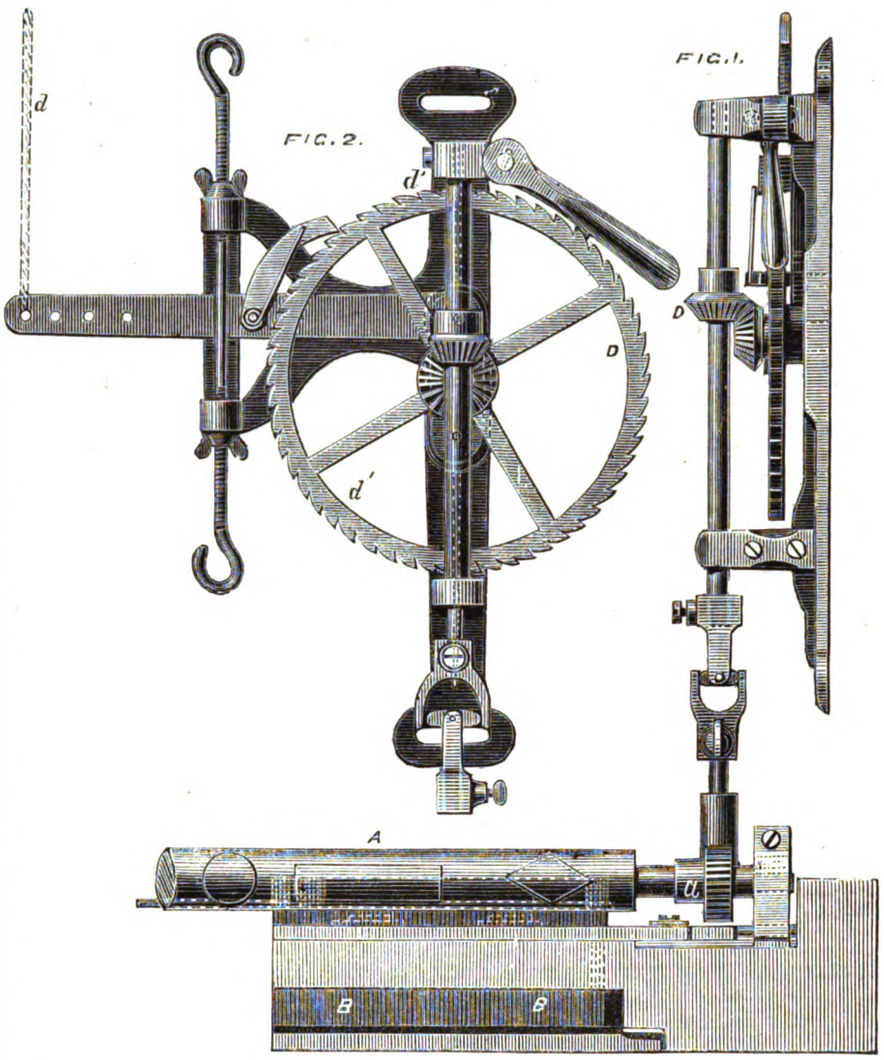
THE alterations to the hydraulic propelled gun-vessel "Waterwitch" having been completed, the ship has been put through trials of her machinery and speed prior to sailing on a competitive Channel cruise with the twin screw gun-vessel "Viper." The trial of the ship's engines gave highly satisfactory results. In her trial of speed over the measured mile in Stoke's Bay, her draught of water being 11ft. 2in. forward, and 11ft. 9in. aft, or a mean draught of 11ft. 5½, the mean of six runs over the mile with full boiler power gave the ship a speed of 8·880 knots per hour, with an indicated power by the engines of 785 horse. Four runs with half-boiler power gave the ship a speed of seven knots per hour, with an indicated power by the engines of 370 horse. The engines fully sustained their reputation for development of power, smoothness of motion, and general efficiency. Any further trials of speed made with the ship should be made with experimental alterations in the blades of the turbine, or water-wheel, or in the trials of a different form of wheel. The engines of the ship, as the driving power of the wheel, are reported to be perfect.

STEAM FIRE ENGINE FOR SHIPLEY.

THE Local Board of Shipley has purchased one of Merryweather and Sons' medium size steam fire engines of the same pattern as the engine "L'Imperatrice," one of those for which this firm was awarded the only gold medal given to any description of fire engines at the late Paris Exhibition. The engine is one well suited to the hilly districts of Yorkshire, its weight being but 31cwt. and its power equal to four or five large size hand fire engines, as it discharges over 400 gallons per minute; it is of the makers' horizontal long-stroke single-cylinder pattern, with a steam cylinder 8in. diameter, and double-acting pump 6¾in. diameter, with 18in. stroke of steam and pump pistons. At the various tests made at Shipley it has given excellent results, discharging water to a height of 170ft., raising steam from cold water to a pressure of 100lb. per square inch in less than ten minutes. The engine is so arranged that steam can be got up and the fire attended to *en route*, and to carry nine or ten firemen and a sufficient quantity of coals; it also has a powerful brake to be used when descending hills. The celebrated mills of Saltaire are in the Shipley district.

APPARATUS FOR THE MANUFACTURE OF WATERED FABRICS.

BY M. TAVERNIER.



APPARATUS FOR THE MANUFACTURE OF WATERED FABRICS.

IN the watering of silk there are two processes employed to produce the fabrics which are known as the moire antique and French watered silk. The first is distinguished by the varied appearance and irregularity of the grain of the fabric produced after weaving by rolling and folding; and especially by the aid of great pressure, which crushes the fabric, so to speak, and fixes the pattern. The designs obtained by this mode of watering formed at hazard by the folds of the fabric, although bearing a general resemblance as regards their formation, cannot be easily reproduced at the will of the operator. The French watering resembles moire antique in so far as the twisting of the grain after weaving is concerned, except that it is produced by strong tensile force applied longitudinally, which reverses the grain in passing over different points, considerable pressure being then applied to flatten or fix the design so produced. This kind of watering produces designs which, if not identical, at least succeed each other in an almost regular manner in straight patterns. These two kinds of water are remarkable for monotonous uniformity of tone and effect, and can only be obtained by stretching or weakening the fabrics more or less, the grain being not only wrenched but drawn in opposite directions.

To obviate this, and in order to produce effects which may be predetermined by the manufacturer, instead of being as now imperfect and governed by chance, M. Cesar Tavernier, of 29, Boulevart St. Martin, Paris, has invented the machine represented in the accompanying engraving, and which has been recently patented in England. This invention insures the production of the most varied watered designs which may be simple, such as squares, lozenge shaped, round, oval, or it may be flowers or ornaments, and arabesque designs of a more complicated nature, which are determined by the taste and skill of the artist, these designs being capable of reproduction as often as desired. This is effected by causing the threads during the weaving of the fabric to produce at certain points only of the fabric the combinations of light and shade termed watering, the pattern of which is previously decided instead of being due to chance only when produced after the weaving as usual.

The improvements consist in operating various degrees of tension at different points of the fabric to facilitate the production of the design, for which purpose the operator acts either on the warp or weft threads or on both simultaneously, varying the tension of the warps or beating the weft up with different forces. The variation in the tension is produced in the warp threads by classing them in groups, each group having separate bobbin beams or rollers, which warps are supplied at different degrees of tension during the weaving. The variable beating or tension is obtained by the aid of an additional reed, the teeth of which are fixed at one end, the other ends being free, but arranged in such manner as to be readily fixed when desired by the application of a part in the rear. All the teeth so fixed beat up the weft with a certain force, while the free ends of the teeth being deflected by the beating action will only slackly act on the weft, thus producing a variation in the beating. The beating may be constantly tight or slack for the same teeth of the reed, in which case the parts interposed are fixed or varied by series of teeth or separate teeth, the parts also moving in series or separately. The action of the parts is produced by the aid of a roller having variable rotary motion imparted to it according to the requirements of the fabric. This roller has relief surfaces on its periphery acting on the parts above mentioned, causing them to approach or recede from the free ends of the teeth of the reed. By varying the speed of the cylinder different effects may be obtained, or, if desired, the cylinder may act directly on the teeth.

Digitized by Google

Fig. 1 of our engraving represents a front view of part of a batten provided with a roller, and also showing the mode of actuating the same; fig. 2 is a transverse section of same. A is a metal cylinder provided with relief surfaces acting on the oscillating levers B whereby to bear on or release the free end of each tooth of the reed, there being as many levers provided as there are teeth of the reed to be deflected. D is the mechanism for rotating the cylinder A at each throw of the weft; motion is imparted by the cord *d* acting on a ratchet d^1, and thence transmitted to the endless screw *a*.

DR. LIVINGSTONE.

THE following information, relating to the illustrious traveller, appears in the "Natal Mercury" of the 11th January, having been reproduced from the "Transvaal Argus," received in December:—Mr. Marthinus Swarts, the elephant hunter, who has just returned from one of his annual shooting excursions in the interior near the Zambesi, informs us that in June of last year he spoke to some natives who had accompanied the great traveller, whom they call "Minarie," signifying "Good," the name to which Doctor Livingstone is known to the natives. These men Mr. Swarts met three days' journey north of the Victoria Falls, who informed him that in the beginning of April last "Minarie" (the doctor), stated to them that he was now going away, and dismissed them, giving them various presents, and also sending presents by them to Retanga. This took place at a certain spot twenty days' journey on foot from where Mr. Swarts met them, and close to some very large river which runs in an easterly direction. Retanga is chief of the Barootsi, and Cepopo is his chief captain. This very large river has its sources at some distance from the Debebe, and is described by the natives as considerably larger than the Zambesi. Mr. Swarts further says that the coast cannot be very far distant, as the natives had sea shells in their possession, which they stated they had got from the big water, meaning the sea. Mr. Swarts also says it would be impossible for the Doctor to transmit any letters, as no native could be induced to carry them beyond his own tribe, for venturing beyond certain death to the messenger would be the consequence. So far as we know, this very large river is not laid down on any map, and, being hitherto unknown, it is very probable that the Doctor, after dismissing these native servants, had proceeded to explore it, intending to reach the coast at a point where this river discharges itself into the India nOcean.

FIRES AND FIRE ENGINES IN PARIS.

A STATISTICAL return has been made of the number and nature of fires which have occurred in Paris from 1840 to 1860 inclusive. During these twenty years there were 5,472 conflagrations, exclusive of 23,056 chimney flues catching fire. The total damage done amounted to 16,457,344f., being an average of 820,000f. per annum in round numbers. This sum, large as it is, cannot be compared to the losses experienced in former days, before the precautions against such disasters had reached the point of perfection at which they now are, and when scarcely any other remedy was attempted but that of pulling down the adjacent houses, and parading the Holy Sacrament in procession along the streets. From some further information on this subject given by "The Times," it appears that the first fire engines came into use in 1699, and a M. Dumourier-Duperrier was appointed director-general of these engines, the number of which was fixed at thirteen. In 1716, after a violent fire which broke out in a wax chandler's shop at the corner of the Rues St. Martin and Neuve St. Mery, and which threatened to destroy the whole quarter, the number of fire engines was increased to thirty, which were distributed among the different quarters of Paris. M. Dumourier, who, in virtue of his contract, had instructed thirty-two firemen in the management of the engines, was now obliged to raise the number of these *gardiens* and *sous-gardiens* to 120, and to provide them with uniforms. He received 40,000 livres for his first outlay, and 20,000f. per annum for the pay of his men, the keeping his engines in repair, &c. The city soon after organized a fire brigade of its own, under the direction of the Prevot des Marchands. Fire engines were known long before 1699, in other countries in Europe; it was the Dutch model which Dumourier introduced at Paris. The organization of fire brigades was frequently improved, and more particularly in 1811. In future, when the plan of the city for raising water to the tops of the houses shall have been carried out, fire engines will become almost useless. Every house will be provided with a main-pipe, to which a hose may be screwed at a minute's notice, and the firemen will merely have to turn a cock in order to get an indefinite supply of water, and direct it to the proper spot without pumping.

IMPROMPTU ON AN AMERICAN BLOWING ENGINE.

Whene'er 'tis wished to make a noise
One generally *brass* employs,
As in the present case; and here
I think it really doth appear
That *brass* is put in its right sphere,
For all good engine makers know
That steel on brass does sweetly go
At any speed, or any rate,
If them you well do lubricate,
And let them run, they'll go all right,
Provided they're not kept *too* tight—
But when, through want of care or thought,
Good "lubrication" is forgot,
Then "brass" and "steel" do not agree
(As in this case we yet may see);
And when it happens t'will be seen
The "Blowing Engine" stops—I ween.

ROLLS' COURT.

February 19.

(*Before the* MASTER OF THE ROLLS.)

THE ACCLIMATIZATION SOCIETY OF LONDON *v.* THE ROYAL ZOOLOGICAL SOCIETY.

THIS was a bill filed by the Acclimatization Society against the Zoological Society and Mr. Jeffries Stone, the amateur naturalist, of Ewell, Surrey, and Monmouthshire, to compel the delivery up of some valuable game birds, alleged to have been delivered by Stone to the Zoological Society, when in reality the birds belonged to the Acclimatization Company. Our readers are doubtless aware that the latter Society was formed in 1860 for the purpose of introducing, acclimatizing, and domesticating in this country foreign birds, fishes, insects, and vegetables, and of propagating the breed of them as much as possible. In 1865, Mr. Jeffries Stone, then a member of the Council of the Acclimatization Company, obtained a promise from Mr. Medhurst, our Consul at Hankow, in China, that he would send him over some rare pheasants (known as Reeve's pheasants, Lady Amherst breed, and Tragopans.) In 1866, the secretary of the Acclimatization Company wrote to Mr. Medhurst to remind him of his promise to Mr. Stone, whereupon Mr. Medhurst replied that, instead of forgetting his promise, he had taken a good deal of trouble to honour it, and had made two shipments of the promised birds to Mr Stone, and intended to send more as opportunity offered. It was then discovered that the birds sent by Mr. Medhurst had been intrusted by Mr. Stone to the Zoological Society, and hence this suit. The Zoological Society refused to give up the pheasants except to Mr. Stone, and this gentleman refused to part with his right of possession on the ground that Mr. Medhurst consigned the birds to him personally, quite independently of any consideration as to whether he belonged to one society or another. Mr. Stone's position was supported by an affidavit of Mr. Medhurst, who admitted that in whatever he did he meant to oblige Mr. Stone mainly, being satisfied that Mr. Stone would do the best he could for the public in attending to the breed of the birds, and sending them, as he thought fit, to proper depositaries.

The Court gave judgment on Friday last, holding that the Acclimatization Society had failed to make out the case alleged by their bill, which was, therefore, dismissed with costs.

Mr. Baggallay, Mr. Southgate, Mr. Cracknall, Mr. Downing Bruce, Mr. Kekewich, and Mr. Latham appeared in the case.

Correspondence.

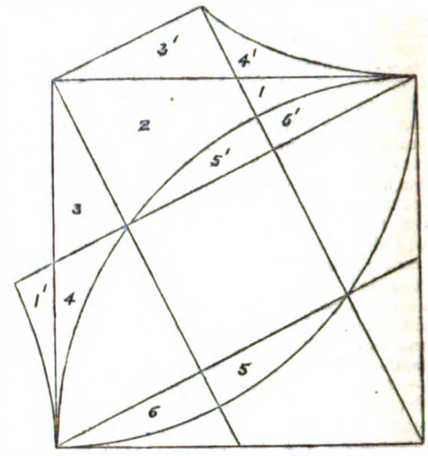
SQUARING THE CIRCLE.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—Your correspondent, Mr. Harvey, will find, in the preface to the "Nautical Almanack," the use of trigonometrical lines in determining the relative positions of the celestial bodies. The correctness of the values of trigonometrical lines, based upon the long accepted ratio of the circle to its diameter, is verified by the fact that the computed positions of the celestial bodies agree exactly with their observed positions.—I am, Sir, yours, &c.,

February 23. COMMANDER, R. N.

SIR,—I have carefully read that part of Mr. Harvey's last letter (No. 10), describing the diagram accompanying it, but I cannot see how the four spandrils are proved to be equal to one-fifth of the tangent square of the circle, and I herewith send a part of Mr. Harvey's diagram (No. 10), and will



thank him to prove that 1 and 4 are together equal to 5 and 6 separately, which correspond to 5' and 6'. If Mr. Harvey can do this, I will admit that the inscribed circle contains four-fifths of the tangent square; but it appears to me that Nos. 1 and 4 are together considerably in excess of 5 and 6, when taken separately, and this is more noticeable when they are jointed together, as in the diagram now sent. (See Nos. $1^1.4$, and 1.4^1. I am much obliged to "A. W." for his acknowledgment of the closeness of my approximation, which I think is rather nearer the truth than he states, as from some carefully executed drawings which I have just made, it appears nearer than what the tables of areas make it, that is, instead of being one-half per cent. too little, it does not look to be much more than a fourth. With reference to Mr. Nicholson's remark about the rule I have mentioned for finding the circumference, I beg to inform him that it gives a trifle more than three times the diameter and one-seventh, and that the depth of the segment of which the side of the inscribed square is the chord is more than twice the depth of the segment of which the radius is the chord, and not less, as he states in his letter.

My approximate solution of the problem, besides giving exact ratios to the inscribed and tangent squares, enables a circle to be drawn nearly equal to a given square, by simply taking two-fifths of the diagonal for a radius, the circle in this case being a very little larger than the given square.—I am, Sir, yours, &c., WM. HAYDEN.

Chichester, February 22.

SUGGESTIONS ON THE DEFENCE OF FORTRESSES.

No. V.

SIR,—The present letter on the above subject should be considered as explanatory of and supplementary to various suggestions made in former and to be made in future letters. In my last letter I suggested the employment of balloons for the purpose of dropping shells of a peculiar shape upon the enemy's ships; and it may with truth be said that the enemy may retaliate in the same fashion. Now, although it is to be hoped that at the time when aerial navigation will have reached such a degree of perfection that our aerial trains would run as regularly and brave wind and weather in the same way as our steamers do on the surface of the sea, common sense will have made proportionate progress in real civilization, so that then human courage, ingenuity, and talent would be chiefly occupied in warring with the elements,—still, that time, if ever it comes, is many generations yet ahead of us, and meanwhile we must take things as they are, including aerial navigation with all its imperfections. From some of the following remarks it will be seen that both in the employment of stationary (anchored) balloons for purposes of observation and reconnoitering, as well as the bomb balloons formerly alluded to, for the purpose of doing damage to the enemy, the defenders of a fortress or fortified harbour will, in many respects, enjoy particular advantages; in any case, they invariably will have plenty of time for making their arrangements and for carrying on their operations on a well-considered and maturely-planned system.

In my letter No. III., I alluded to a peculiar class of rifles of extraordinary large size, for the purpose of throwing projectiles to very great distances; such rifles, constructed on the very best system, would be mounted on the towers* and other elevated parts in our fortress in such a manner as that, when mounted, they would bear some resemblance to the telescope in theodolites and astronomical instruments—

* The construction and relative position of these towers will be described in a future letter.

Digitized by Google

one or more telescopes being mounted in the same frame with the rifle, and the whole arrangements being so contrived that the rifle could be adjusted and fixed at any required angle with mathematical precision, and any given point within range be fired at with the certainty of being hit. I mentioned the employment of stationary telescopes in connection with these rifles, and I may here add that such telescopes may also be advantageously employed for general purposes of observations, independent of such rifles,—in which case such telescopes would likewise be mounted somewhat like the telescope is in a theodolite, with similar accessory parts for correctly determining horizontal and vertical angles; only in our telescopes, as well as the rifles before mentioned, the vertical arcs, horizontal limbs, and all other parts, ought to be of a much larger size, and more substantially made, so as not easily to get out of order even if handled by rough hands. It will be seen that, as throughout our works, and at distances from each other, we should have several such reconnoitering stations or terrestrial observatories, the distance between each two of which observatories forming a base-line of well-known length, the exact distance of any object seen from any two of such stations could easily be determined with mathematical precision, without delay, at the moment such object appears; and as all the stations are in electro-telegraphic communication, not only with each other, but also with all the other parts of the work, the exact distance of such an object from any given point could at the same moment be communicated to the batteries, which would thus be enabled, without trouble, to bring their guns to bear at the proper range, so that, in addition to the fire of our big rifles, the guns of our batteries would, in a measure, be guided, as it were, by our observatories. I leave your readers to judge how much more effectual the fire and how much more simplified the handling of our batteries would be rendered by such an arrangement; and it may easily be imagined how very annoying to the enemy would be our thus "surveying" (in the American sense of the word*) the surrounding land and sea surface by means of our long-range rifles.

The fixed aim lines, and the prepared tables of aim lines alluded to in my letter, No. IV., would be intimately connected with the above arrangements for determining angles and distances; and the turntables, gun-carriages, rails, turrets, and other similar parts of our works, should also be graduated and marked in such a manner that they could be used independently as very large scale horizontal limbs, and vertical arcs, &c. Now, even supposing that the enemy also should employ balloons, I venture to say, that, thanks to the above arrangements, the defenders would have greatly the advantage over him—for his balloons could be disabled by means of our monster rifles before they could do us any harm; while the unavoidable absence on his part of such carefully-planned arrangements for observation and precise fire, which we have had ample time to prepare, would obviously prevent him from returning the compliment as regards our balloons. I may add that additional advantages may be derived from the use of explosive bullets in our large rifles. In the campaign of 1866, in Germany, several Austrian ammunition waggons were blown up by Prussian explosive rifle-bullets. Owing to the necessity of having to receive a specially careful training, the men attending to the above observatories and guns would form a special branch of the service. In fact, on comparing the present state of the art of war with what it was only thirty or forty years ago, we find that, owing to the influence of art and science, a number of special services, never before dreamt of, have sprung into existence; take, for example, the department of field telegraphy in the Prussian army; by this department alone, and in a few weeks, about 6,000 miles of telegraph wire were laid down,—each component division of the northern army, and even smaller divisions on important service, spinning like spiders a telegraph thread in their rear wherever they marched to. Another special corps is the field railway corps, by the help of which corps the Prussians, on taking possession of a hostile railway, whence all the *personnel* had been withdrawn, were enabled to run trains in a quarter of an hour as regularly as if they had been doing nothing else for years.

Permit me to mention another instance illustrating the admirable organization of that "army of citizens," and the far-seeing sagacity of its leaders. Near Riesa, the river Elbe is traversed by a large railway bridge which had been destroyed by the Saxons; the Prussians then appeared, and in a very short time the glittering lines of the stern northern warriors were seen pouring across the river on a pontoon bridge. Of course, that was nothing very new to the numerous well-treated and unmolested spectators of the proceeding; but they were puzzled by seeing a lot of waggons laden with mysteriously-shaped and lettered and numbered pieces of timber, which kept at the same time coming up from the rear, and several of which also crossed the pontoon bridge; but very soon, to their utter amazement, their destroyed railway bridge seemed to grow again, as it were, by magic, growing from pier to pier by the well-regulated exertions of a beehive of sturdy Prussian carpenters and other artizans; and soon ponderous trains, laden with war material and troops, thundered over it. That bridge was rebuilt in almost as short a time as it took to destroy it, because the dimensions of all its parts were known to the Prussian reconnoitering engineers, and, anticipating its destruction, all the component parts of a new bridge had been carefully prepared several days before. That campaign proves that the greatest chances of success will ever be with that army in whose organization and handling the discoveries and teachings of modern science and art are most made use of in preparing for and carrying out all the various arrangements and plans; so, also, will the defence of a fortress be rendered the more efficient if all possible advantage is taken of all useful modern discoveries and the improved methods of their practical application, in the planning and construction of the works, in their armament, and the organization and handling of the defending forces. A certain definite amount of work may be performed either by a larger working force in a shorter space of time, or by a smaller force during a longer period; and as regards the construction of new fortifications, or the modification of existing works and their adaptation to modern requirements, I must deem the latter course to be the safest and most economical one, simply because in our age of rapid progress, by making any changes in our fortificatory works only slowly and by degrees, we should, paradoxical though it seem, be better enabled to keep pace with the improvements in the means and mode of attack, because then any changes that may, by such improvements, be rendered necessary in the mode of construction, could be effected with less trouble, less delay, and less expense. On the other hand, were there to be effected on a large scale sweeping, radical changes, with the exercise of great energy, and great sacrifices of money and labour, such energy, labour, and money might turn out to have been expended in vain, if by further improvements in the various apparatus for, and the mode of engineering employed in the attack, such works should turn out to be inadequate for the purpose for which they were destined; hence the government of this country is pursuing a wise course in making such changes in their fortifications and the construction of ships of war by transitions, as it were, from stage to stage, and with great caution and circumspection.—I am, Sir, yours, &c.,

February 25. G. J. GUNTHER.

* An officer of an United States' squadron was asked (while lying some years ago in a colonial harbour), "What are you going to Japan for?" "Merely for a survey—shall draw our lines with cannon balls!" he growled in reply.

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith.—ED. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

Mr. J. BIRD'S (Birkenhead) question is a purely legal one, and his right to recover for the drawings rests upon the terms of the agreement under which they were supplied. As Mr. Bird solicits our opinion, we may tell him that we think his case a very weak one. As he puts it to us it seems as though he had been endeavouring to persuade certain parties to adopt his patent, and had failed. But he should consult a solicitor, who will settle the question.

R. E. T. (Bolton). If you will send your name and address, we will reply to you by letter.

Meetings for the Week.

MON.—Society of Engineers.—Discussion on the papers read on "The Surveys of Proposed Lines for a Ship Canal Between the Atlantic and Pacific," on "The Panama Railroad," and on "The Darien Ship Canal," at 8.30 p.m.
Royal United Service Institution.—Major W. H. Ross, R.A., on "Field Artillery on the Connected System," at 8.30 p.m.
Royal Institute of British Architects.—A Special General Meeting.
Royal Institution.—General Monthly Meeting, at 2 p.m.

TUES.—Royal Institution.—Mr. George Scharf on "Historical Portraiture," at 3 p.m.
The Institution of Civil Engineers.—Mr. Christer Peter Sandberg, A.I.C.E., on "The Manufacture and Wear of Rails," at 8 p.m.

WED.—Society of Arts.—Mr. John Randall, one of the Artizan-Reporters on the Paris Exhibition, on "A Workman's Views on Technical Education," at 8 p.m.

THURS.—Royal Institution.—Mr. George Scharf, on "Historical Portraiture," at 3 p.m.

FRI.—Royal Institution.—Mr. Kingdon Clifford, on "Some of the Conditions of Mental Development," at 8 p.m.

SAT.—Royal Institution.—Professor Roscoe on "The Non-Metallic Elements," at 3 p.m.

Naval, Military, and Gunnery Items.

THE winter general meeting of the National Rifle Association will be held at Willis's rooms, at 2.30 p.m., on Wednesday, the 4th of March: Field-Marshal His Royal Highness the Duke of Cambridge, president, in the chair.

THE Prussian Government has ordered a 9-inch breech-loading gun from Sir W. Armstrong, the powers of which are to be tested side by side with Prussian cannon of the same calibre but different make.

THE whole of the boilers for the "Hercules" have been fitted, and on Saturday the three iron lower masts, the largest ever constructed for a vessel of war, were fitted by means of the floating shears in Chatham Harbour.

MARSHAL NIEL, the French Secretary of State for War, has devoted the spare room at the Invalides into a warehouse containing all the *impedimenta*—field ovens, camp kettles, tents, ambulances, &c.—required for an army of 200,000 men. Everything could be issued at a minute's notice.

THE French government have awarded to Captain George Swan, of the British ship "Phœbus," of Falmouth, a binocular glass, in recognition of his services in picking up at sea the crew of the French merchant vessel "Amiable Virginie." The Board of Trade will cause the reward to be presented in a befitting manner.

SQUADRONS of almost all the navies of the several nations have for some time past been cruising in the Mediterranean. After the American and the English, the Austrian squadron, from the Levant, has just left the Greek waters, and cast anchor in the Bay of Saint Andre, which forms the southern portion of the roadstead of Trieste.

THE monthly report of the Bureau Veritas of Paris shows that in January last 264 vessels were lost, of which 141 bore the English flag, while 35 were French, 24 American, 12 Prussian, 8 Dutch, 7 Norwegian, 5 Danish, and 32 of various other flags. The list of casualties compares favourably with preceding years, there having been 421 losses in January, 1867, and 411 in the corresponding month of 1866.

THE manufacture of war material is going on briskly in Turkey. Great activity has lately prevailed in the gun factory at Tophaneh, particularly in the making of gun carriages and ammunition waggons, in which a large number of workmen are employed. The models used were recently sent out from Woolwich Arsenal. The Muchir has also invited tenders from gunsmiths and engineers for the conversion of rifles into breech-loaders.

ADVICES from Constantinople, says the "Toulonnais," speak of some important measures in course of preparation with a view to arming on a large scale. It is even said that the Ottoman Government, at the same time that it is endeavouring to rekindle Mussulman fanaticism, meditates providing the whole population of that creed with improved arms, so as to create a landwehr like that which exists in other countries.

THE systems of signalling and telegraphing adopted by the American Government are now uniform in the army and navy. The cadets at West Point and the midshipmen at Annapolis receive the same instructions, so that when they become officers in any contingency of land or naval service, they will be enabled to open and maintain communication, by codes of signaling and electric telegraphy identical in their operation.

WE read that a new rifle, superior to any of those recently invented, was submitted to the Emperor Francis Joseph on his arrival at Pesth. The inventor is a Hungarian, M. Mersits de Roob. This weapon, a breech-loader, is said to be of very simple construction. It is charged by two motions, so that thirty shots can be fired in a minute. The envelope of the cartouche costs only 4c. instead of 8c., the price of those recently adopted for the Austrian army.

THE United States' Consul at Liverpool has been instructed by his Government to pay to John Williams, a pilot at Duffryn, and James M'Cartney, one of the crew of the Liverpool steam-tug "Reliance," the sum of 100 dollars each, as a reward for their noble conduct on the occasion of the wreck of the American ship "F. J. Southard," near Duffryn, on the 5th of December last, when at great peril to themselves

Digitized by Google

they managed to get the end of a line ashore and establish communication with the vessel, and thus were mainly instrumental in saving the lives of the crew.

AN American paper states that a certain Walter Brown, of Portland, has a paper boat which is 31½ft. long, 12in. wide, and weighs but 22lb. The lightest wooden boat ever built of similiar dimensions weighed 41lb. The most singular part of the matter is that the boat is more than four times stronger than one of wood. All of it, save where the sculler sits, is gas tight, so that in the event of a race sufficient gas may be taken into it to reduce its weight to 8lb. The displacement of water by such a craft will be very much less than that of a wooden boat, and the same exertion will propel it proportionately faster.

Miscellanea.

IN making some excavations lately in a cellar of a house at Sarreburg, a great number of silver coins with the effigies of Louis XIV. and Charles V. have been found.

THE number of visitors at the Patent Office, South Kensington, for the week ending February 22, was 3,792; total number since the opening of the museum, free daily (May 12, 1858), 1,250,580.

LAST year 1,001,545 acres of land in Ireland were devoted to the growth of potatoes; in Great Britain, almost three times as large, and with more than four times the population, only 492,217 acres were thus used.

We are glad to hear that the Sheffield corporation have followed in the steps of the corporation of Liverpool, and have adopted the use of Aveling and Porter's 30-ton steam road rollers, for making the streets and roads of Sheffield.

WE learn that Vesuvius continues in about the same state as it has been for the last fortnight—one day the eruption appears on the decline, and the next the smoke and lava issue more abundantly than ever.

A LETTER from Alexandria, dated February 3, reports a disastrous fire three days before, which resulted in the total destruction of one of the largest cotton-pressing and storing establishments at Minet-el-Schiargua.

AN inland revenue return just issued shows that in the financial year 1866-67, no less than 136,978,045 penny stamps were supplied to the public for use on receipts, draughts, and other documents (other than letters) requiring a penny stamp.

THE belief expressed by some geologists that naphtha would be found in the Caucasus has been realized. A boring, 276ft. deep, near Kuaaco, has struck a source of this liquid, which yielded 1,500 barrels daily for one month.

THE Prince of Wales has subscribed £52 10s. to the fund which is being raised in Norwich in connection with the approaching meeting in that city of the British Association for the Advancement of Science. The meeting will commence August 19.

DURING a severe storm that prevailed in Newfoundland for three days lately, it is reported that thirty people have perished from the cold and in the snow. Mr. Mackay, the superintendent of the Newfoundland Telegraph line, nearly perished.

ONE day last week no fewer than 100 railway waggons left Anstruther and the adjoining stations laden with herrings chiefly for the London market. The total quantity was nearly 3,000 crans, making altogether about 3,000,000 herrings brought from the east coast of Scotland.

THE quantity of sugar used in breweries in England is reported to have increased from 9,983,340lb. in the year ending at Michaelmas, 1866, to no less than 39,317,264lb. in the year ending at Michaelmas, 1867. The increase in Scotland was from 209,113lb. in 1866 to 351,456lb. in 1867; and in Ireland from 148,434lb. to 1,465,296lb.

A PARLIAMENTARY paper just issued gives the text of a declaration signed by Sir Augustus Paget and Count Menabrea on behalf of their respective Governments, whereby it is agreed that Italian and English joint-stock companies may exercise all rights and enforce legal proceedings in either country. The declaration is to remain in force until revoked after a year's notice by either party.

THE number of visitors at the South Kensington Museum during the week ending February 22, were:—On Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 10,383; Wednesday, Thursday, and Friday (admission 6d.), from 10 a.m. till 4 p.m., 1,457—total, 11,840. Average of corresponding week in former years, 10,884. Total from the opening of the museum, 7,209,589.

ACCORDING to the "South Australian Register," Mr. Underdown, of Adelaide, the exporter of Australian birds to Europe, has now in stock 35,000 pairs of shell parrots, 1,000 pairs of cockatoo parrots, 7,000 pairs of zebra finches, besides white cockatoos, magpies, and Port Lincoln parrots—altogether nearly 100,000 birds. 9,000 birds are marked as sold. The 70,000 shell parrots are this year's (1867) birds.

THE death has been announced of Mr. William Cory, well known as a coal and ship owner. It was mainly through his exertions, by the establishment of large floating derricks on the river, and the erection of extensive hydraulic machinery, at the Victoria Docks, for quick despatch in the delivery of coal at a low cost, that the trade in coal by sea has of late years been at all enabled to compete with that by railway.

THE effect of trade combinations in driving trade from old localities has of late been frequently alluded to. During the past week a cotton mill in Preston has received a large consignment of spinning machinery from Belgium, which, notwithstanding the cost of transit, has been supplied at 15 per cent. less than the English prices. Once Preston was a noted place for the manufacture of machinery, and it supplied a great part of Lancashire; now its machinery is being actually imported from the Continent.

A CONFERENCE of persons of every class interested in the provision of museums and libraries for the people, together with supporters of our leading social, educational, philanthropic, and religious organizations, will be held, under the auspices of the Public Museums and Free Libraries Association, on the 9th of March, at Sion College, the use of which has been kindly granted for the purpose. The president of the college, the Rev. William Rogers, M.A., canon of St. Paul's, will occupy the chair.

A SECOND collection of artizan's essays on the comparative merits of British and continental industry and manufactures is announced for publication. These essays, to which will be given the prizes offered in connection with the Paris Excursion Committee, will be of special interest as being the best contributions of men actually engaged in handicrafts to the literature of the porcelain and pottery, engineering, cabinet making, gold and silver smith's, tanning, and other trades.

THE golden rose sent this year by the Pope to the Queen of Spain is not, as might be supposed, an object of trifling value; on the contrary, it is a truly remarkable work of art, representing a branch of a rose-tree, with the thorns and buds in pure gold, and having at the extremity a flower of larger size. The bough rests on an elegant pedestal of silver gilt, which bears the Papal arms among its ornaments. The intrinsic value of the present, calculated by the weight of the gold only, is about £400.

THE funeral of the late Mr. William Herapath, F.C.S., took place on Friday last, at Bristol. His remains were interred at Arno's-vale Cemetery, and though the funeral was of a strictly private character, a large crowd of persons assembled around deceased residence, Manor-house, Old-park, to witness the departure of the funeral *cortege*. His name was associated with the analytical departments of chemistry which had most engaged the attention of scientific men during his lifetime, not only in England, but throughout Europe. He was well known, and greatly valued and honoured as one of the professors of chemistry and toxicology in the medical school of Bristol.

A BOSTON paper says that Mr. Charles Francis Adams, Minister to England, is possessor of the largest private library in Boston. It contains 18,000 volumes, and includes those that belonged to his father and grandfather. The late Theodore Parker's library, bequeathed to the Boston Public Library, contained 10,000 valuable, and some of them rare, books. The library of the late Abbott Lawrence (10,000 volumes), has been sold and scattered, as also has been that (7,000 volumes) of Rufus Choate. The libraries of Edward Everett and W. H. Prescott, each containing about 7,000 volumes, have been preserved by their families, as also has that of Daniel Webster, containing 5,000 volumes, chiefly on law. Mr. George Livermore, of Cambridge, is believed to have had the richest library in old Bibles and Biblical works in the world; at his death nearly all his books (4,000) were bequeathed to Harvard University.

THE quantity of unwrought steel exported from the United Kingdom was about maintained last year, the total to November 30 having been 30,517 tons, as compared with 31,529 tons to the corresponding date of 1866, and 20,868 tons to the corresponding date of 1865. The slight decline observable arose in the deliveries to the United States, which only amounted in the first 11 months of 1867 to 17,778 tons, against 18,799 tons in the corresponding period of 1866, and 9,418 tons in the corresponding period of 1865. The total value of the unwrought steel exported to November 30 last year, was £998,619, as compared with £1,029,907 in the corresponding period of 1866, and £686,110 in the corresponding period of 1865. The value of the unwrought steel exported in the whole of 1866 was £1,129,761; in the whole of 1865, £782,129; in the whole of 1864, £890,395; in 1863, £935,517; in 1862, £848,933; in 1861, £726,956; in 1860, £986,228; in 1859, £805,832; in 1858, £589,676; and in 1857, £748,579. The quantities of unwrought steel exported in each of the ten years were as follows:—1857, 22,374 tons; 1858, 16,378 tons; 1859, 24,744 tons; 1860, 32,173 tons; 1861, 21,810 tons; 1862, 25,779 tons; 1863, 28,687 tons; 1864, 26,834 tons; 1865, 23,877 tons; and 1866, 34,647 tons.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgement:—

BOILERS AND FURNACES—2107, 2134, 2182
BUILDINGS AND BUILDING MATERIALS—2128, 2150, 2158
CHEMISTRY AND PHOTOGRAPHY—2121, 2170, 2175, 2198, 2200
CULTIVATION OF THE SOIL, including agricultural implements and machines—2160, 2162, 2176, 2181, 2191
ELECTRICAL APPARATUS—2147, 2192
FIBROUS FABRICS, including machinery for treating fibre, pulp, paper, &c.—2111, 2112, 2117, 2136, 2138, 2140, 2163, 2174
FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—2110, 2122, 2132, 2137
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c.—2145, 2171
GENERAL MACHINERY—2133, 2135, 2144, 2148, 2155, 2164 2177, 2193
LIGHTING, HEATING, AND VENTILATING—2125, 2126, 2130, 2152, 2154, 2157, 2173, 2179, 2180, 2186, 2188, 2194, 2196, 2199
METALS, including apparatus for their manufacture—2114, 2142, 2161, 2166, 2185, 2189
MISCELLANEOUS—2108, 2109, 2113, 2116, 2124, 2127, 2129, 2131, 2139, 2141, 2146, 2151, 2159, 2184, 2187, 2195, 2197
ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—2115, 2119, 2123, 2143, 2149, 2156
SHIPS AND BOATS, including their fittings—2118, 2165, 2178, 2183
STEAM ENGINES—2169
WARFARE—2120, 2153, 2167, 2168, 2172, 2190

2105 W. BARNINGHAM and J. THOMPSON. *Improvements in machinery for bending, straightening, and punching rods, bars, and other articles of metal.* Dated July 18, 1867.

This improved machinery consists of a strong cast-iron bed, supporting the adjustable die holder of the punch and the blocks of the bending and straightening apparatus. An adjustable roller is placed under the centre of the punch, and is so arranged that it can be raised or depressed; the frame for the carrying roller is made with a taper lower edge, which is acted upon by a wedge which is made to slide underneath by a screw furnished with a lock nut. The punch is made of a plain bar of steel fitting in the sliding ram, and it is provided with taper packing pieces to utilize the steel to the greatest possible extent; the sliding ram has a stop motion, so that the punch can be thrown out of action without stopping the machine. The bending or straightening ram is worked by a cylinder attached to the main casting, and a piston and rod to work an ordinary crank shaft, on which is a pinion driving a spur wheel for working an eccentric or crank, and the sliding ram is thus moved alternately backwards and forwards, the stroke or movement of which is adjustable by means of a screw with left hand threads; or the lengthening or shortening of the ram may be effected by water pressure, either by having a head of water at the command of the operator, or by injecting water into either side of the piston or ram; or the stroke may be varied by means of a taper block moved with a screw; or the stroke may be lengthened or shortened by means of an adjustable crank pin, &c. The bar or other article to be bent or straightened is pressed against loose blocks that may be taken out and replaced when worn, or thicker or thinner ones are required.—Patent completed.

2107 T. D. WALKER. *Improved means of heating the feed water supplied to steam boilers.* Dated July 18, 1867.

This invention consists in conducting or forcing the feed water into the boiler through pipes placed along the sides and back end of each furnace or firebox of a steam boiler or steam generator, by which the temperature of the said feed water may be raised to the same, or nearly the same, temperature as the water and steam in the boiler. The discharge end of the feed pipe is connected by a feed valve to the boiler, as usual, and a tap is employed for regulating the supply.—Patent completed.

2108 J., J., and T. PALMER. *Improvements in movable spanners or screw wrenches.* Dated July 18, 1867.

This invention consists in certain improvements in actuating and adjusting the movable jaws of movable spanners or screw wrenches of the kind called Clyburn's spanners or screw wrenches, that is, spanners or screw wrenches in which the movable jaw usually works across the body in a line at right angles, or nearly at right angles, to the handle of the spanner or screw wrench. In actuating the movable jaws of the said spanners or screw wrenches according to this invention the patentees construct and arrange the parts in the following manner:—The bar of the movable jaw works in a recess made across the body of the spanner in the usual way. In the end of the bar of the movable jaw they make a screw box, in which screw box one end of a screw works, the other end of the said screw turning in the body of the spanner immediately under the fixed jaw. A milled collar is fixed by a cross pin or otherwise to the screw. By means of this milled collar the screw may be rotated in one or other direction. A hole is made through the body of the spanner from side to side, in which hole the milled collar is placed and works, the said milled collar being flush, or nearly flush, with the faces of the said body. Instead of placing the milled collar for turning the screw in a hole or recess in the body, one end of the screw may project from the edge of the body, and have a milled head thereon for rotating the screw. By turning the milled collar or head in one or other direction, the screw box of the movable jaw is moved upon the screw in one or other

Digitized by Google

direction, and the movable jaw advanced towards or withdrawn from the fixed jaw on the body of the spanner, and the distance between the two jars is thus adjusted.—Patent completed.

2109 W. WARDEN. *Improvements in securing the more effectual obliteration of postage and other stamps.* Dated July 18, 1867.

This invention consists in preparing the label with a chemical material in the substance of the label itself, and using another chemical material in a more or less colourless obliterating solution, the union of which chemicals will instantly produce a distinct colour, or have a blackening effect, and which effect would not be produced excepting by such union, and, consequently, not of an impervious material, be interposed between the two chemicals, which would be thereby detected.—Patent abandoned.

2110 G. T. BOUSFIELD. *Improvements in heating and cooling apparatus.* (A communication.) Dated July 18, 1867.

This invention is not described apart from the drawings. —Patent completed.

2111 J. J. and E. HARRISON. *Improvements in looms for weaving.* Dated July 18, 1867.

The patentees claim, first, the adaptation of an abutment for the weft fork in connection with the sweel, together with the construction and arrangement of the weft hammer, as described. Second, the construction, adaptation, employment, and use of springs in combination with levers, as described, or any modification thereof, whereby a perfect and even tension is obtained upon the warps. Third, the use of inclined surface discs employed in combination with other arrangements of mechanism for giving tension to the warp, the said inclined surface discs being employed for easing or reducing the tension at any time for purposes required when weaving, as described.—Patent completed.

2112 R. T. BRADBURY and T. BOTTOMLEY. *Improvements in carding engines.* Dated July 18, 1867.

This invention relates to those carding engines in which a "fancy" is employed, situate above the "doffer," and consists in an arrangement whereby the patentees are enabled to arrest small particles or flyings of material and cause them to be conveyed to the doffer. For this purpose they propose to employ two shipping rollers working with each other, the one being in contact with the fancy, and the other with the doffer. The invention is specially adapted to carding engines which are used for wool or other fine fibre in different colours or conditions, for, by its use, the flyings are prevented from being mixed.—Patent completed.

2113 A. PATON. *Improvements in letterpress and lithographic printing machinery.* Dated July 18, 1867.

The arrangement for driving the cylinder of the ordinary printing machine is defective in so far as respects obtaining a good register, since the cylinder will sometimes stop short of a complete rotation, and sometimes go beyond it, according to the speed with which it is driven, and either way a defective register in the printing occurs. To obviate this the patentee arrests, by the action of a brake, the motion of the cylinder (while it is driven by the ordinary gearing), before it has completed its full rotation, and forces it through the remaining part of the rotation by a lever or spring, or both, which will give it a regular and determinate amount of motion.—Patent completed.

2114 J. HARGREAVES. *Improvements in utilizing certain materials or products obtained during the manufacture of steel and iron.* Dated July 19, 1867.

The patentee claims, first, the use of steel slag and steel cinder for the manufacture of glass by means substantially as described. Second, the use of steel slag for the manufacture of carbonates and hydrates of soda or potassa, by means substantially as described.—Patent completed.

2115 J. W. BUTLER and E. EDWARDS. *Improvements in apparatus for floating in and travelling through the air.* Dated July 19, 1867.

This invention consists in making and combining together wings or planes of the kind and in the manner hereinafter described, to which the aeronaut and the propelling apparatus are attached. These wings or planes are made of frames as light and strong as possible, and covered with some strong and sufficiently light material, which, in some cases, the patentees prefer should be flexible, such as cloth, canvas, or varnished silk; and in other cases of thin wood varnished, or of thin metallic plate, either of a single thickness, or double, with a space between for the purpose hereinafter mentioned. It has been found by experiment that such planes, if kept perfectly horizontal and allowed to fall through still air, will do so very slowly, and that even if a certain weight be attached to them proportioned to the number of square feet in their horizontal surface, they will still only fall at a certain speed, which, however great the height of the fall, will not be exceeded. It has also been found that if such horizontal planes with such weights attached to them be made to pass nearly horizontally through the air, but with their front or advancing edges slightly elevated, and if the angle of elevation and speed of horizontal passage through the air be proportioned to the area of such planes, and the weights attached to them, the planes will continue to pass horizontally forward without falling, and that thus, if the propelling force be continued, they may be made to travel for any distance and in any direction.—Patent completed..

2116 J. ROGERS. *Improvements in fastenings.* Dated July 19, 1867.

Here a casing divided into two parts is employed; one part of the casing is fitted with a hook turning on a stud or axis, and furnished with a knob or handle, and the other part of the casing contains a stump, which the hook on the other part of the fastening can be made to embrace or to liberate by turning it on its stud or axis. The form of the casing is a short cylinder closed at the top, and with a flange on its lower edge; it is divided into two unequal parts in a plane parallel to the axis of the cylinder. —Patent abandoned.

2117 J. T. BOUSFIELD. *Improvements in self-lubricating bolsters for spinning machines.* (A communication.) Dated July 19, 1867.

This invention is not described apart from the drawings. —Patent completed.

2118 P. H. METHAM. *An improved rudder, especially adapted for barges.* Dated July 19, 1867.

The object of this improvement is to enable a rudder to occupy greater or less space at the stern, and also to enable it to present greater or less surface as required to the action of the water. For this purpose the inventor forms the rudder of a number of detachable or removable leaves or pieces of different lengths, that is to say, they gradually increase in length from the stern outward. The leaves can be drawn in or out fan-wise.—Patent abandoned.

2119 J. SAXBY. *Improvements in apparatus for locking and actuating the locking and interlocking gear for regulating or governing the action and movement of railway points and signals in relation to each other.* Dated July 20, 1867.

This invention consists in applying to the vertically sliding bolt or stop usually fitted at the front or back of the hand lever used for acting upon railway points, and the signal apparatus of railways, an addition whereby the point or signal lever is secured or held in any prearranged position, whilst certain portions of the locking or interlocking gear may, by the action of the operator's hand on the lever of the sliding bolt, be acted upon so as to lock and unlock such portions of the signal or point apparatus as should be locked or unlocked. We cannot here give space to the details of this invention.—Patent completed.

2120 K. H. CORNISH. *Improvements in entrenching tools, to be carried on the stocks of firearms.* Dated July 20, 1867.

Here the inventor constructs a hand trowel or shovel with a suitable folding or removable handle, the blade of which is so shaped as to be on the butt of the stock of the firearm on which it is intended to be carried, a suitable slot being cut in the wood for the reception of the handle when the entrenching tool is fixed to the stock. When a folding handle is used, it folds over to the upper surface of the blade of the tool which rests on the wood of the stock when the entrenching tool is fastened to the butt. The blade of the trowel is kept in place on the stock by fixed and movable buttons and studs, or in any other suitable manner, the chief desideratum being facility of rapid removal from the stock when required for use. He prefers to shape the point of the blade somewhat after the fashion of a bricklayer's trowel, in order that it may be used for digging, turf cutting, bricklaying, or plastering, as required.—Patent abandoned.

2121 J. HARGREAVES. *Improvements in the production of compounds of soda from chloride of sodium, and compounds of potassa from chloride of potassium, and in apparatus employed therein.* Dated July 20, 1867.

The object of this invention is to produce silicate and aluminate of soda, and silicate and aluminate of potassa. In carrying the invention into operation the inventor makes use of the combustion of hydrogen, or of any mixture of hydrogen with other gases, or any gaseous material containing or capable of evolving hydrogen, or the combustion of any fluid or solid material containing or capable of evolving hydrogen.—Patent abandoned.

2122 T. BROMWICH. *An improved means of allowing the escape of superfluous carbon from casks of newly-made wine, cider, perry, and other fermenting liquors.* Dated July 20, 1867.

The liquid is poured into the cask up to the purge hole, and in the course of two or three days afterwards all the openings in the cask are stopped and made air-tight, with the exception of a hole (about 3-8ths or ½-inch in diameter), which is cut in a convenient part of the barrel, usually at the top. This hole is closed by a boss or knob of leather, india-rubber, gutta-percha, flannel, &c. The boss or knob is caused to be pressed closely down upon the hole by a metallic spring or weight, so that the cask may be completely air-tight. Its effect will, therefore, be to effectually exclude the outer air, but when the liquor inside the cask has generated a certain amount of carbon, the internal force so generated will be sufficient to open the valve, and so allow the surplus carbon from time to time to escape until the liquor inside has ceased to ferment.—Patent abandoned.

2123 C. F. WHITWORTH. *Improvements in apparatus for preventing accidents at junctions, crossings, and sidings of railways.* Dated July 20, 1867.

The specification of this invention is too elaborate to be quoted here at sufficient length for an intelligible abstract.—Patent completed.

2124 A. BUDENBERG. *Improvements in joints of pipes or tubes.* (A communication.) Dated July 20, 1867.

The object here is to obtain a close joint to pipes or tubes capable of being set at various angles. The parts of the pipes or tubes at the junction are of a spherical form, one part of such sphere forming part of one pipe or tube, and the other part forming part of the other pipe or tube. The parts of these spheres where the junction takes place are inclined by preference to an angle of 45deg. with the axis of the parts of the pipe, and are fitted with leather or other packing. These parts are held together by a screw clip, or by other suitable means.—Patent completed.

2125 W. TAYLOR. *Pipes for ventilating, heating, and vaporizing hothouses, malthouses, and other buildings and residences.* Dated July 20, 1867.

The patentee claims, first, the application of chambers or passages to pipes for receiving hot water, &c., so that such chamber or passage may receive water or other liquid to be evaporated whilst they at the same time act as conduit for the passage of air for ventilation, and thereby moisten as well as heat the air so supplied for ventilation, whereby hothouses, malthouses, and other buildings or residences, may be ventilated, heated, and vaporized, as described. Second, the method of forming the joints of pipes used in heating hothouses, malthouses, and other buildings and residences, as described. —Patent completed.

2126 W. G. CREMER. *Improved automatic apparatus for the ventilation of railway carriages, omnibuses, and other vehicles, and the cabins of steamboats.* Dated July 20, 1867.

In performing this invention openings are made in the sides and near the ceiling or roof of the carriage, vehicle, or cabin to be ventilated, and in each of these openings is placed a vertical wicket, such wicket being supported on pivots, so that it can move both backwards and forwards. The outer end of the wicket projects a short distance from the outer side of the carriage, &c., and stands at an angle therewith of about 45deg. When the train, vehicle, or steamboat is in motion, the counter current of air at the sides thereof impinges against the wickets, thus causing a strong and constant exhausting current from the inside of the carriage, &c., vehicle, or cabin outwards. When the direction of transit of the train, boat, &c., is changed, the wickets shift by reason of the counter current of air which comes into operation, and are reversed in position, a similar process of ventilation being thus effected. A door is provided opposite to each of the apertures by which they can, when desired, be entirely closed.—Patent completed.

2127 A. SEZILLE. *An improved process of decorticating, crushing, and treating dry peas.* Dated July 20, 1867.

This invention consists in treating the peas by a moist instead of a dry process, whereby losses are obviated, and the apparatus is rendered inexpensive and easy to work. —Patent abandoned.

2128 R. SHAW and J. STIRK. *Improvements in brick-making machinery.* Dated July 20, 1867.

The object of this invention is to construct bricks by a simple and direct acting apparatus, thereby ensuring a durable machine, as well as one that may be worked economically. The inventors effect this by the use of an ordinary vertical pug mill (for disintegrating the lumps of clay), having at the bottom an aperture of about the size of an ordinary brick, and placed over a suitable rectangular table which sustains a shaft having a double ratchet wheel upon it, and driven by suitable gearing. Between the top of the table and the bottom of the pug mill, a space of the depth, say, of a brick, intervenes to permit the passage of a series of moulds placed across the table. The moulds, although close to each other, are in no way connected, but are successively traversed along the table by the action of the ratchet wheels upon projections on their extremities, and each in turn comes under the aperture in the bottom of the pug mill, receives a charge of clay, and is thrust forward by the one behind it, a drag roller rotating on the top of the moulds keeping each in its place. The brick may then be discharged from the mould by being thrust out through a perforated portion of the table upon an endless band below.—Patent abandoned.

2129 W. POTTS. *Improvements in apparatus for suspending pictures and other articles.* Dated July 20, 1867.

The patentee claims making this apparatus of a rail or foundation of iron, having a close fitting, or nearly close fitting, ornamental covering or casing of brass, or other metal or alloy, or of a non-metallic substance, substantially as described and illustrated, and attaching the said apparatus directly to the wall of the room by means of screws, or by making it engage with staples or screws fixed in the wall of the kind described.—Patent completed.

2130 J. HOOPER. *Improvements in ventilators.* Dated July 20, 1867.

The patentee claims constructing and arranging or combining the parts of a ventilator substantially as described and illustrated, whereby a series of flaps or doors covering a corresponding number of openings in the body of the ventilator may be simultaneously raised or simultaneously lowered, so as to open or close to the required degree the said openings in the ventilator.—Patent completed.

2131 B. P. FRANZONI. *A new or improved method of hardening plaster, plaster castings, and the like.* Dated July 22, 1867.

This invention consists in submitting plaster or materials, or articles made of plaster, such as plaster castings, for the purpose of hardening, and, consequently, of rendering the same more durable, to a bath or solution of glue.—Patent abandoned.

2132 T. A. BRIETHAUPT. *Certain processes of manufacturing extract and essence of hop, to be substituted for the plant itself in the making of beer.* Dated July 22, 1867.

Here the hop extract is a dark brownish product which may present itself under three forms—first, dry and pulverulent; second, soft and thick; third, liquid. It has a very bitter taste, is soluble partly in hot water and partly in alcohol, and serves to give bitterness to beers in their making. Several processes for carrying out the invention are described in the specification.—Patent completed.

2133 H. LEA. *Improvements in taps or valves.* Dated July 22, 1867.

This invention consists in arranging the parts of the tap or valve so that the liquid gas or vapour closes the tap or valve by its pressure on a large area, and opens the tap or valve by its pressure in an opposite direction on a small area when the pressure on the large area has been removed.—Patent completed.

2134 W. R. LAKE. *An improved apparatus for cleaning boiler and other tubes.* (A communication.) Dated July 22, 1867.

This invention consists in the combination of a series of spiral scrapers with movable and stationary heads arranged upon a guide and draught rod, in the combination of one or more elastic or flexible scrapers with the said rod, and in the combination of a coiled spring or equivalent and adjusting nut with the rod and movable head, the whole being constructed and arranged as described.—Patent completed.

2135 J. WALKER. *Improvements in machinery for washing bottles, casks, and other vessels.* Dated July 22, 1867.

We cannot here give space to the details of this invention.—Patent completed.

2136 H. VON S. SAKUNLUNSKI. *Improvements in transferring devices in lace and other fabrics and fac-similes of textures on to printing surfaces, and in the application of the devices and textures obtained from such surfaces.* Dated July 22, 1867.

The object of this invention is to produce, by the aid of the printing process, representations of reticulated ornamental fabrics, and fac similes of texture, for the purpose of ornamenting fabrics used for furniture or dresses, and for producing illustrations for pattern and other books.—Patent abandoned.

2137 W. E. NEWTON. *Improvements in brewing.* (A communication.) Dated July 22, 1867.

The object of this invention is to so treat the hops, and to so construct the vessel in which they are placed, that, when the beer is added to the hops, the whole aroma of the hops will be extracted by the beer and retained therein. —Patent completed.

2138 D. WELSH. *Improvements in looms for weaving.* Dated July 22, 1867.

We cannot here give space to the details of this invention.—Patent abandoned.

2139 E. TOMLINSON. *Improvements in ornamenting, printing, colouring, enamelling, staining, cutting, creasing, bending, and manufacturing articles from wood and other material.* Dated July 23, 1867.

This invention has for its object improvements in printing or placing designs or labels on wood, card, paper,

Digitized by Google

metals, and particularly on wood and scale board, for match or other boxes, which are printed or stamped and cut through at one operation, and for boxes creased and bent, the whole being the result of the same combined action. This is accomplished by placing knives, cutters, or rules made of any suitable material in combination with the printing press, or any suitable machine (either cylindrical or flat pressure), that is, the knives or cutters are fixed in the required position in the forme, or that part that receives the pressure resulting from the action of printing, so that the wood, card, paper, or other material is first cut through and then stamped or printed, and with boxes creased or bent, the whole being the result of the same combined action; or in some cases to perform one or more of the said operations at one and the same time.—Patent abandoned.

2140 J. H. JOHNSON. *Improvements in the manufacture of nets and netting.* (A communication.) Dated July 23, 1867.

The essential feature of this invention consists in using one-half of the twines or cords or every alternate one of the full size that would be used if the netting were made in the usual way, whilst the other half of the rest of the twines consist of a single strand of the full sized twines when that twine has three strands, and two strands when the full sized twine has six strands, and so on, that proportion giving an equality in strength and proper appearance to the netting, but other proportions may be used.—Patent completed.

2141 W. DENNIS. *Improvements in letter boxes, letter pillars, and such like depositories.* Dated July 23, 1867.

This invention consists in constructing the box with or without a fan wheel at the aperture, and dividing the box at about the centre thereof with two pieces of metal of a triangular form, somewhat similar to the letter V, and either with or without a flap joint near the point thereof; the flap joint may be shut by a hinge and made to balance and close of itself after a letter in its descent has pushed it open and passed through into the bottom of the box.—Patent abandoned.

2142 H. A. DUFRENE. *Improvements in preserving iron from oxidation.* (A communication.) Dated July 23, 1867.

This invention consists in covering the surface of the iron to be protected from oxidation with a coat of brass—that is to say, with a coat of an alloy of copper and zinc.—Patent completed.

2143 W. EASTERBROOK. *Improvements in machinery or apparatus for actuating, setting in motion, locking, interlocking, and controlling railway points and signals.* Dated July 23, 1867.

This invention relates to a former patent, dated 29th March, 1867 (No. 927), and consists in the introduction and use of two rods, instead of one rod, parallel to and connected with the main lever, and worked by a spring handle, and both rods extended to a sufficient distance below the top plate, and then flattened or widened as required, and there such rods, instead of the main lever, are securely locked, so that by means of notched plates and stops on the main lever, when such rods shall have been lifted, certain bars are made to slide, and the conflicting rods are instantly and firmly locked down in their respective notches before the lever itself is moved or pulled over. The object of this system is the better securing of the opening and shutting of points and regulating signals.—Patent completed.

2144 J. MARLEY. *Improved apparatus for the prevention of overwinding and falling of the cages used in mine shafts, lifts, and hoists.* Dated July 23, 1867.

In order to prevent the overwinding of the cage, independently of the detaching hook when the cage bottom is drawn beyond the safe point of the "settle board," a catch is actuated by suitable mechanism, such as is well understood, shuts off the steam from the engine, and applies it to a powerful steam brake. In passing the before-mentioned safe point the cage enters "conductors" which are gradually contracted towards the top, so as to have the effect of stopping the cage. The conductors rest at their upper parts either against springs or weights, in such a way as to admit of their opening out to some extent, and thus effect the purpose of preventing the cage being stopped too suddenly. A safety chamber is provided, which consists of boxes either close or grated, when necessary, corresponding with the size of the cage which is drawn into the chamber. This arrangement prevents the men from either falling or leaping out of the chamber when the cage is drawn into the boxes, and which latter extend in height from the bottom of the before-mentioned conductors to their top at the safety buffers. In order to prevent the cage from falling out of this chamber through the breakage of the rope, even if a safety cage be used, a series of catches or "heps" is placed within the same. The safety table is placed immediately under the ordinary heps, and covers the whole of the working shaft by the closing of two tables or trucks over the same. When the cage reaches a catch placed near the top of the safety chamber, the mechanism is actuated, by which the safety tables or trucks are released and run down an incline so as to close over the shaft.—Patent abandoned.

2145 S. BONSALL. *Improvements in spring bed bottoms.* Dated July 23, 1867.

This invention cannot be fully described without reference to the drawings.—Patent completed.

2146 S. BONSALL. *Improvements in tanning, and in the machinery and apparatus to be employed therein.* Dated July 23, 1867.

The patentee claims, first, hanging the hides in a vat, and agitating the tanning liquid by means of a rotary dasher or agitator, substantially as described. Second, placing the dasher or agitator entirely in the inside of an ordinary pit or vat. Third, hanging the hides in a close water-tight vat, and agitating the tanning liquor by a rotary or otherwise moving dasher, while the liquor is under pressure within the closed vat, substantially as described. Fourth, the combination of the water-tight vat, the dasher, and a force pump, or other equivalent means of producing pressure within the vat, and the stop-cock arrangement for retaining the pressure, substantially as described. Fifth, the dasher described located in the lower portion of the vat in combination with the bars described, or other equivalent means of hanging, suspending, or supporting the hides in the vat either above or below the dasher, so that the tanning liquid when agitated by the dasher will freely permeate between the hides, substantially as specified.—Patent completed.

2147 SIR W. THOMSON. *Improvements in receiving or recording instruments for electric telegraphs.* Dated July 23, 1867.

This invention has more especially for its object to produce an instrument capable of recording by permanent marks such electric signals as have up to the present time been received by the mirror galvanometer, as described in the specification of a patent granted to the patentee February 20, 1858 (No. 329). The peculiar merit of that instrument is that it continuously indicates with approximate exactitude the variations of strength in the received current, the movement of the spot of light follows every variation in that current, and these varying strengths being followed by the eye can be interpreted under circumstances in which ordinary instruments indicating the mere presence or absence of a given strength of current would be useless. By these improvements the patentee is enabled to construct an instrument which draws or marks on a strip of paper a curved or broken line, giving a graphic representation of the varying strength of current, or, if required, of electric polarity, at the receiving end of the cable, and gives a permanent record of every feature of the effect due to the sender's action.—Patent completed.

2148 W. GEEVES. *Improvements in machinery for cutting tenons.* Dated July 23, 1867.

According to this invention the patentee arranges tenon cutting machinery to produce two tenons simultaneously one at each end of a bar or piece of wood at any required distance the one from the other, and so that, without any setting out of the work on the bars or pieces of wood, any number of them may be tenoned at each end to exactly the same length.—Patent completed.

2149 R. LAKIN. *Improvements in aerial locomotion.* Dated July 24, 1867.

The object here is to carry passengers or goods in suspended vehicles attached to wire or other ropes, supported upon strong elevated columns of masonry and ironwork combined. These columns must be sufficiently high to allow the vehicles to pass over the tops of houses or other buildings, instead of running on the ordinary roads or streets.—Patent abandoned.

2150 W. SIMPSON and W. HOWITT. *Improvements in the construction of the roofs of horticultural and other buildings and structures.* Dated July 24, 1867.

The patentees claim constructing the principles of the roofs of horticultural and other buildings and structures hollow instead of solid, and of tubes or pipes and sockets, either separately or in combination, with longitudinal pipes, rods, or bars, as described.—Patent completed.

2151 W. BETTS. *Improvements in the manufacture of capsules.* (A communication.) Dated July 24, 1867.

This invention relates to colouring metallic capsules for bottles, &c., whereby the coloured capsule has the appearance of being coated with sealing-wax, whilst at the same time such coating is capable of resisting the bending and friction necessary for the application of the capsule to a bottle. A white elastic varnish, known as "sochuée, is used.—Patent completed.

2152 H. AITKEN. *Improvements in the manufacture of coke.* Dated July 24, 1867.

Here retorts are used which are situated at an angle of 25deg. to the horizon, but which may be placed at any other angle from the horizontal to the perpendicular. The upper and lower ends of the retorts are wider and deeper at the bottom than the top, and taper gradually from the bottom to the top. The retorts are provided with lids or doors, the bottom lid or door being made the full size of the retort; the top lid or door may be made smaller than the retort, if desired. The retort is charged from the upper end with the coal or slack from which the coke is to be made, and suitable space left for expansion. Suitable pipes, condensers, and holders are employed for taking off and receiving the liquid and gaseous products of the distillation, and the inflammable part of the gas is conducted below the retort, and there used as the fuel by which the temperature for the distillation and conversion is effected, or chiefly effected.—Patent abandoned.

2153 R. B. RODEN. *Improvements in breech-loading fire-arms.* Dated July 24, 1867.

These improvements, whilst they are applicable to all systems having vertical faced breech-blocks, are more especially intended as further improvements upon the inventions for which letters patent were granted as follows:—No. 1828, year 1862, to F. E. Schneider and J. Snider, jun.; No. 2145, year 1864, to T. Wilson; No. 2741, year 1864, to J. Snider, jun.; No. 2912, year 1864, to J. Snider, jun.; No. 188, year 1865, to J. Snider, jun.; No. 2275, year 1865, to J. Snider, jun., and consists of the following arrangements:—Instead of placing the lock on the side of the stock, as now generally practised, it is inserted in the middle of the same, and directly over or in connection with the trigger guard, which may or may not be modified to suit the particular form or construction of lock. The lock may be of any suitable construction, and so arranged as to operate or function a striker or bolt, which can be used either for percussing the piston or striker which produces the ignition of the cartridge, or for holding the breech-block against accidental explosion, or both. Instead of the ordinary dog or hammer a lever thumb-piece is used by which the striking or locking bolt is retracted after the discharge of the arm. The breech tang and tail pin are also modified so as to clear the mechanism of the lock. These improvements further extend to a method of and in arrangements for extracting the expended cartridge case, whether such extractor be operated in connection with the breech-block or otherwise. This is effected by arranging the extractor and its bed so as to operate on the rim of the cartridge case at or a little below its diameter, the diameter corresponding with the horizontal axis of the barrel, and by forming or placing an inclined plane on the bed of the shoe, either elastic or otherwise, by which means the cartridge case may readily be ejected from the shoe. In the case of existing arms a stud or stop is placed in the shoe at any suitable point, and by drawing back the extractor sharply when the head or rim of the cartridge comes in contact with such stud or stop, it will cause the case to fly out in a similar manner. This stud or stop may be made rigid or elastic. The said invention further consists in constructing a ridge or flange on the underside of the breech-block, which ridge or flange fits into a corresponding groove in the bed of the shoe, its object being to retard any escape of gas backwards in case of the bursting of a cartridge on explosion, but this is only used in the absence of a locking bolt.—Patent completed.

2154 T. PRIDEAUX. *Improvements in open fireplaces and stove-grates, for the purpose of economizing fuel and securing a more perfect combustion.* Dated July 24, 1867.

Here the inventor constructs in the chimney of the fireplace, or other convenient place, a tube or flue open at end to the external atmosphere, or to the atmosphere of the room or building in which the fireplace is situated, and at the other end communicating with a chamber constructed at the back or sides, or back and sides of the fireplace, the chamber being provided with a grating or perforated plate at the part next the fire; air thus passes into the tube or flue at the open end, and thence into the chamber, being heated in such passage and issuing through the grating or perforations into the fireplace among and above the burning fuel, thereby effecting a material saving of fuel and a more perfect combustion.—Patent abandoned.

2155 A. M. CLARK. *An improved reciprocating motion.* (A communication.) Dated July 24, 1867.

This invention relates to a new and improved reciprocatng motion for engines and other purposes. Its object is to convert a reciprocating motion into a rotary, or a rotary into a reciprocating motion, without the use of the crank, thereby avoiding the two dead points at each revolution with less strain and wear of the parts. It consists in the employment of a pinion or toothed wheel, working in a double or top and bottom rack, and of an inner and outer cam to relieve the dead joints.—Patent completed.

2156 S. TURTON. *Improvements in apparatus for facilitating communications between passengers, guards, and drivers of railway trains.* Dated July 25, 1867.

In one or more compartments of every carriage composing the train is placed one or more handles, which are connected to, or form part of a drop rod which, when the handle is moved, acts on a catch, and liberates a weighted lever or arm which fits on a rod extending the whole length of the carriage. The extreme end or ends of the rod are taken into the guard's van, or to the engine, or to both, and connected to a bell, whistle, or other alarum As soon as one of the levers above referred to has liberated the catch, the weighted lever or arm in falling turns or partially turns a longitudinal rod extending from end to end of the carriage; the ends of these rods are connected by a self-acting universal coupling. The position of the weighted arm and handle will indicate the compartment and the carriage in which the signal has been given for calling the attention of the guard.—Patent completed.

2157 W. HOWES and W. BURLEY. *An apparatus for securing lamps for railway and other carriages.* Dated July 25, 1867.

This invention consists, first, in forming on the side of the lamp next to the carriage a tapered socket, open at the bottom and closed at the top, where a female thumb-screw is fitted; the screw is free to turn horizontally, but is screwed in position vertically by having a groove cut round the neck, into which groove the end of the pin, passing through the side of the collar at the top of the socket, enters. Second, in forming a lamp iron (fixed to the carriage) with a stem made to fit the socket above mentioned; at the top of which stem there is a small screw, the end of which, when the lamp is placed upon the iron, enters the female on the thumb-screw, upon turning which the lamp will be firmly secured. When removing the lamp, the thumb-screw and taper form of the socket facilitate the lifting of the lamp, and prevent it from getting fixed or jammed upon the stem.—Patent completed.

2158 C. H. MURRAY. *Improvements in machinery for moulding clay for making bricks, tiles, and other analogous articles from plastic substances.* Dated July 25 1867.

This invention consists in constructing the dies or apertures in brick-making machines through which the plastic material is delivered with movable hollow boxes or vessels provided with perforated sides, and supplied with any suitable lubricant, which, by exuding through the perforations in the boxes, will lubricate the desired parts.—Patent completed.

2159 C. T. MOULAN. *Improvements in the construction of movable joints for connecting metallic pipes and tubes.* Dated July 25, 1867.

The object here is to connect together iron tubes, such as are used for gas or water. To this end a small shoulder is cast on the outside, and near the end of each of the tubes a cast iron ring is then slipped on over the joint where the tubes are to be connected, and on either side of this ring are placed vulcanized india-rubber washers, which are firmly pressed against the ring by means of concave sockets provided with ears, whereby they are strongly bolted together by screw bolts, and by tightly screwing up these sockets leakage will be effectually prevented.—Patent abandoned.

2160 W. E. NEWTON. *Improvements in the construction of mould boards for ploughs.* (A communication.) Dated July 25, 1867.

This invention consists in making the mould boards of ploughs of such a shape that the grade of the board will be a true inclined plane from the point to the extreme end of the wing, where the greatest height of the plane terminates at a point from the ground equal to the width of this plough, which may be supposed to be one foot.—Patent completed.

2161 A. WILSON. *Improvements in the casting of ingots.* Dated July 25, 1867.

This invention consists in placing the ingot mould upon the table of a weighing machine supported by a steel yard or weighted levers, or suspended from a spring balance. The ingot mould and everything in connection with it is then weighted. By adding the weight of the ingot to be cast to the weight of the ingot mould and its accessories, the patentee is enabled to make the ingot of any given and desired weight.—Patent completed.

2162 J. BROWN and W. LILLIE. *Improvements in reaping and mowing machines.* Dated July 25, 1867.

This invention consists in employing two wheels, either bevel or spur wheels, of different diameters on the first driving shaft, which may be cast in one piece, or may be made separate; these wheels are fitted to slide endwise simultaneously upon the shaft on which they are carried; or they may be keyed fast on the shaft, the shaft being arranged to move endwise in its bearings to enable the wheel or wheels to gear into one of two pinions, which may either be cast in one piece, or separately, and are carried on the intermediate shaft.—Patent completed.

2163 W. WOOD. *Improvements in producing and treating fibres from rags, and in apparatus for the same.* Dated July 25, 1867.

An important feature in this invention consists in

Digitized by Google

evenly distributing upon the rags an excess of the oil or lubricant ordinarily employed, instead of merely sprinkling it thereon, as usual.—Patent abandoned.

2164 A. MACKIE. *Certain improvements in the method of composing and distributing type, and in apparatus to be employed for such purposes.* Dated July 25, 1867.

This invention is designed for the purpose of setting or "composing" a duplicate or multiplied number of columns of type of the same matter simultaneously, which is useful for special purposes, and where a reproduction of the same information is required in type. The improved method of setting the type consists in placing the letters in transverse lines (each line being a row or series of same letter), and one line above another in layers, so that when all the type is "set," if the block of type so formed be "sliced" at right angles to the layers, the line of type removed by each "slicing" forms a perfect column of legible matter.—Patent completed.

2165 T. M. ALMOND. *Improvements in signalling at sea, and in apparatus to be employed for such purpose.* Dated July 25, 1867.

Here the inventor furnishes each vessel with two signal lanterns placed in a vertical line, one about three feet (more or less) above the other on a small spar supported in a socket or bracket at any convenient place in a conspicuous part of the vessel. These lanterns have shutters, and red and green glasses, and are kept darkened by means of the shutters when not required for signalling. As soon as a vessel is sighted, the signalman uncovers the lanterns and shows two white lights (one above the other) to signal to the vessel that she has been seen, turning the spar slightly in the socket (if necessary) so as to direct the light towards the ship. So long as the vessel holds on her original course the white lights are shown, but the instant that the person in charge gives the word "port" or "starboard" to the helmsman, the signalman shows two red or two green lights to indicate to the other vessel the change of course adopted.—Patent abandoned.

2166 C. E. BROOMAN. *Improvements in the manufacture of cast steel and its derivatives.* (A communication.) Dated July 25, 1867.

The patentee claims the manufacture at one continuous operation on the sole of a reverberatory furnace heated by gas of four kinds of cast metal, viz., hard steel, soft steel, cast iron (fer fondre), and mixed metal, by the simple variation of the doses, this continuous process comprising three features—first, the original bath of casting; second, the refining in excess by the addition of iron or ore; and, third, the return of the bath to the desired point by adding a fresh quantity of casting, and the process being based on the high temperature of the metallic bath, and on the carburation and decarburation of the metallic bath, all as described. Second, the refining of the casting directly by the chemical action of oxide of iron, as described, without any injection of air or steam. Third, the fusion of a casting in a liquid bath, the surface of which is preserved from oxidation by a gaseous layer always reductive, as described. Fourth, the manufacture of cast steel and its derivatives on the sole of a furnace, below which is an empty space for cooling it, as described. Fifth, the decarburation of the casting in presence of solid matters which will absorb the carbon, such as ores and metals of iron and steel under the simple action of a very high heat (2900 to 3650deg. Fah.), as described. Sixth, regulating the decarburation and the recarburation of the bath by varying the work of the furnace, and the dosing of the materials, according to the quality of steel or metal to be produced, as described.—Patent completed.

2167 C. E. BROOMAN. *Improvements in the manufacture of cartridge cases.* (A communication.) Dated July 25, 1867.

Here the inventor makes the interior of the case of paper, pasteboard, cloth, or other suitable material, and the exterior of brass, iron, steel, zinc, or other metal or alloy; as the inner tube has a certain rigidity, the outer metallic tube may thus be made very thin.—Patent completed.

2168 G. L. BARENS and J. F. LADOUGNE. *Improvements in breech-loading firearms and in cartridges.* Dated July 25, 1867.

This invention consists, first, in a breech-piece having the cap and the other for the cartridge; this breech-piece also acts as a cartridge extractor, and permits of regulating the carrying power of the gun; at the same time, it prevents all escape of gas, and gives more security for the fire. The invention also consists in a new action to tilt and secure the barrels or barrel.—Patent completed.

2169 J. EDGE. *Improvements in steam engines.* Dated July 26, 1867.

This invention relates to the "slide valves" used to regulate the admission and discharge of the steam to and from the cylinders of steam engines, and to the "governors" employed to control the speed of the engines, and consists, in so far as relates to the "slide valves," of a novel method of actuating the said valves, applicable, principally, to engines working expansively. In carrying the invention into effect the patentee employs two separate valves for the admission of the steam to the cylinder, and two for the discharge thereof, or for opening a communication between the cylinder and the condenser. These aforesaid valves are preferably of the description known as "gridiron" valves, or of a form similar thereto, the valve boxes being situated as near the ends of the cylinder as is convenient for the purpose of obtaining short passages between the valves and the interior of the cylinder, but they may be otherwise situated. The valves are actuated by "cams" or "tappets" fitted on a "shaft," or on "shafts" to which a rotary motion is imparted by the engine, the said shaft or shafts revolving at one-half the speed of the "crank shaft" of the engine. The valve spindles are preferably furnished each with two "bowls" for the cam to act upon, and with a suitable frame to carry the same, each cam being so formed as to give two movements to the valve which it actuates during one revolution of the cam, the movements being similar to each other, but in opposite directions, so that, taking for example the inlet valve admitting steam for the forward stroke of the "piston," the said valve is moved by its cam in one direction to admit the steam to the cylinder for a forward stroke, and back again to its former position to admit steam for the next succeeding forward stroke, each movement admitting the steam for a suitable portion of the stroke, and "cutting off" the said admission at, or nearly at, any desired portion of the stroke. The "cams" actuating the "inlet valves" may be stepped or otherwise formed or arranged for altering the "cut off." The valves may be actuated by separate shafts, or one shaft may actuate two or more valves. The improvements in the "governors" of steam engines are as follows:—On a shaft or stud a ratchet wheel is mounted, having one half, or other suitable proportion, of its teeth pointing in a contrary direction to the remaining portion; or two separate wheels or segments, with the teeth of each one reversed as compared with the other, may be employed. An arm or lever carrying two pawls, and having a reciprocating motion derived from the engine, is mounted on the same centre of motion as the above described "ratchet wheel," the aforesaid "pawls" acting in opposite directions on the teeth of the "ratchet wheel," and being kept out of action when the engine is running at its proper speed by a curved guard which is interposed between the pawls and the "ratchet teeth," the guard being moved around the ratchet wheel by a rod or other connection which is actuated by the sliding "sleeve" of the governor, so that as the sleeve rises or falls with the varying speed of the governor, one or other of the "pawls" is allowed to act upon the ratchet teeth, and the ratchet wheel is rotated, the movement of the ratchet wheel being employed to move the inlet cams, as before described, for altering the "cut off." There are other features which we cannot produce here.—Patent completed.

2170 C. SILVY. *Improvements in photographic apparatus (photographic cartridge.)* Dated July 26, 1867.

This invention relates to apparatus which, on being combined with the camera obscura now used in photographic apparatus, allows, by suppressing the ordinary frames and dispensing with dark tents, of taking panoramic views on all points of the horizon.—Patent completed.

2171 R. REID and E. H. CRAIGIE. *An improved reclining chair.* Dated July 26, 1867.

This invention is not described apart from the drawings.—Patent completed.

2172 G. B. NORTHCOTE. *Improvements in apparatus for charging and turning cartridges for breech-loading firearms.* Dated July 26, 1867.

This apparatus consists of four bags or holders containing respectively the powder for the charges, the shot, the wads to be placed in the cartridge cases between the powder and the shot, and the wads to be placed in the cartridge cases over the shot. Beneath these bags or holders there is a slide acting to measure the powder and the shot, and to cause the escape of the wads one at a time from the wad bags or holders. Underneath this slide is a bed plate forming part of the frame of the apparatus, and in this plate there are two, or it may be three, passages, one passing vertically or direct through it, and having the cartridge case to be charged immediately beneath, the other or others passing in an oblique direction, so as also to lead into the cartridge case. Over the first hole a rammer is mounted; it can be depressed by the hand of the operator to force down the wads into the cartridge cases, and it is brought up again by a spring. The stem of the rammer may pass through a frame which is able to move it for a part of its stroke; this frame carries spring blades which enter the cartridge case, and open it out should it require it to ensure the wads entering truly. The cartridge case may be held in a tube which is mounted on axes, so that after receiving its charge, it can be turned partly round, so as to bring the mouth of the cartridge case opposite a closing or turning apparatus. The operation of the apparatus will be obvious to those familiar with the subjects.—Patent completed.

2173 E. SMITH. *Improvements in gas regulators.* Dated July 26, 1867.

The object here is to regulate the supply of gas as it issues from the main to the burner, in order to prevent variation in the size of the flame, notwithstanding any difference that may occur in the pressure of the gas in the main. An additional illuminating power is also given to the light by means of a reflector, all as described. The invention primarily consists in placing the passage for the gas inside the regulator; a valve is placed in the base of the regulator, the upper end of which is weighted according to the quantity of gas to be consumed per hour, and connected to a diaphragm, formed by preference of leather made from goat's skin; the space between the diaphragm and the base of the regulator forms a chamber for the reception of gas from the supply pipe which it enters by the valve; the pipe for conveying the gas from this chamber to the burner leading into the same, a reflector of silvered glass is placed round the tube leading to the burner; it is screwed or fixed at top to a metal cap holding the burner, which latter the inventor makes, by preference, of lava or steatite, and at bottom it fits into the chamber containing the diaphragm, which latter chamber is made of "Britannia" metal.—Patent completed.

2174 J. SMITH and W. SCHOFIELD. *Improvements in the construction of elastic rollers for squeezing yarns and fabrics, and for other purposes.* Dated July 27, 1867.

This invention consists in making rollers with an elastic surface composed of rings, washers, or spiral bands of india-rubber, or any suitable compound of india-rubber.—Patent completed.

2175 E. A. RIPPINGILLE. *Improvements in the mode of distilling or separating the more volatile portions of petroleum and other mineral oils, and in means or apparatus for ascertaining the igniting and explosive point of such oils.* Dated July 27, 1867.

This invention consists, chiefly, in the employment of a jet or jets of steam to draw or force in a current or currents of air through the petroleum or other mineral oil from which it is desired to separate the more volatile portions, such jets acting in a somewhat similar manner to the blast of a locomotive engine.—Patent completed.

2176 T. REID. *Improvements in agricultural implements for digging potatoes, for grubbing, for forming drills, and for similar uses.* Dated July 27, 1867.

This invention consists in adapting or adding to a frame like that of a double-moulded plough, firstly, a small single share in front running on the surface, and serving to turn over to one side the "shaws" or above-ground part of the potato plant; and, secondly, a coulter to divide the earth placed a little behind the surface share, and having a mould board fixed to it to continue the turning over action on the shaws; and, thirdly, two or three pairs of knives fixed to the sole of the plough-frame to detach and throw out the potatoes, the front pair of such knives being in about the position of the ordinary share, and united in front, but diverging behind, outwards, and slightly upwards, whilst the other pair or pairs of knives is or are similarly placed further back, and are longer, the hindmost being the longest.—Patent abandoned.

2177 W. E. GEDGE. *An improved machine for cutting slate in quarries previous to laying them open, and for cutting in coal-pits, mines, and stone quarries.* (A communicaton.) Dated July 27, 1867.

This invention is not described apart from the drawings.—Patent completed.

2178 E. T. HUGHES. *Improvements in the mode of constructing and propelling steam vessels.* (A communication.) Dated July 27, 1867.

The object here is to decrease the weight and draught of water of steam vessels, and, consequently, the resistance to their rapid motion; and also to increase and make more available the effective power by which they are driven, while at the same time the patentee makes them stronger and less liable to sink or become disabled. The invention consists, first, in applying the power to drive the paddle-wheels of a side-wheel steamer to the paddle-wheels at or near the peripheries by gearing teeth or cogs on or near their peripheries, into which the teeth of a driving wheel (which is itself driven by a suitable engine) engage. Second, in constructing the driving wheel in two parts, viz., a rim on which the teeth are formed, and a central body or driving portion, and inserting between the body and rim india-rubber, or some other elastic non-resonant body. Third, in applying heat to the gearing on the peripheries of the paddle-wheels (when it is necessary to do so to melt ice which may accumulate thereon) by steam introduced into pipes set into or upon the wheels for that purpose. Fourth, in combination with the application of the power for driving the vessel as above stated, constructing and supporting the hull of the vessel with transverse walls at frequent intervals (the walls being securely fastened to the sides and bottom of the vessel, and connected together by means of a web at or near their tips), and without ribs, thereby gaining great strength with comparatively small weight of materials.—Patent completed.

2179 W. E. NEWTON. *An improved water and gas meter.* (A communication.) Dated July 27, 1867.

This invention is not described apart from the drawings.—Patent completed.

2180 P. A. ROHART. *Improvements in the manufacture of gases for the production of light, heat, and motive power, and in apparatus for that purpose.* Dated July 27, 1867.

This invention is not described apart from the drawings.—Patent completed.

2181 A. JACK. *Improvements in machinery or apparatus for digging potatoes, turnips, and other roots.* Dated July 27, 1867.

Here a framework of iron is employed, which is supported on wheels, so that it may be dragged over the surface of the field out of which the roots have to be dug. The attendant follows behind the digging apparatus, and at the place where he is situated the handle of a lever is placed. The lever is jointed to the main framing, and its opposite end is attached to a frame placed below it. The frame carries the digging or root-raising apparatus, which consists of a grated or gridiron plate; this is situated at an angle with the plane of the field from which the roots are to be raised, so that as it is drawn over the ground the root-raising plate may enter the surface of the ground in such manner that its lower edge descends below the level of the underside of the roots which are to be raised. The use of the lever before referred to is to adjust the elevation or depression of the root-raising plate below the surface of the ground. One of the large wheels which carry the apparatus has a circular toothed ring fixed on to it, the teeth of which gear into, and, when the apparatus is in motion, actuate a pinion on a cross shaft, to which a series of arms is fixed; these arms revolve in proximity to the root-raising plate, and as they revolve their effect is to separate and throw back on the surface of the dug ground the roots that have been raised on to the plate. This last operation cleanses and separates the roots from the earth or soil in which they have been embedded, and the cleaning action may be further improved by attaching chain harrows to the back of the apparatus, which, in passing over the roots, rub them still cleaner.—Patent abandoned.

2182 H. CHAMBERLAIN. *Improvements in hot blast stoves.* Dated July 27, 1867.

This invention has reference, partly to ordinary hot blast stoves, and partly to a novel construction and arrangement of hot blast stove. One of the essential features of the invention consists in packing the flues or spaces between and amongst the blast pipes or passages of ordinary hot blast stoves, or of hot blast stoves of this improved construction, with open brickwork, so disposed as not materially to interfere with the draught, whilst they act as magazines or storers of heat by becoming highly heated throughout the entire length or area of the heating chamber or space, and when so heated will radiate a uniform or nearly uniform degree of heat.—Patent completed.

2183 G. FRANKLIN. *Improvements applicable to ships' compasses.* Dated July 27, 1867.

In constructing steering compasses the inventor employs an inverted card, that is to say, a compass card with the points marked upon it on the under side. Below the card, and in front of it, he mounts an inclined mirror, so as to reflect the light from the card to the eye of the steersman, who, looking in the direction of the mirror, sees an image of the card in a vertical or nearly vertical position, with the point which marks the direction of the ship's head uppermost. The card is lighted by means of side glasses which at night have lamps set in front of them. The inclination of the mirror is made adjustable, so that the instrument may be set to suit any distance from the wheel at which it may be placed.—Patent abandoned.

2184 T. JONES. *Improvements in locks and latches.* Dated July 27, 1867.

This invention consists of the addition of the mechanism hereinafter explained to locks and latches having spring bolts with bevelled ends, which mechanism has for its object to prevent the bolt of the lock or latch being forced back by pressure applied to its end. The invention, as applied to a spring latch having a barrel lock, is as follows:—Immediately over the bolt is a lever turning upon a pin in the latch case. This lever is pressed upon by a spring, that end of the spring which presses on the lever being of a V or convex shape, and bearing upon a projection on the lever immediately over the pin on which it turns. The projection is also of a V or convex shape. On the barrel of the lock is a projecting piece which, on turning the barrel, comes against a projection on the

Digitized by Google

under side of the lever, and raises the long arm of the lever, or that end of the lever turned towards the bevelled end of the bolt. The lever remains in the raised position during the further motion of the barrel and the withdrawal of the bolt. After the opening of the door and the withdrawal of the key the lever retains its raised position until the closing of the door, when the forcing back of the bolt causes a shoulder on its inner end to strike against the tail of the lever, and depress the long arm of the lever, causing it to engage at the back of the head of the bolt, and to prevent the motion of the bolt inwards. The bolt cannot now be forced back by the insertion of a tool or instrument between the door and door frame. The introduction and turning of the key effects the raising of the lever and the liberation of the bolt in the manner before described. The lever is retained in one or other of the positions described by the V-shaped end of the spring pressing upon one or other side of the centre of the V-shaped projection over the axis of the lever. In order to enable a person inside the room to liberate the latch bolt without the use of the key, a small knob outside the latch case may be connected through a slot in the latch case with the lever. By means of this knob the lever may be raised and the bolt liberated.—Patent completed.

2185 J. WOOD. *Improvements in the manufacture and treatment of certain kinds of iron.* Dated July 27, 1867.

In making cast iron capable of being annealed, according to this invention the inventor takes hematite pig iron, and to one part by weight thereof he adds from one-third of a part to one part by weight of scrap steel, or wrought iron, and he melts the mixture together in a crucible or cupola. The larger the proportion of steel or wrought iron the stronger and the tougher will the resulting cast iron be. The cast iron made in the manner described is cast in the usual way. In annealing cast iron made in the manner described he uses powdered charcoal, and he effects the annealing in the usual way, excepting that he heats the cast articles in the powdered charcoal, or subjects them to the annealing process during a much shorter time than when the annealing is effected by the use of hematite or Cumberland ore, as is usual.—Patent abandoned.

2187 A. MACFIE. *Improvements in apparatus for supporting lines for drying clothes, and for other like purposes.* Dated July 27, 1867.

This invention consists of apparatus for supporting lines for drying clothes, &c., whereby the line can be easily lowered, and easily brought again into and fixed in its raised position. The details of the invention are too voluminous for insertion here.—Patent abandoned.

PROVISIONAL PROTECTIONS.

Dated October 10, 1867.

2846 C. Avery, Little Cross-street, Islington. Improvements in breech-loading firearms.

Dated October 12, 1867.

2877 J. H. Johnson, Lincoln's Inn-fields. Improvements in knitting machines. (A communication.)

Dated January 18, 1868.

177 J. Whiteley, Huddersfield. Improvements in twining jennies, or apparatus for twining or doubling cotton, silk, worsted, and other fibrous substances.

Dated January 22, 1868.

222 J. Dixon, Aberburch-yard, City, contractor. Improvements in the construction of floating saloon baths.

Dated January 28, 1868.

293 T. Hydes, ironmonger, and J. Bennett, engineer, Sheffield. Improved means or appliances for facilitating the transit and application of caloric, also for mixing caloric with air, water, and other fluids and gases, also for economizing the consumption of fuel, consuming smoke, generating steam, and increasing and distributing heat, and for refrigerating purposes.

Dated January 29, 1868.

312 G. Thornton, farmer, Chesterfield. Improvements in straw elevators to take straw from thrashing machines.

Dated January 30, 1868.

331 C. H. Roeckner, Whitchurch, Hants. Improvements in machinery for the manufacture of paper.

Dated February 4, 1868.

379 T. Scott, Fushie Bridge, Mid Lothian. Improvements in kilns or apparatus for drying grain, or other granular matters.

381 A. C. Sterry, Woodgate Cottage, Ewell, Surrey. Improvements in, and applicable to, locomotive engines and carriages on railways.

383 P. Graham, Oxford-street. Improvements in corks or stoppers for closing bottles and jars.

385 W. E. Newton, Chancery-lane. Improvements applicable to steam boilers for automatically sounding an alarm at the extremes of high and low water, also for automatically sounding an alarm when the steam in the boilers exceeds a given pressure. (A communication.)

Dated February 5, 1868.

387 T. W. Walker, Poole, Dorsetshire. Improvements in the manufacture of bricks, tiles, slabs, and other like articles, and in the materials and machinery or apparatus employed therein.

389 S. G. Taylor, Tyldesley, Lancashire, spinner and doubler. An improved mode of lubricating the spindles of machines for spinning and doubling.

391 F. Ardache, St. Vaast, Hainaut, Belgium, printer. Improvements in apparatus for winding flat cords, ropes, and bands.

393 H. Bunning, jun., Field House, New Cross. Improvements in apparatus for burning combustible liquids in furnaces.

395 W. E. Newton, Chancery-lane. Improvements in buttons, and in the means of securing them to garments or other articles of wear or use. (A communication.)

397 J. A. Jones, Middlesborough, engineer. Improvements in the production of iron and steel.

Dated February 6, 1868.

399 C. W. Guttridge, Landport, Hampshire, grocer. An improved apparatus for cutting soap.

401 A. E. Borgen, Corn Exchange Chambers, Seething-lane, City, merchant. The preparation of phosphor free matches, made either with or without paraffin, stearine, or wax, without the use of phosphor, and without requiring any prepared surface in order to obtain an instant light. (A communication.)

402 W. J. M. Rankine, of the University of Glasgow, Professor of Civil Engineering and Mechanics, and J. M. Gale, Glasgow, civil engineer. Improvements in condensing steam, and in apparatus therefor.

403 H. Brindle, Leyland, Lancashire. Certain improvements in shuttles to be employed in looms for weaving.

404 J. Honeyman, jun., Glasgow, architect. Improvements in arrangements and apparatus for trapping and ventilating in connection with drain or other pipes.

405 W. E. Newton, Chancery-lane. Improvements in steam gauges. (A communication.)

406 J. C. Cole, Smethwick, Staffordshire, engineer. Improvements in drill braces, applicable also to spanners and other like implements.

407 J. T. White, King Edward-street, City. Improvements in fire-lighters.

408 G. F. Bradbury and T. Chadwick, Oldham, sewing machine manufacturers. Improvements in, or applicable to, certain sewing machines. (A communication.)

409 B. M. Oakeshott, Sloane-square, Chelsea. An improved hot air simple or medicated vapour bath.

411 W. Tongue, Kennington, engineer. Improvements in machinery for straightening and preparing fibrous materials for combing or spinning.

412 P. E. Masey, Regent's Park. Improvements in machinery or apparatus for obtaining aerial locomotion, part of such improvements being applicable to rotary steam engines and boilers for other purposes.

413 H. W. Hart, Norfolk-terrace, Bayswater, engineer. Improvements in the manufacture of safety envelopes.

Dated February 7, 1868.

414 C. and C. H. Longbottom, Bradford, agents. Certain improvements in, or applicable to, machinery for spinning, twisting, and winding fibrous substances, and to looms for weaving.

415 J. O'Donnell, Woburn-mews West, and T. Arkill, River-street, King's Cross. Improvements in apparatus for raising and lowering venetian and other blinds.

416 S. Read, Edinburgh. Improvements in finishing paper and textile fabrics, and in the machinery or apparatus connected therewith.

417 J. and J. Cash, Coventry. Improved machinery for the manufacture of looped and textile fabrics, and in the fabrics produced thereon.

420 G. Tucker, Canonbury-road, St. Mary, Islington. Improvements in the manufacture of rain water pipes and certain other articles in cast iron.

421 W. Drake, Park Wharf, Nottingham, timber merchant. Improvements in machinery or apparatus employed in the cutting of wood, laths, and for other similar purposes.

422 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in locks. (A communication.)

Dated February 8, 1868.

423 J. B. Wilson, Haydock, Lancashire. Improvements in compressing, forging, and rolling steel and other metals, and in machinery for such purposes.

424 G. Harford, Newcastle-upon-Tyne, sail cloth manufacturer. Improvements in scaffolding and apparatus to be used for building and other similar purposes.

425 A. M'Knight, Birmingham, manufacturer. A new or improved powder or composition for cleaning and polishing articles made of steel, iron, copper, brass, or other metals.

426 T. Walker, Birmingham, engineer. Improvements in the construction of sewers and drain pipes or tubes.

427 P. Rothwell, Hampstead-road, gas engineer. An improved regulating valve for the delivery of specific quantities of gas, water, or other fluids.

429 J. Dixon, Nuneaton, Warwickshire. Improvements in the manufacture of braces.

433 J. Key and E. Hoskins, Birmingham, metallic bedstead manufacturers. Certain improvements in metallic bedsteads.

435 W. Brooke, Manchester, merchant, and R. Edmondson, Bank Top Mill, Blackburn, manufacturer. Improvements in heads for weaving.

437 J. E. Billups, Cardiff, contractor. Improvements in separating powders of sulphate of barytes of various degrees of fineness, thus obtaining an exceedingly fine powder, and in the separating apparatus adopted for the same.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the "London Gazette," February 25, 1868.

2846 C. Avery. Breech-loading fire-arms.

2868 J. Buckingham and J. S. Block cy. Regulating the feed of steam boilers.

THE

MECHANICS' MAGAZINE.

LONDON: FRIDAY, MARCH 6, 1868.

COMPARATIVE MERITS OF ZINC AND COPPER AS COATINGS FOR THE PROTECTION OF SHIPS' BOTTOMS.

A SHORT time ago we noticed that the iron plates which were coated with zinc on Mr. Daft's plan had been taken out of the water alongside Portsmouth dockyard, after an immersion of nearly three years, and that they were found to be in a satisfactory condition to those concerned, being covered with a thin deposit of mud only. That iron plates protected by a coating of zinc received no damage from the chemical action of sea water was proved some years ago by the experiments instituted by Dr. Calvert and Mr. Johnson, of the firm of Richard Johnson and Nephew, galvanizers, of Manchester, which experiments and their results were published in a small pamphlet at the time, and noticed by us in this Magazine. It was then shown that, practically, sea water had no chemical action on galvanized iron, and it was thence concluded that galvanized iron was the proper material of which ships should be built, at least to above the water line. No doubt, it was hoped by the experimenters that those who use iron ships would see their own advantage in the use of galvanized iron, and thus contribute to the advantage of the galvanizers. But they have not seen it yet: they are an obtuse set, these shipowners; still we think there is something to be said for them even, although Mr. Daft has again proved the same fact to them. The fact is that shipbuilders are bewildered with an embarrassment of expedients for the protection of ships' bottoms from fouling and corrosion. Copper, zinc, paints, cements, glass, soaps, and even kitchen stuff (!) have each in turn been recommended, and even patented, as the one thing needful to prevent the evils of fouling and corrosion.

Amongst all these expedients there is no question that copper or zinc are the most likely to succeed: yet which will—who shall say? Copper and zinc have each their advantages and their disadvantages, and, moreover, each possess advantages that the other does not, even supposing them to be successfully applied. There is more difficulty in the application than has yet been noticed by anyone. The advantages claimed for zinc are these,—that it is not attacked by sea water, that it is electro-positive to iron, that it is easily applied to the iron, and that it is inexpensive. The advantages claimed for copper are these,—that it is but slightly acted on by sea water, that it *is* slightly acted on by sea, thence producing a poison which destroys shellfish and sea weed. Copper being much less acted upon by sea water than iron is, it acts as a protector to the iron from corrosion; still, being slightly acted upon, thence producing a poison, it protects the ship from fouling. Zinc, not being acted upon by sea water, effectually protects the ship from corrosion, but then, from this very inaction, it must fail to protect the ship from fouling. An advantage is claimed for zinc over copper in that it is electro-positive to iron, while copper is electro-negative; consequently, it is said that if by any means the zinc were abraded no evil would happen to the iron: the zinc, being positive, would alone suffer and the iron be protected; whereas, if the copper were abraded, the iron only would suffer, the copper being negative to it. It is unquestionable that in case the copper were abraded the rapid destruction of the iron would result' but with regard to the alleged properties of zinc in sea water the results of abrasion are not quite so clear.

It is alleged that zinc is inactive in sea water, but that iron is active; which, then, is positive? We should say the iron, and we think all electro-metallurgists would say the same. How, then, would zinc protect iron in such a case? The iron must be destroyed and the zinc protected by the iron, which is a result not to be wished for, neither devoutly nor otherwise. If this be so, then zinc is open to the same objection as copper, in this, that in case of abrasion it will be the means of the rapid destruction of that which it was meant to protect. However, we must confess that we doubt the statement that zinc is less acted upon in sea water than copper is, and we will give one reason at least which we think is conclusive. A good many years ago the copper sheathing of wooden vessels did not last so long as the owners of the vessels desired (which is not surprising at any time); consequently, a remedy was asked for. Sir Humphrey Davey said to these shipowners, "I will tell you what to do; nail pieces of zinc on to your copper sheathing, and the copper will be protected, and the zinc only will be wasted away." Of course, it was immediately done, and the result was as the great chemist had said it would be; but there was another result along with it which was neither expected nor desired, namely, this, that though the copper was preserved it would not protect the ship from fouling; therefore the zinc was discontinued. There are two advantages which zinc has over copper, and these are, that it is more easily applied than copper, and is much cheaper; but then copper prevents fouling and zinc does not, though it will prevent corrosion.

On consideration, we think that the prevention of fouling is of at least as great importance as the prevention of corrosion. All we have said on this matter is on the supposition that the coatings are successfully applied. Taking the last two methods of applying the two metals to the iron, namely, Barnabe's for copper and Daft's for zinc, we see many difficulties to be overcome. The separate plates being coated—and what sane person would attempt to coat a whole vessel at once—these single plates must be riveted together. If the coating be copper it will hardly stand hammering down at the joints; besides, how are the rivet heads to be protected; in fact, whether the coating be copper or zinc the same difficulty will be found in building the plates into the bottoms of ships. We do not see any chance of successfully applying either copper or zinc directly to ships' plates. With respect to armour plates the case is different, for these are attached to the vessel with screw bolts, the heads, or the whole of which, can be covered with the coating metal. For armour plates we think copper has the advantage, as it prevents not only corrosion but fouling. To apply a protecting coating to the bottoms of ships successfully, we think it is clear that it must be as a sheathing, and between the sheathing and the iron there must be some insulating substance to offer some protection in case of abrasion. This being done effectively, as we think it can be, then we would say copper is the best material.

PRESSURE OF GAS IN CITIES AND TOWNS.

IN spite of all attempts to supersede its office and usurp its functions, coal gas has continued to maintain its supremacy, ever since the introduction of that useful and brilliant method of artificial illumination. From the time when the allied sovereigns paid a visit to London in 1814, and an ornamental structure in St. James's Park was lit up by 12,000 gas-lights in honour of the occasion, until now, all endeavours to substitute a material other than coal for the same purpose, have proved completely abortive. Strenuous efforts were made both by private individuals and incorporated companies in favour of oils, resins, fats, and numerous bituminous substances, all of which turned out utter failures when subjected to the trying ordeal of purchased shares and negative dividends. A few of the provincial towns, among which may be included Liverpool, encouraged the erection of works and premises for the manufacture of oil gas, but, unfortunately, the speculation turned out so gross a miscalculation, that apparatus for making gas from coal, was ultimately established upon the very site selected for its anticipated rival and supplantor. Theoretically, the superiority of oil gas is well known. It is free from most of the impurities common to coal gas, and has a far greater illuminating power. The facts of its ill success as a counter scheme to its rival is worth noting, as a proof that however accurate theory may be, it is worth little or nothing if it cannot combine with or adapt itself to the requirements of practice.

The question of the regulation of the pressure of gas has always been one of considerable importance in its distribution and consumption. It is not merely a matter of uniform and constant flow from the gas works, as might be at first imagined; the problem to be solved is much more difficult and complicated. What is required is that the flow should take place under conditions, which would allow the consumer to receive it under a constant pressure—a pressure which should be regulated in a manner, so as to be perfectly independent of the variations taking place in the gasholders, and totally uninfluenced by the different obstacles and impediments inevitably contingent upon an extended course of service pipes, and the disadvantages of lighting a large district. Manifestly, if we suppose the gas to have quitted the gasholder, and entered the principal main pipe with a constant pressure, any want of uniformity subsequently apparent in its flow, must be due to the medium through which it passes, and by which it is conducted to the burners. A uniformity of pressure into the chief main from the holder can always be insured by means of a "governor," which regulates the escape of gas into the pipe, quite independently of any inequality of action in the gasholder, or any other cause which might be at work to retard or accelerate its flow. Through a pipe of a certain size a certain quantity of gas can always be passed, but, according to the ratio existing between the volume of gas passing through in a unit of time, and the sectional area of the pipe, so will the flow at the end of the pipe take place with or without a loss of the pressure it possessed on entering it; in other words, there will be a difference between the final and the initial pressure. There is, in fact, a limit to the velocity, which determines whether the pipe should be regarded as a reservoir, or as a channel of efflux. From experiments recently made in Paris, it appears that when the velocity of the gas exceeds 8½ft. per second, the pipe becomes a channel, and no longer acts as a sort of reservoir. It is a very simple matter for anyone to convince himself of the variation in pressure that occurs with respect to the supply of gas in London. All that he has to do is to regulate the cock, so that the stream shall be steady, and then observe it for five or six hours, or longer, and it will be found that at times during the night the flame will increase so much as to actually sing, and at others it will sink so low as scarcely to afford half the quantity of light it would at another time. This arises, unquestionably, from the variation in the actual number of lights burning at the same period—that is, the pressure depends upon the number of burners in connection with the whole system. By this it is not intended to convey the meaning that

Digitized by Google

the initial pressure is understood, but simply that the pressure or its equivalent, the velocity, with which the gas reaches the consumer is materially influenced by the number of outlets in the vicinity. There is clearly a proper velocity, or, to speak more correctly, a minimum, adapted for burning the gas. If the velocity of flow be greater than the rate of combustion, there is a loss at once accruing to the public.

AMERICAN SMALL ARMS.

THE position of the heavy ordnance question in America, as revealed by the report of the Chief of Ordnance, General Dyer, recently occupied our attention. We now turn to the same source for information relative to small arms and ammunition. The chief features of the past year in this respect appear to have been the conversion of a number of Springfield rifled muskets into breech-loaders, and the introduction of central-fire cartridges into the service. Over 23,000 rifles had been converted up to the date of the report—October 19, 1867—but since then a great many more have been turned out of hand, so that at the present time the converted arms number about 50,000. These have been issued to the troops as fast as completed, and now nearly all the infantry serving in the departments of the Missouri and the Platte are armed with them. Monthly reports have been received by the War Department from the commanders of companies armed with this weapon, and which have been highly satisfactory and favourable to the arm, and furnish abundant evidence of its excellence and fitness for the military service. The almost unanimous opinion expressed by the officers is that the musket is simple, strong, not liable to get out of order, and extremely accurate in firing. Some officers have suggested slight modifications for the improvement of the arm, but the defects mentioned by them are said to exist in the unconverted arm, and to be in no way connected with the peculiar method of conversion. A few officers have recommended a further reduction of the calibre, while not one has expressed the opinion that it is too small. In a campaign against the Indians during last summer these arms are said to have done excellent service, very few having been rendered unserviceable. More have been reported as rendered unserviceable through carelessness than from all other causes. The report does not give any idea of the principle upon which the rifles are converted, which, to our mind, is a pity, as we should like to know which of the many American notions has been adopted. From the introduction of central-fire cartridges we of course infer the general principle of the new weapon, but we should like to have had a few details. Whatever the principle may be, we think it must be very far from perfect if it allows carelessness to render it unserviceable. This, too, indicates a defect in the military system which permits of such carelessness. The General, however, is very confident of this arm, firmly believing that no musket has been converted into a breech-loader in his country, nor in Europe, which is superior for military purposes to that which has been produced at Springfield Armoury, and that none equal to it in serviceable qualities can be produced at less cost. He, however, intimates that the arm is susceptible of some slight improvements, which, in fact, are to be introduced into future weapons. This is significant: trifles are sometimes of the first importance.

It is amusing—and might be instructive, if we had not had lessons enough here—to note the difficulties which the War Department has had to contend against in producing a good breech-loading musket. They arose from the impossibility of making any improvement which was not immediately claimed under some one of the many patents which have been granted for improvements in fire-arms, and from the extreme eagerness and strong efforts of some inventors and other parties interested in patents to have their improvements used by the Government. Many persons claimed to hold patents for improvements which were used in the conversion of the Springfield muskets; in some instances, several parties claimed to hold patents for the same thing, and it is believed that every improvement was claimed by more than one inventor. Rather warm work this for the department; so the officials declined to acknowledge the validity of any patents for improvements used in the conversion of the musket, knowing that it was not competent for them to decide the question, and believing that the proper course for patentees to take was to establish satisfactorily the validity of their claims, and then apply to Congress for compensation for the use of the patents. Congress will have enough to do if these inventors are only half as clamorous and persistent as some we have had to deal with in England. It does not speak well either for the Patent Office that a number of patents have been granted for the same thing. But these gentlemen will have to prove their claims before Congress will settle their little accounts, and this preliminary process will doubtless greatly thin their ranks.

We have already stated that the central-fire cartridge has been adopted, and the report states that they are "the first of the kind that have been introduced into the military service of any country, or manufactured anywhere in considerable quantities." Now, in this we differ from the gallant General, inasmuch as in our own country the central-fire cartridge was introduced into the service a year and a-half ago at least, and more than "considerable quantities" of them have been turned out, and a pretty noise they have made one way and the other. Going into figures, the General reports that about fifty thousand *can be* produced daily at Frankfort Arsenal, although he does not say how many *are*. The number, however, must be considerable, as upwards of seven millions have been manufactured, and 367,943 have been fired by troops, and in proving muskets and ammunition, only 1,317 of which have failed to explode—about one-third of one per cent. It is believed that no other cartridges have ever given such good results. Upon the whole, the total grand result of the report must strike every one as highly satisfactory—the best ordnance, the best small arms, and the best cartridges. The judgment of the reporter is, of course, based upon protracted trials, but with regard to the small arm we should like to have had some particulars of the trials. We are not indisposed to take for granted the statements of an official report, but as, in the case of the heavy guns, General Dyer entered somewhat into detail, we are a little disappointed that he did not do so with respect to the small arms. It would have enabled others to judge for themselves as to the high order of efficiency of the weapon had its principles of construction and the details of the experiments been vouchsafed.

THE EXPERIMENTAL FORTIFICATIONS AT SHOEBURYNESS.

THE question of our national defences has, like most questions, two sides. On the one hand, it is contended that forts should be so constructed as to be perfectly impenetrable to shot, even at the closest ranges. On the other, it is urged—chiefly by military men—that only such power of resistance is required as will meet the probable hazards of war. The one party would have our soldiers stowed carefully away behind an impregnable shelter, constructed at immense cost, their pluck and prowess being to a certain extent ignored, whilst the other gives the soldier credit for the possession of those qualities to which, in the main, victory in battle is due, and would see them properly sheltered within less expensive structures. We are not now going to discuss this question, but will merely observe in passing that considering what we are doing afloat, the second proposition appears by far the more reasonable for application ashore. The question of the best method of carrying out the principle of coast defences will, however, shortly be put to a practical test at Shoeburyness, where some experimental structures have been erected. It is our present purpose, then, to give our readers some particulars of these representative forts; when the experiments have been carried out we shall report the results.

The first point to which we would invite attention has a direct bearing upon the question we have already referred to, inasmuch as it involves the testing of various methods of protecting guns and men. With this view, a casemate has been erected which is covered with several kinds of armour and backing. The piers which carry that part of the arch immediately over the gun are 12ft. wide and 8ft. deep, and are covered with ¾-inch iron plates connected by angle irons with the protecting plates. The armour consists, in the first place, of a course of 2-inch plates which are laid over the entire face of the casemate, except, of course, the port. Where this plating is unsupported by the piers—as, for instance, in the space under the arch, which is allowed for traversing the gun—it is backed by a row of vertical caissons. These caissons are simply 15-inch cylinders, made of ¾-inch iron, and filled in with concrete; they are riveted to angle irons and cross bars of ¾-inch iron. The port is 3ft. wide and 3ft. 6in. high, outer dimensions, and it allows the gun a lateral range of 70deg. On each side of the port, and immediately in the rear of the armour-plate, is a solid forging of iron 9ft. long, 9in. wide, and 13in. deep, placed vertically, and which thus strengthens this, the weak point of the structure. These forgings are strengthened by horizontal distance pieces of iron 6in. wide and 7in. deep halved into them at the levels of the port sills. The tops of the forgings are bolted to a horizontal iron bar, having a sectional area of over 6in., and being bedded in the concrete backing, whilst at the bottom they are secured to a horizontal plate of 3-inch iron. To guard the gunners within from accident from splinters, the arches are lined with ¾-inch iron plates, and iron screens of the same thickness are placed inside. The piers and arch are built of concrete and brick in cement, the other parts of the casemate being of brick in cement. The brickwork of the arch is 18in. thick, and that portion of it which covers the space between the caissons and the piers is carried by wrought-iron girders. Above the brickwork is a course of concrete, which is 15in. deep at the crown of the arch. Bolt tubes are built into the masonry, and pass through the backing, so that the armour-plate bolts can be taken out, and the plates removed without disturbing the rest of the structure. This method of building in the tubes affords great facilities in constructing the works and plating them at the finish.

We now come to the armour-plating, of which there are in the present instance no less than six varieties, four of which contain a quantity of iron equal in each case to an 8-inch plate. The fifth has an amount equal to 8½in., but the sixth only equals 4½in., the space between it and the 2-inch plate being filled in with concrete. The first target of the six, counting from the left hand of the beholder, is a vertical strip of plating 4ft. 3in. wide and 8in. thick. The second is a strip of armour of the same width, but only 4½in. thick, connected with the 2-inch backing by hollow iron stringers placed vertically. These stringers are 7in. deep, and of a section giving an area equal to a 3½-inch plate. At this point in the casement is the port, and

Digitized by Google

here is a course of 6-inch plating which extends across, above, and below the port, as far as its right edge. This plating is also carried on vertical stringers, but of a different pattern from the last, being Mr. Hughes' patent, with the shape of which our readers are doubtless familiar. The sectional form is somewhat that of the Great Western, or bridge rail, the area being in the present case about equal to a thickness of 8in. of iron. This armour is supported partly by the left pier and partly by the cylindrical caissons. On the right of the port is laid 4-inch armour-plating for a width of 3ft. 4in., carried on vertical stringers, similar to those used in No. 2 target, but somewhat heavier, to compensate for the loss of half an inch in the diminished thickness of the front plate. From the edge of this plate to the end of the casemate a 4½-inch plate is laid, partly on stringers, similar to the last, and partly on concrete, forming thus the fifth and sixth targets. The frontage presented to the firing gives a total area of about 360 square feet, the length being 30ft., and the height 12ft. We should add that this casemate is purely experimental, and does not represent anything previously constructed.

Turning to the representative structures, we first notice the Plymouth Breakwater Fort, which is in course of construction, the ironwork having been contracted for. As a simple shield is clearly an incorrect representation of a complete fort, some additions have been made in this target in order to render it similar, as regards strength, to the fort it purports to represent. Externally the front is an iron-plated target, 21ft. 9in. long, and about 13ft. 6in. high. The face slopes inwards 1ft. in the first 11ft. of its height, and above that it assumes a retiring angle of 45deg., the iron plating being reduced to a thickness of 3in. The outer armour consists of three 5in. plates running horizontally, out of the lower two of which the port, 2½ft. wide and 3ft. high, is cut. In rear of this armour is a layer of iron planks about 16in. wide, and 5in. thick, placed vertically. Behind these is a layer of similar planks above, and plates below, placed horizontally, and so as to break joint with the other planks and armour-plates. The total thickness of iron is, therefore 15in. The armour is supported by five iron girders, which are run up the back of the iron planks and armour to which they are bolted by through bolts. Each girder consists of two iron planks 1ft. wide and 5in. thick, placed 6in. apart, and connected at the top and bottom by cross bolts, while the bolts which pass through the armour and between the girder planks are secured by nuts to cross pieces of iron 1½in. thick, which connect the girder planks, and bind the whole ironwork firmly together. As, however, the fort is built of iron on a granite foundation, it is necessary that the tough plates be securely imbedded in the solid stone. To this end an iron plate, 2ft. 7in. wide, and 2½in. thick, is laid in a recess cut in the granite floor, and extends along the whole front. It abuts against the inside of the lowest armour-plate, and carries the planks and back lower plates, their edges being laid upon it. Holes cut through it, and about 6in. deep into the granite, receive the feet of the girders, which are thus rooted in the solid foundation, and serve to hold firm the foot of the armour. The plating and its vertical girders abut at the top against an iron plate connecting the ends of longitudinal girders, which support the arches of the casemate roof, and are in their turn held up by a box girder, supported at its extremities upon piers of brick in cement 4ft. thick, cased with ¾-inch iron plates. Between these piers and the rear of the armour-plate girders, a clear space is left in order to prevent any damage the front may receive from affecting the stability of the piers and roof, and also that the bolts passing through the armour-plating and girders may be reached for removal.

The essential points in which this experimental front differs from the fort itself may now be referred to. In the first place, in order to compensate for the want of continuity of thrust obtained in the fort, tie-rods are built into the arches of the experimental front. In the true fort the front is oval, whilst in the experimental one the face has been made flat, in order to save expense. This, again, gives a weak point, to meet which the shape of the pier has been slightly altered. An old piece of masonry having been utilized, there is not room for an entire pier; its dimensions, therefore, have been reduced. Again, the spacing of the roof girders is not quite the same, because the target, representing only a part of the real fort, could not have its girders projecting in the air. The ends of the plates lack the continuity of support obtained in the fort. This is to some extent met by increasing the size of the end bolts, but in any case the ends must be weaker than the same points in the fort. One or two alterations have been made in the target, which, however, are to be introduced in the fort itself. For instance, muzzle-pivoting carriages are to be used in future, so that the size of the fort is greatly reduced. The substitution of an iron plate in the third thickness instead of iron planks is also new, but is likewise ordered for the fort. Spare test-plates will supply the iron wanted for the purpose. The experimental work has, however, one advantage in this respect, that the hind plate will be about 21ft. 9in., while in the real fort the length is about 14ft. Other forms of armour-plating might be substituted for the one at present proposed, without altering the piers or the iron roof supports, but the War Office estimates show that this would involve an extra expense. The ironwork for the experimental front costs about £2,500 per gun, whilst the plates and compound backing for the armoured casements cost about £2,800 per gun. John Brown and Co. propose solid plates 14in. or 15in. thick, held between vertical iron beams grooved to receive the edges of the plates. This system, according to the War Office estimate, is calculated to involve an outlay of about £3,500 per gun for ironwork alone. This is, of course, a very large advance on the other systems, although the advantage gained in having a solid plate would be very great. But we are inclined to think the estimate is based on the production of only a few of these large plates, inasmuch as we have been informed by the above-named eminent firm that when these extra thick plates are required in anything like quantity, the cost will be but little higher than that of the ordinary plates. A system of 18-inch cast-iron backing and an 8-inch plate with an inner skin of 1-inch iron could be produced for about £2,000 per gun.

The last structure we have to notice is the Millwall shield, which was originally made by the Millwall Company, for a trial of Mr. Hughes' stringers by the War Office. This shield has a front of 12ft. by 8ft., and is composed of armour-plates 6in. thick on the upper half, and 9in. thick on the lower half. The backing consists of Mr. Hughes' wrought-iron stringers placed horizontally, their sectional area being about equal to a 2-inch plate. Behind the stringers, and riveted to their bases, are two thicknesses of ¾-inch plates, which rest against another series of stringers placed vertically, and having a depth of about 7in. We understand the cost of this shield to be £1,200, or £200 more than that of the Gibraltar shield. The hollow tubes for the bolts are introduced in the Millwall shield. To test the increased resistance to be obtained by adding plating to the outside of existing structures, three 1-inch plates have been bolted to the outside of half that portion of the shield protected by the 6-inch plate. The whole shield is further strengthened and supported by iron struts at either end. Besides the foregoing, there will be trials of some of Sir John Brown's 15-inch and other heavy armour plates, the results of which will add materially to the value of the experiments. According to the present arrangement, which, however, may be altered before the experiments are commenced, these structures are to be tested by firing from heavy guns. The 12-ton, the 18-ton, and possibly the 23-ton rifled guns, and the 19½-ton American 15-inch smooth-bore gun, are to be brought to bear on them. We shall look forward with interest to these trials, as their results cannot fail to prove highly instructive. We are also hoping for particulars of the gunnery experiments at Fortress Monroe, in America, which were talked about some time since, and which would be highly useful for comparison with our own results.

NOTICES OF BOOKS.

NO public questions, affecting vitally the material condition and comfort of the people, and the welfare of the community, are of greater importance, or better entitled to attention, than the questions of water supply for our cities and towns; and, again, the kindred subjects of the most effective mode of removing, and the most profitable way of disposing of the waste matter in sewage which proceeds from our clustered population. These important subjects are ably dealt with in the volume before us.* Mr. Haskoll dashes into his great subject of water supply rather abruptly, and in such style as to convey the impression, which his text serves to confirm, that he is perfectly familiar with his subject. In the first chapter, an immense amount of interesting information *apropos* of catchment basins is given relative to the upper basins of the Severn; to the rainfall on the gathering grounds of the Manchester Waterworks in Longendale Valley; to the fall in the Cumberland and Westmorland lake districts; and in the gathering grounds of Loch Katrine, and the district from which the city of Glasgow is supplied with water. The subject of rainfall is exhaustively discussed by the author, who has been at great pains to collect a large mass of valuable information from almost all parts of the country. The geology of the subject in relation to water supply from under ground is also fully treated; and, in connection with this branch of the subject, all is said that needs to be advanced in relation to well-boring. Many very curious facts are given by the author relative to the bodies and supplies of fresh water which are to be met with in various situations, and subject to various influences and circumstances, in different parts of the country. The distinctive chemical qualities and ingredients of such water supplies is also fully narrated, and the mass of facts and observations brought together upon the subject, as a whole, is so complete as to entitle Mr. Haskoll's book to rank as an indisputable authority upon many points of this important subject, and to be accepted as a trustworthy guide by all who are concerned in this branch of engineering practice.

The author discusses with equal thoroughness the cognate subjects of sewage and sewage utilization; and, as in the case of water supply, he gives full particulars concerning actual systems, as well as theories, and discusses the most important achievements and projects for dealing with the valuable products known as sewage, which have been hitherto almost entirely wasted. The undeniable merits of Mr. Haskoll's work are its comprehensiveness and lucidity, the large mass and masterly arrangement of the information it contains, and, not least, the author's thorough independence in his treatment of the vexed questions with which he has undertaken to deal.

It is at all times delicate, and it is often

* "The Practice of Engineering Fieldwork, Waterworks, Sewers, Sewage, and Irrigation." By W. DAVIS HASKOLL, C.E. London: Atchley and Company.

Digitized by Google

difficult, to judge correctly of motives, but it may not be doubted, as to the production of many books, that, like Peter Pindar's razors, they are "made to sell." Some authors reel off their text as the conjuror draws ribbon from his mouth, and others make books by the help mainly of scissors and paste. One class of author is content if his book sells, and is perfectly indifferent as to whether anyone is the wiser or the better for its publication; and bookmakers of another class are pleased enough if they see their name in print, for "a book's a book although there's nothing in't." But there is another and a higher class of writers, with whom profit, or the exhibition of their names upon title pages, are very subordinate considerations, who collect and elaborate with great labour and toil a large amount of valuable information, which they digest and reproduce with a view to far higher practical purposes than their now fame or aggrandisement. Of this class of work is the book before us.* The subject undertaken by the gallant and accomplished author is intrinsically dry and difficult of treatment, but, as regards the one quality, he contrives to invest the subject with much information that is fitted to interest any reader of ordinary intelligence, and, as regards the difficulty of the subject, he lays down his premises firmly and clearly, and draws from them conclusions that only a sophist will attempt to controvert. Colonel Smith was formerly Master of the Calcutta Mint, and in that capacity acquired such an amount of knowledge on this intricate subject as has given him a complete mastery over it. He accepts the conclusion of the Indian Government Commissioners on Currency that the demand for a gold currency is almost unanimous throughout India, but he dissents from their recommendation to introduce a ten-rupee gold coin as a legal tender, and recommends instead the introduction of the sovereign as the basis of the Indian currency. As touching the desirability of the introduction of gold into India, he adverts to the absurdity of ships traversing half the globe freighted with gold in one direction, and with silver in another, for the adjustment of balances of trade capable of settlement without either voyage, and with a saving of expense of a quarter of a million sterling annually. The writer gives incidentally a great amount of valuable and interesting information touching seignorage, the value, and fluctuations in value, of the precious metals, and upon other subjects. He shows conclusively that his recommendation might be adopted satisfactorily by an easy adaptation to it of the rules and practices of the Mints, and urges that the adoption of the recommendation of the Commissioners, as regards their proposed mode of conversion, would inevitably be attended with disastrous consequences. It is to be hoped that Colonel Smith's able statement may secure, as it well deserves, the attentive consideration of those whom it may concern, and primarily of the Secretary of State for India.

Much matter crops up from day to day to remind and impress us that the railway interest is of vast magnitude and importance. The annual returns by the Board of Trade concerning railways, to which we recently adverted, communicate a great mass of interesting particulars touching the number of miles open, capital, passengers, live stock, goods and minerals carried, traffic receipts, rolling stock, &c.; but this compendium is altogether barren in one important particular —the number and classification of the employés who conduct, or are concerned in the conducting of this enormous traffic. This information is supplied in an admirable little work,† by Mr. W. F. Mills, of the Railway Clearing House, the indefatigable secretary of the Railway Servants' Provident Society. The special design of Mr. Mills' work is to investigate and record the numbers, classification, wages, and special hazards of railway employés, and to give an account of the various provident societies connected with the service. In 1860, a Parliamentary paper was published, giving the numbers of the respective classes of railway officers and servants then employed in the United Kingdom, but no similar return has been published since that date. Taking that return as his datum, and including the 4,000 miles opened since then, Mr. Mills arrives at the conclusion that there are now employed in connection with the railways of the United Kingdom 19,962 officers and 200,008 servants, or a grand total of 219,970. Of the first class there are 438 secretaries and managers, 3,933 station masters, and 13,297 clerks. In the second class are 5,171 engine drivers, and rather larger numbers of firemen and guards respectively, with 40,167 artificers, 25,381 porters, 12,901 platelayers, and 81,284 labourers. Mr. Mills's principal object in the interesting work he has produced appears to be to promote the interests of the provident societies connected with railways, of which he gives a full account. His labour in his book appears to have been undertaken and gone through *con amore*, and will, we hope, serve well the purpose for which it was intended. It is well worthy of the attention of the general reader, and certainly demands the attention of all who are personally connected with "the railway service."

One of the first attempts to produce a succinct or condensed account of the "Exposition Universelle" has been forwarded to us from Paris,* in a *brochure* of some 220 pages. It does not pretend to be a record of everything that might be of interest to the scientific and professional man, but merely treats of the more important and salient features in connection therewith. We are somewhat at a loss to conjecture why so large a space should have been devoted to "Céramique-Glaces-Verrerie," and so comparatively small a number of pages allotted to a subject so important as that of "Matérial des Chemins de Fer." A chapter is given to the well-known establishment of "Creusot," a full description of which appeared in last year's volume of our contemporary "The Engineer;" and special notice is made of "The Dockyards of the Mediterranean." A history of these establishments will be found in our present columns, including an account of some of the most remarkable productions of their workshops. The subject of artillery is briefly treated of in a dozen pages, and the author considers the display of English ordnance to be particularly interesting, although Blakeley and some other manufacturers were not represented.

The latter half of the volume is composed of gratuitous information furnished by engineers, manufacturing firms, and others specially concerned in the various arts of construction and branches of industrial enterprise. One would suppose, at first sight, that but very little difficulty would be experienced in enlarging a volume to almost any extent by these means. The reverse the author states to have been the fact. So far back as 1865 the publishers intimated to all intending exhibitors that they would be glad to insert gratuitously any information, descriptions, and cuts, that would be useful and acceptable to the public, and anticipated a correspondingly liberal return for their offer. They confess to be very much disappointed, much of the information forwarded being of a character so limited that it was little better than useless for publication; and in many instances cuts and diagrams were sent without any accompanying description, and consequently had to be totally rejected. Such of the communications as could be rendered presentable have been collected, and constitute the "Documents Communiques" in the "Etudes." We think a considerable improvement would have resulted by arranging these short articles, notices, and paragraphs in alphabetical order, a plan that would greatly facilitate reference, and enable one to see at a glance whether any particular article was described in the volume.

ELECTRICITY AND TELEGRAPHY.

THE submarine cable from Dunwich to Zandvoort, on the coast of Holland, which we announced some time ago as broken, has lately been repaired. The time occupied in the necessary operations has been longer than usual, on account of the bad state of the weather, the unusual quantity of high winds compelling the repairing ship to remain in harbour.

We believe a Telegraphic Convention will be held this year at Vienna, to revise the last International Convention at Paris. We trust our Government will send over a representative on this occasion, and subscribe like the other European Governments have done to the Convention; from correspondence which has lately taken place we have every reason to hope they will do so. The position our Government stands in as owners of the Persian Gulf and Indian lines, and in view of the probable transfer of the English systems, renders it incumbent upon them to take part in the conference.

The submarine cable which connected the south of Sicily with the African coast has been for some time interrupted. The breakage is supposed to be about half way in deep water, at a distance of about forty-five miles from Marsala. The French steamer, "Dix Decembre," has been obliged to put back to Toulon, without—although many attempts have been made—being successful in repairing the cable; the two ends being broken in very deep water render grappling difficult. This vessel was fitted up by Mr. Siemens for repairing operations with the necessary machinery, but so arranged that the operations were carried out at the stem of the vessel instead of at the bows. Although this plan may be useful for suddenly reversing in paying-out operations, when a fault has occurred, and it is necessary to recover some of the cable, yet when the work required to be done is purely grappling and repairing, we certainly have the notion of an "old sailor that the bows of a ship are the proper place" for such operations. The "Dix Decembre" will take in more cable, in order to complete the repairs at an early date.

We anticipate shortly an announcement that the rates for messages in Italy will be greatly reduced.

Portugal is following in the steps of France with regard to her recent innovation for telegrams to be forwarded to vessels at sea. We learn, by a Royal decree, that a system of semaphores is to be established on the Portuguese coasts in connection with the land telegraph, so that on payment of certain rates, messages can, as in France, be sent to vessels of all nations.

We have at various times noticed electric thermometers, but lately a thermometer has come under our observation that we are not aware of having appeared in our columns: the invention is for making electricity, in connection with a thermometer, regulate the temperature of a room. The apparatus consists of an ordinary mercurial thermometer, at the bottom of which, in connection with the mercury, is inserted a platinum wire. Another wire, capable of being elevated or depressed, is placed at the other end of the thermometer. These two wires are in connection with the two poles of a battery, and forming part of the circuit is an electro-magnet, whose armature controls the opening or closing of a valve for the admission of hot air.

When it is required to preserve a room at a fixed temperature of, say, 60deg., the point of the upper platinum wire is brought to the required number on the thermometer; the circuit being incomplete, the valve is open, hot air is admitted until the

Digitized by Google

mercury registers 60deg. When the circuit becomes closed the electro-magnet at once comes into action, and the valve is shut, cutting off the supply of hot air. When the temperature becomes reduced the valve is again opened; so, it will be seen, that a nearly even temperature can be maintained. This apparatus has already been introduced into practice, and so arranged in hothouses that the temperature has scarcely varied a degree.

Some experiments by Messrs. Janin and Roger on the light obtained from a magneto-electric machine confirm what has been already remarked, that the light from these machines is more applicable to lighthouse purposes than that obtained from a battery, on account of the light from the incandescent carbons being less blue and less rich with chemical rays. The object of these experiments was to observe the effect upon the carbons of the alternate direction of the induced currents of a magneto-machine. Throughout the experiments the light from the lamp with carbon points was continuous, but with the series of currents in the one direction the light had an increased brilliancy as well as the arc, whilst with the currents in the opposite direction, the arc was invisible and the carbons less brillant.

PHOTOGRAPHY.

PHOTOGRAPHIC GLASS—CHANGES IN GLASS—IRON IN GLASS—MANGANESE IN GLASS—GLASS FOR TRANSPARENCIES AND LUNAR PHOTOGRAPHS—CEMENTING GLASSES.

ALTHOUGH glass is popularly supposed to be one of the most unchangeable substances that man can make, the changes that take place in it very shortly after manufacture are of the greatest annoyance to photographers. The rays of the sun which act upon photographic films are, some of them, invisible to the eye, because they belong to the extra-violet part of the spectrum, and to most of these rays all kinds of glass are opaque. Hence a longer exposure of the plate in the camera is always necessary when a picture is taken in a glass house than when it is taken in the open air, because the period of vibration of the molecules of glass is such that some of the extra violet rays of the spectrum are absorbed and completely cut off from the sitter. Yet the photographer cannot day by day take all his pictures in the open air because of the changes of weather or temperature, the disturbance of dresses and drapery caused by wind, and because of other palpable impediments. So, at the outset, he is obliged to work beneath a medium which cuts off part of the photographic rays.

Glass not only cuts off most of the short invisible rays, but some of the visible part of the spectrum also, as may be seen by the greenish or yellow tinge of nearly all descriptions of glass. For this reason there has been a demand on the part of a few intelligent photographers for a very white and transparent glass for their operating rooms, that known in the market as "crystal sheet" being the description thus selected. Sad experience has, however, proved that the advantage gained at first by the use of white glass is lost in the long run, for, after exposure to daylight and sunlight for a very few weeks, this glass changes colour, most frequently acquiring a yellow tint, thereby becoming the very worst glass for photographic purposes. A glass of greenish tint, like those commonly on sale, is very objectionable in photography. A few of the white glasses acquire a slightly purple instead of a yellow tint by exposure to light, and if these samples could be known beforehand, they would be the best for photography, but nothing but experiment can test the fact. In the midst of all these difficulties the conclusion seems to be general that under present circumstances common crown is about the best glass for photographic houses, and that the sample chosen should be thin, have a blue rather than a green tint, but be as white as possible. A decidedly green glass should be rejected.

Mr. Gaffield, an American, has tried experiments with all kinds of common glass, his results showing that if a piece of glass be cut in two, and one-half be exposed for a few weeks to the sun, while the other half is kept in darkness, the former in the majority of cases will be found to have changed colour. His experiments were considered at the last meeting of the Photographic Society of London, and no better suggestion could be made than that common crown must be employed for the present. Mr. J. A. Forrest, a glass manufacturer of Liverpool, says that the clearness and transparency of glass depends much upon the kind of stove used in the melting, but the principal cause of deleterious change of colour of glass in daylight is the presence of an oxide of iron. This oxide of iron finds its way into the crucible, as a constituent of the sand employed in glass-making, and sand free from iron cannot be found either in this country or on the Continent. Some districts yield sand more free from iron than others, and as far as Mr. Forrest knows, the sand from Leighton Buzzard is the best to be had in Europe, next that of Fontainebleau, but the best of all is from the Cape of Good Hope. Iron causes the glass to have a greenish tint at first, changing to yellow by exposure to light. Therefore, the real question at issue is, whether it will pay glass manufacturers to get rid of this iron in the sand by chemical means, and to produce a better glass by lengthening the time of melting. If photographers were known to be willing to pay a higher price and to take large quantities of such a glass, the supply would soon meet the demand. It would be necessary that the photographic world should have convincing evidence from the manufacturer that his glass is durable and unchangeable, and not ordinary glass, sold as a superior article.

The presence of manganese in some samples of common glass causes rapid tinting of the glass on exposure to daylight, but as the colour thus produced is usually purple it is not so very objectionable.

Optical glass is often anything but durable. Some samples of it are troubled with a disease known to opticians by the expressive but not very nice name of "sweating." Others sometimes become covered with a white crust after long exposure to air, because of the large quantity of lead entering into their composition.

Of all photographic silver prints those taken on collodion, and afterwards cemented with Canadian balsam between two pieces of glass, are believed, for reasons recently set forth in this Magazine, to be the most imperishable. The amber tree of prehistoric times once dropped its liquid gum along the shores of the Baltic, and often did it fall "pat" upon an unlucky insect, preserving it to our day in its crystal case. Amber is a turpentine resin, so also is Canada balsam, and if the latter will only preserve the collodion picture as long as the former has preserved earwigs and blue-bottle flies, photographic transparencies are very imperishable. It has been said that a film of Canada balsam between two plates of glass rapidly becomes very brittle, also that arborescent cracks sometimes creep into the film of balsam which cements telescopic object glasses. Very little, however, is known as to the durability of films of Canada balsam between plates of glass, and information on the point is not easy to obtain. Nevertheless, most cemented lenses appear to be permanent enough, and to show no symptoms of coming apart after the lapse of years. Marine glue of pure quality has been suggested as a suitable cement for transparencies.

Supposing Canada balsam so placed to be, as a rule, practically imperishable, the question arises what is the durability of the glass enclosing the picture. Most kinds of glass, when finely powdered, are largely soluble in water, though not so when unbroken; hence it is supposed, with reason, that the inside of a sheet of glass is more pasty and soluble than the external surfaces. In the early days of photography it was found that "patent plate," a glass which has its natural surface ground and polished away, yielded more readily than common glasses to the action of hydrofluoric acid. Mr. Warren De La Rue once used what is called in the market "extra-white patent plate," in taking his photographic negatives of the moon; but after lengthened experience he rejected it because he found that the glass was so hygroscopic that it destroyed his negatives if they were left lying about in the observatory a considerable time before cementation to a second piece of glass. He now uses "polished flatted crown," selecting the pieces with great care. For all these reasons it seems that polished flatted crown is as durable a glass as can be used for cemented transparencies, and that crown glass is durable is proved by the fact that beads of it, several thousands of years old, have been found in Upper Egypt, in some of the tombs of the Kings. M. Stas, the celebrated chemist, is now giving attention to the questions affecting the durability of glass, and some of his experiments were recently recorded in the "Chemical News." Perhaps, after a time, now that so much attention has been drawn to the subject, a permanent, and in every respect satisfactory, photographic glass will find its way into the market. For all purposes, whether for glazing, for negatives, or for transparencies, it is desirable that a thin rather than a thick glass should be introduced.

NOTES ON RECENT SCIENTIFIC DISCOVERIES AND THEIR PRACTICAL APPLICATIONS.

NEW ALLOYS OF TIN AND LEAD—PROCESS FOR STAINING WOOD—PRESERVATION OF BUILDING MATERIALS—A MODIFICATION OF SORET'S CEMENT—MALLETT'S PROCESS FOR OBTAINING OXYGEN AND CHLORINE.

TWO new alloys of tin and lead are described by M. Plho. While containing less tin than is used in common pewter, they are said to possess most of the advantages of that useful alloy. They are not acted upon by vinegar, sour wine, or salt water. The first is made by melting 1 part of tin with 2·4 parts of lead. The lead is first melted and skimmed, then the tin is added, and the mixture is stirred continually with a wooden stick until it begins to cool, to prevent the lead from settling to the bottom. This mixture has the density of 9·64, and its melting point is 320deg. Fahr. It may be rolled cold, and the plates do not crackle when bent. It takes a very good polish, and tarnishes but little on exposure. It will mark paper like lead, and is so soft that it may be scratched with the nail, but it will not foul a saw or file.

The second alloy is made by melting together in the same way 1 part of tin with 1·25 parts of lead. This alloy is less elastic and harder than the foregoing. It is rather brittle, less malleable than the former, and fills up a file. Neither of these alloys was acted on by boiling with acetic acid for half an hour, and standing in the acid for twenty-four hours longer, nor had salt water any action upon them; hence, they may be useful for some kinds of utensils.

Dr. Stolzel adds another to the many receipts already given for staining wood of a brown colour. He first of all paints over the wood with a solution made by boiling one part of catechu (cutch or gambir) with thirty parts of water and a little soda. This is allowed to dry in the air, and then the wood is painted over with another solution made of one part of bichromate of potash and thirty parts of water. By little differences in the mode of treatment, and by varying the strength of the solutions, various shades of colour may be given with these materials, which will be permanent, and tend to preserve the wood.

We have recently seen notices of the extended use of alkaline silicates in Germany for the preservation of building materials, both stone and wood. The latter application may be noticed here with the remark that such a fire as that which recently occurred at Charing-cross Station could not have happened if the woodwork had been protected by the means noticed. The cost is but small, and the immunity it gives from fire is complete. According to the expired, and almost forgotten, patent of De Wylde, the woodwork is first saturated with a very dilute solution of silicate of potash, as nearly neutral as possible, and when this has dried, one or two coats of a stronger solution are given. When lives are lost by fire almost daily, it seems strange that such means of protecting wooden staircases and flooring should be neglected.

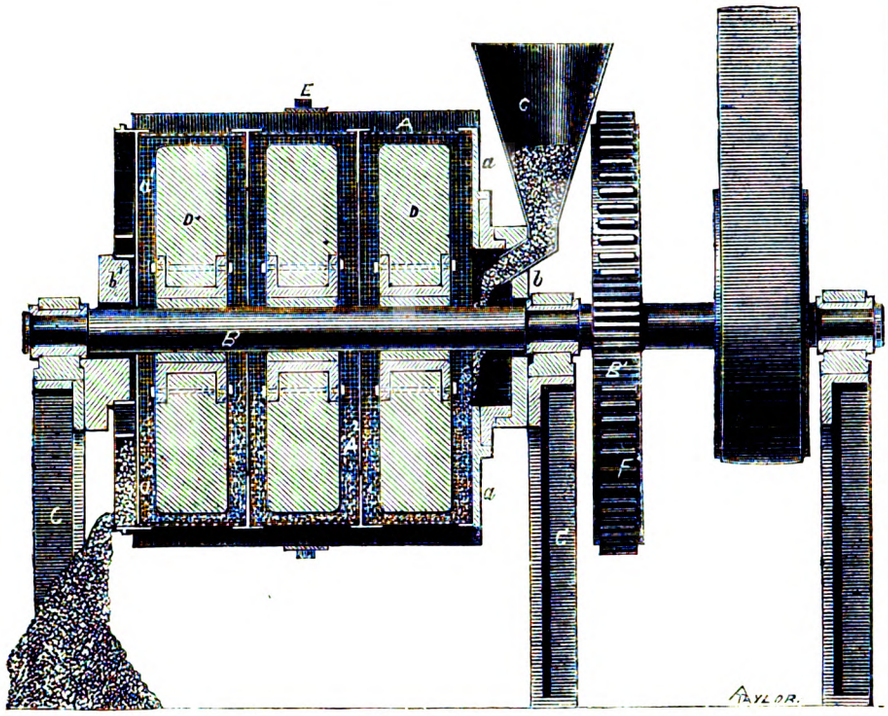
We have before mentioned Soret's cement, which is formed by making oxide of zinc into a paste with a solution of chloride of zinc. This paste quickly sets into a hard mass, which may be applied for stopping teeth and a variety of useful purposes. Dr. Tollens gives a cheaper form of the same cement, which may be used for stopping cracks in metallic apparatus, and cementing glass, crockery-ware, and other materials. He mixes equal weights of commercial zinc white and very fine sand, and makes the mixture into a paste with a solution of chloride of zinc having the density 1·26. The mixture sets rapidly, but allows plenty of time for its application. As it resists the action of most agents, it will be very useful in the chemist's laboratory.

A report, by M. Dumas, on Mallett's process for obtaining oxygen and chlorine on the large scale, which we described at page 128, vol. 86, deserves

Digitized by Google

MACHINE FOR CLEANING GRAIN.

BY MR. A. MATHER.



notice, since it completely confirms the statements of the inventor. We refer our readers to the place mentioned for a description of the process, and need only say here that, according to M. Dumas, 100 kilogrammes of protochloride of copper can be made to yield daily from 15 to 18 cubic metres of pure oxygen, at a cost of from 50 or 60 centimes. Quite as successful results were obtained in the separation of chlorine from hydrochloric acid. The same amount of protochloride furnished chlorine for the daily production of 300 kilogrammes of chloride of lime. We hope the process will be adopted for utilizing the vast quantity of hydrochloric acid evolved from our soda works, and now, for the most part, wasted.

MACHINE FOR CLEANING GRAIN.

MR. ALEXANDER MATHER, of Edinburgh, has recently patented a novel arrangement of machinery which with slight modification is applicable as a wheat cleaner or as a barley mill. The accompanying engraving shows a longitudinal vertical section taken through the centre of the machine. A is a wire cylinder closed by end plates a a' of cast iron, and mounted concentrically with and turning on a horizontal shaft B. This shaft turns in bearings carried by the cast-iron standards C. Within the cylinder, and concentric therewith, are mounted three Newcastle millstones D D D; the number may vary according to requirements. These stones are made fast by cross bolts to metal centres which are keyed to the horizontal shaft. The cylindrical casing is strengthened externally by transverse bars A', and the space between the stones is divided for a certain depth by flanged rings A^2 which also serve to strengthen the cylinder, and form, as it were, bridges for the grain under operation as it accumulates in the cylinder to ride over in its progress to the discharging end of the cylinder. At its centre the cylinder is girt with a ring of spur teeth E, through which it receives a slow rotary motion. This ring of teeth gears into a pinion keyed to a second horizontal shaft mounted in bearings on the standards C and parallel to the shaft B. A rapid rotary motion is transmitted to the stones through a band pulley keyed on one end of the shaft B, and a spur pinion B' on this shaft gives motion through a large spur wheel to a spur pinion which drives the wire cylinder.

The end plates a a' of the cylinder are fitted to bearings b b^1, made fast to the standards C C. The end plate a is cast with a large central circular opening, and this opening is covered by a fixed bearing b, which has a central hole to allow of the free passage through it of the shaft B. Another opening is made in this fixed bearing to receive the spout of a hopper c. Grain is supplied by a constant feed to the cylinder from this hopper, the grain entering through the plate a and falling to the bottom of the cylinder. Here it is subjected to great friction between the periphery of the first stone and the cylinder, and as the grain accumulates it will rise above the edge of the first ring A^2 and riding over it will come under the action of the second stone, from which it will pass in like manner to the third stone, till it meets one of a set of discharge openings in the end plate a' of the cylinder. During this progress of the grain the dust or earthy matters are first removed and discharged through the meshes of the cylinder. A portion of the husks is then in like manner discharged and in a marketable condition, and the grain passes out at the discharging end of the cylinder in a clean state.

The end plate a' is fitted with adjustable shutters which slide in grooves provided to receive them, and are held in position by means of adjusting screws. These shutters serve to contract the discharge openings to any required extent, and thereby to regulate the discharge of the cleaned grain from the rotating cylinder. The time which the grain will take to pass through the machine will depend upon the speed of discharge permitted, and this being determined by the size of the discharge openings the amount of friction to which the grain is subjected may be regulated with nicety and with the greatest facility. For operating upon barley, which is a harder grain than wheat, a more extended rubbing surface will in general be required. This may be obtained by lengthening the cylinder and adding one or more millstones to those used for cleaning wheat; or by contracting the delivery openings, and thus keeping the grain longer under the action of the stones, the required effect will be produced.

One of these machines has been at work for several months past, giving excellent results. It is in use for cleaning wheat at the steam mills, Musselburgh, near Edinburgh. The proprietor of these mills states that it cleans the wheat very effectually, breaking the sand balls, which we believe is not easily accomplished by other machines. Several more of these machines are about to be set to work, and its efficiency will doubtless lead to its wide adoption.

ON THE DRYING OF STEAM BY WIRE-DRAWING, AND ON ITS LIQUEFACTION BY EXPANSIVE WORKING.*

BY W. J. MACQUORN RANKINE, C.E., LL.D., F.R.SS.L. and E.

THE following is a summary of Dr. Rankine's mathematical theory of this subject, and which forms an appendix to the paper we published last week:—

1. The "Thermodynamic Function" for a given substance in a given condition is a quantity which has the following properties—when the substance undergoes any change of dimension and temperature without communication of heat from or to other bodies the thermodynamic function is constant; and when such communication of heat takes place the change in the value of the thermodynamic function is equal to the dynamic equivalent of the heat received or given out, divided by the absolute temperature at which the change takes place, and is positive when heat is received and negative when heat is given out.

In symbols, let ϕ denote the thermodynamic function, $d\phi$ the change of its value, t the absolute temperature, and dQ the dynamic equivalent of the quantity of heat received by the substance; then

$$dQ = t\,d\phi; \quad . \quad . \quad . \quad . \quad . \quad (1)$$

and this is the general equation of thermodynamics. When there is no communication of heat ϕ = constant, and $d\phi = 0$.

2. For a substance which consists of unity of mass of a given fluid, partly in the state of liquid and partly in the state of vapour, the value of the thermodynamic function is as follows:—

$$\phi = \int \frac{K\,dt}{t} + (1-m)(v-v^1)\frac{dp}{dt}; \quad . \quad . \quad (2)$$

in which K is the dynamical value of the specific heat of the substance in the liquid state, m the fraction of the whole mass which is liquid, $1-m$ the fraction which is in the state of vapour, v the volume which the whole mass would occupy if it were wholly in the state of vapour, v^1 the volume which it would occupy if it were wholly in the liquid state, and $\frac{dp}{dt}$ the rate at which the pressure varies with the boiling point.

3. Let the suffixes 1 and 2 denote the values of the various quantities in the formula (2) at the beginning and at the end of the expansive working of the mass of fluid in question in a non-conducting cylinder. Then we have

$$\phi_1 - \phi_2 = 0;$$

and consequently,

$$\int_{t_2}^{t_1} \frac{K\,dt}{t} + (1-m_1)(v_1 - v_1^1)\frac{dp_1}{dt_1} - (1-m_2)(v_2 - v_2^1)\frac{dp_2}{dt_2} = 0; \quad . \quad . \quad (3)$$

an equation which gives the means of determining m_2 when the other quantities are given, and thus of ascertaining whether, and to what extent, the fraction of fluid in the liquid state will be increased at the end of the expansion.

4. By the following modifications the equation (3) is brought into a simpler form, which is approximately applicable in most cases that occur in practice. If the specific heat of the liquid can be treated as approximately constant the first term of equation (3) becomes approximately

$$K \text{ hyp. log. } \frac{t_1}{t_2}.$$

The factor $(v - v_1)\frac{dp}{dt}$ represents, according to the principles of thermodynamics, the quotient of the latent heat of evaporation (in units of work) divided by the absolute temperature. For many fluids the latent heat of evaporation can be expressed approximately by

$$a - b\,t,$$

a and b being two constants; and thus equation (3) becomes approximately

$$K \text{ hyp. log. } \frac{t_1}{t_2} + (1-m_1)\left(\frac{a}{t_1} - b\right) - (1-m_2)\left(\frac{a}{t_2} - b\right) = 0; \quad . \quad . \quad . \quad (4)$$

whence we obtain the following formula for the fraction of the mass of fluid which is in the liquid state at the end of the expansion—

$$m_2 = 1 - \frac{K \text{ hyp. log. } \frac{t_1}{t_2} + (1-m_1)\left(\frac{a}{t_1} - b\right)}{\frac{a}{t_2} - b}. \quad (5)$$

If the vapour at the beginning of the expansion, though saturated, is dry, m_1 is to be made = 0.

5. The values of the constants for water and steam are as follows:—

K = 772ft. per deg. of Fah., or 424 metres per deg. Cent.

a = 1,110,000ft., or 338,000 metres.

b = 540ft. per deg. of Fah., or 294 metres per deg. Cent.

The absolute temperature is found by adding 461 to the temperature on Fahrenheit's scale, or 274 to the temperature on the Centigrade scale.

6. When the expansive working corresponds to an indefinitely small fall of temperature $-dt$, equation (3) leads to the following differential equation:—

* From "The Engineer."

Digitized by Google

$$\frac{K}{t}+(1-m)\frac{d}{dt}\left\{(v-v')\frac{dp}{dt}\right\}$$
$$-\frac{dm}{dt}(v-v')\frac{dp}{dt}=0; \quad . \quad . \quad . \quad . \quad (6)$$

which, by making the substitutions mentioned in Article 4, takes the following approximate form:—

$$\frac{K}{t}-(1-m)\frac{a}{t^2}-\frac{dm}{dt}\left(\frac{a}{t}-b\right)=0; \quad . \quad (7)$$

consequently,

$$\frac{dm}{dt}=\frac{Kt-(1-m)a}{at-bt^2}, \quad . \quad . \quad . \quad . \quad (8)$$

and according as this expression is negative or positive an indefinitely small extent of expansive working is accompanied by liquefaction or by drying.

7. The approximate rules for steam in the body of this communication were deduced from the results obtained by calculating a number of examples by means of the formulæ explained in this appendix. W. J. M. R.

Glasgow University, February 17.

MANUFACTURE OF BEET-ROOT SUGAR IN THE UNITED STATES.

By Mr. John Bimbeck.

THE manufacture of beet-root sugar has lately undergone considerable discussion in the daily papers. The following article upon the subject, from the "Journal of the Franklin Institute," may, therefore, prove interesting, as throwing a light upon the position of the question in America:—

Feeling a deep interest in all that relates to the successful progress of American industry, the writer was induced, during a late trip to the West, to make a visit to the beet-root plantation and sugar manufactory established at Chatsworth, Illinois. Chatsworth is a village of some 800 inhabitants, located in Livingstone County, on the line of the Toledo, Peoria and Warsaw Railway. The direction of this railway is east and west, connecting at Gilman, fifteen miles east of Chatsworth, with the Chicago branch of the Illinois Central Railway, at Chenoa, twenty-two miles west, with the Chicago, St. Louis and Alton Railway, and at El Passo, thirty-seven miles west, with the main line of the Illinois Central Railway. This location is on the prairie land; the marked feature of the country being its level surface, unbroken by either hills or trees of any size. The greater part of the land is uncultivated, and is covered with prairie grass.

The plantation and works of the Germania Sugar Company are located at the south-east corner of the village. They have 2,500 acres of land, 550 of which have been planted this year with the sugar-beet, and the balance with corn, oats, and hay. The refinery is located near the railway track, and consists of main buildings of wood, which contain the machinery proper, and several other frame buildings, used as storehouses and stables. The enterprise was started some four years since by the brothers Gennert, of New York, but has since been made a stock company, the members of which are all residents of the West. The planting is done in April, and the beets harvested in October, at which time the manufacturing commences and continues until March. On harvesting, the beets are piled in trenches in the fields for protection from the frosts, enough being taken each day to supply the working capacity of the refinery. The machinery was transported from Germany, and has a capacity for working sixty tons of beets in twenty-four hours.

The first process is the washing of the beets, and for that purpose is used a cylindrical vessel four feet diameter by ten feet long, its circumference or shell made of wooden slats placed longitudinally, with alternate openings between them. This drum is placed at an angle of 10deg., both ends are opened, the beets thrown into the higher end, and the drum slowly revolved by appropriate gearing in a water-tank of sufficient depth to bring the water-line midway between the axis and lower edge of drum. The interior of the drum is provided with a spiral screw and angle pieces, which give the beets a continual movement through the water towards the lower end, the earthy matter being washed off and passing through the openings between the slats into the tank below. The beets are discharged from the lower end on a revolving table some 12ft. in diameter, around which are placed women and boys, who remove all the diseased and defective ones, and prune off all the useless parts. The perfect beets are thrown into the buckets of an elevator near at hand, and discharged into a hopper on the floor above, which delivers them to two rasping or pulping machines. These machines are simple, and consist of revolving drums about 2ft. diameter by 2ft. long, the circumference being provided with projecting saw-blades set at a slight angle with their axis, the blades being parallel with each other, and about 2in. apart. The drums are revolved with great rapidity inside of close cases, and water to the amount of ten per cent. of the weight of the beets is introduced continuously during the operation. The discharge is a fine pulp, delivered into a traveling bucket, in front of ten centrifugal draining machines, which are placed on an intermediate floor midway between the first and second floors.

The charge for each centrifugal is 200lb. of pulp, in which 20lb. of water has been added during the rasping process, making 220lb. in all. The centrifugal drum is then revolved some 1,500 revolutions per minute, thirty-five per cent. additional water being introduced during the process. The juice evolved in the operation is conducted from the centrifugals by canals to a line of six defacators, each of 300 gallons capacity, while the dry pulp is removed from the interior of the drum for the use of the cattle as fodder. The defacating process is the same as pursued with sugar cane juice, excepting that an excessive quantity of lime is used for neutralizing the acids. Below each defacator is an upright cylindrical vessel made of wrought-iron plate, of about 600 gallons capacity. These vessels are provided with heating worms at their bottoms, and covers with hinges on top. The clear juice of each defacator is discharged into the corresponding vessel below it. The scum arising from the defacation is subjected to the action of scum presses, by which the syrup remaining is made available.

The lime employed in the defacation is removed by the action of carbonic acid gas, which is forced into the liquor while in the vessels below the defacators, by means of a steam pump. The gas is manufactured in a lime kiln, on the premises. On admitting the gas into the juice, the latter froths very much, which accounts for the necessity of having the receiving vessels of double the capacity of the defacators. On the decomposition of the lime, the supply of gas is stopped; the liquor is then heated to the boiling point, and by means of a monte-jus elevated to a tank above the filters. The deposit in the vessels, after the drawing of the liquor, is also subject to the action of the scum presses.

The filters are six in number, and of the bone-black variety, about 30in. in diameter by 30ft. high. Three of them are used for the first filtration. After leaving these filters, the liquor is carried to a series of three evaporators. They are plate-iron vessels about 8ft. diameter, by 4ft. deep, provided with a copper coil or worm at their bottoms. Steam is admitted into the coils and the liquor concentrated to about 26deg. B.; the scum arising during the boiling is also subjected to the action of the presses. From the evaporators, the juice is elevated by a second monte-jus to a tank above the second set of filters, and after this second filtration, passes to a vacuum pan, and is boiled down to the crystallizing point. Five centrifugal machines are employed for the purging operation. The sugar discharged from the vacuum pan is carried to a mixer, located on the floor above the five centrifugals; the mixer discharges into a travelling bucket arranged for supplying all the centrifugals.

The first product of this operation is a beautiful white sugar of heavy grain, ready for the drying tables and the market. The syrup evolved during this operation is re-boiled in the vacuum pan, and re-worked in the centrifugals, making a fair brown sugar. The refinery is supplied with the ordinary washers and ovens for re-washing and revivifying the bone-black. Steam is supplied by four 40in. by 30ft. double flue boilers, and two 60in. by 30ft. boilers, the two latter each containing five flues. The fuel used is coal; it is not of very good quality, but is to be had in abundance, one shaft being worked in the village. The price is about ten cents per bushel.

This, like most new enterprises, has met with its discouragements. The first attempt at sugar making on a large scale, was made during the autumn of 1866, and winter of 1867. Some of the machinery proved defective, and it was found impossible to obtain the requisite steam on account of deficiency of boiler power, and the want of a proper smoke-stack. The beet crop was an abundant one, averaging some fifteen tons per acre, and would have required four and a-half months working of the refinery to manufacture into sugar, at an average of sixty tons per day; owing to the defects mentioned, not near this quantity was reached, and, as a consequence, tons of beets had to be carted and thrown away to make room for the spring planting. Although the enterprise proved a failure in a pecuniary point of view, yet the cause was plainly seen to have been a remediable mechanical one. The product per acre proved the land to be well adapted to the culture of the beet, while the operation of the refinery, giving eight per cent. of sugar, compares favourably with the best results in Europe.

During the past summer, additional boiler power was placed, and other defects remedied, and those interested had every reason to hope that this present season would give a rich reward for all the energy, perseverance, and patience they had displayed. Unfortunately, this will not be the case, as this last has been the dryest season experienced in the West for a period of thirty years. No rain of any consequence has fallen since June, and the beet crop has proved a failure. It has been gathered, and gives an average of only three tons per acre, instead of fifteen, as on the previous year. The season has been an exceptional one in Illinois, and the effects o the drought has been very serious. Most of the wells have failed, cattle have been, and are dying from thirst, and the Illinois Central Railroad is carrying water from Chicago down their road for the use of their locomotives. Such a season may not again be experienced for many years. Notwithstanding these discouragements, there can be no doubt of the final success of the enterprise. Persons who have lived in the State some twenty years, and are familiar with its characteristics, assert that good crops of beets can be had at least nine years out of ten. The Messrs. Gennert have proved the feasibility of extracting the sugar in such quantities that there will be left a good margin of profit. They are the pioneers in this country of an enterprise which will eventually prove one of the most important elements of public prosperity. The enterprise can be carried on profitably in nearly all of our Northern States,—those which can offer the advantages of cheap land, cheap labour, coal, lime, water, and a ready market are, of course, to be preferred. As there can be no doubt in regard to our possession of the above facilites, then the only question to ask is, have we the engineering and mechanical skill to design and construct the proper machinery for the manipulation of beet-root into sugar, and the enterprise to engage in and carry forward the project to a successful result? In regard to the machinery, the question can be satisfactorily answered. Nearly all the parts required are precisely similar to those manufactured in this city during the past twenty-four years for Louisiana, Cuba, and South America, for making sugar from cane juice, the only difference being in the pieces used for extracting the cane juice and beet juice, respectively. At Chatsworth, the evaporating is done in open kettles, which is an expensive mode, so far as fuel is concerned, and is also destructive to the colour of the liquor. In Germany, in the best refineries, vacuum pans of treble effect are used for evaporating, three being generally employed. They are placed near each other on one common platform, the first being worked by the exhaust steam of the different steam engines in the refinery, the second by the vapours of the boiling liquor of the first, and the third, or strike pan, by the vapours of the second. The economy of this plan is self-evident, while the low temperatures required for boiling, as well as the absence of exposure of the liquor to the atmosphere, prevents the deleterious effects noticed by the use of open kettles. This system had its origin in this country, and has been most successfully practised for many years in Louisiana, Cuba, and South America, in the evaporation of cane juice.

The enterprising spirit required surely cannot be wanting. There has never been a lack of it in this country, and I feel sanguine that many years will not elapse before all the sugar consumed in the country will be of domestic growth and manufacture. The importance of getting all the saccharine matter from the raw beet has resulted in many devices for its extraction. In Europe are employed for that purpose hydraulic presses, centrifugals, cold maceration, and what is called the "Diffusion Process." The centrifugal process has been considered as best adapted for the purpose in this country, requiring but little labour in working, while the per centage of juice has been good, as compared with the other modes.

A beet-root plantation and refinery is about being started at Aurora, near Chicago, Illinois, and is to be worked on the diffusion principle. Those interested claim a gain of 1¼ to 1½ per cent. of sugar over every other mode, with less labour, and that the refuse or pulp is better as food for cattle. European capital will be employed in this enterprise, and as Congress has exempted from duty all machinery needed in the manufacture of beet sugar, the major portion will be imported, while our own steam engine and machine establishments, capable of doing the whole work, are suffering for want of orders.

NEW USES OF PAPER.

ONE of the latest uses of paper is its application in the manufacture of pails, wash-basins, pans, spittoons, &c., and, observes an American paper, strange as it may seem, it is nevertheless true that the above articles, as made by the Papier-mache Manufacturing Company, of Greenport, L. I., from a chemically prepared paper, are superior in many respects to any others ever before made. The paper from which these articles are manufactured is rendered impervious to the action of water or acids; the utensils can be placed in an oven until the water will boil in them; placed in the sun at the hottest season, or exposed to the severest cold, without the slightest effect on them; where wood would rot and iron would rust, these articles are unaffected, and, with proper usage, would be as good as new. In pails there is an advantage that water will not taste of the material, and will never soak and will never fall to pieces; they are lighter than the wooden pail, and being a non-conductor of heat, will keep water cool. The articles are coated with a vegetable composition, which, even if it does wear off, does not affect their durability, and does not injure them, except in appearance.

COMBINED PORTABLE PUMPING ENGINE AND BOILER.

BY MESSRS. BROWN AND WILSON.

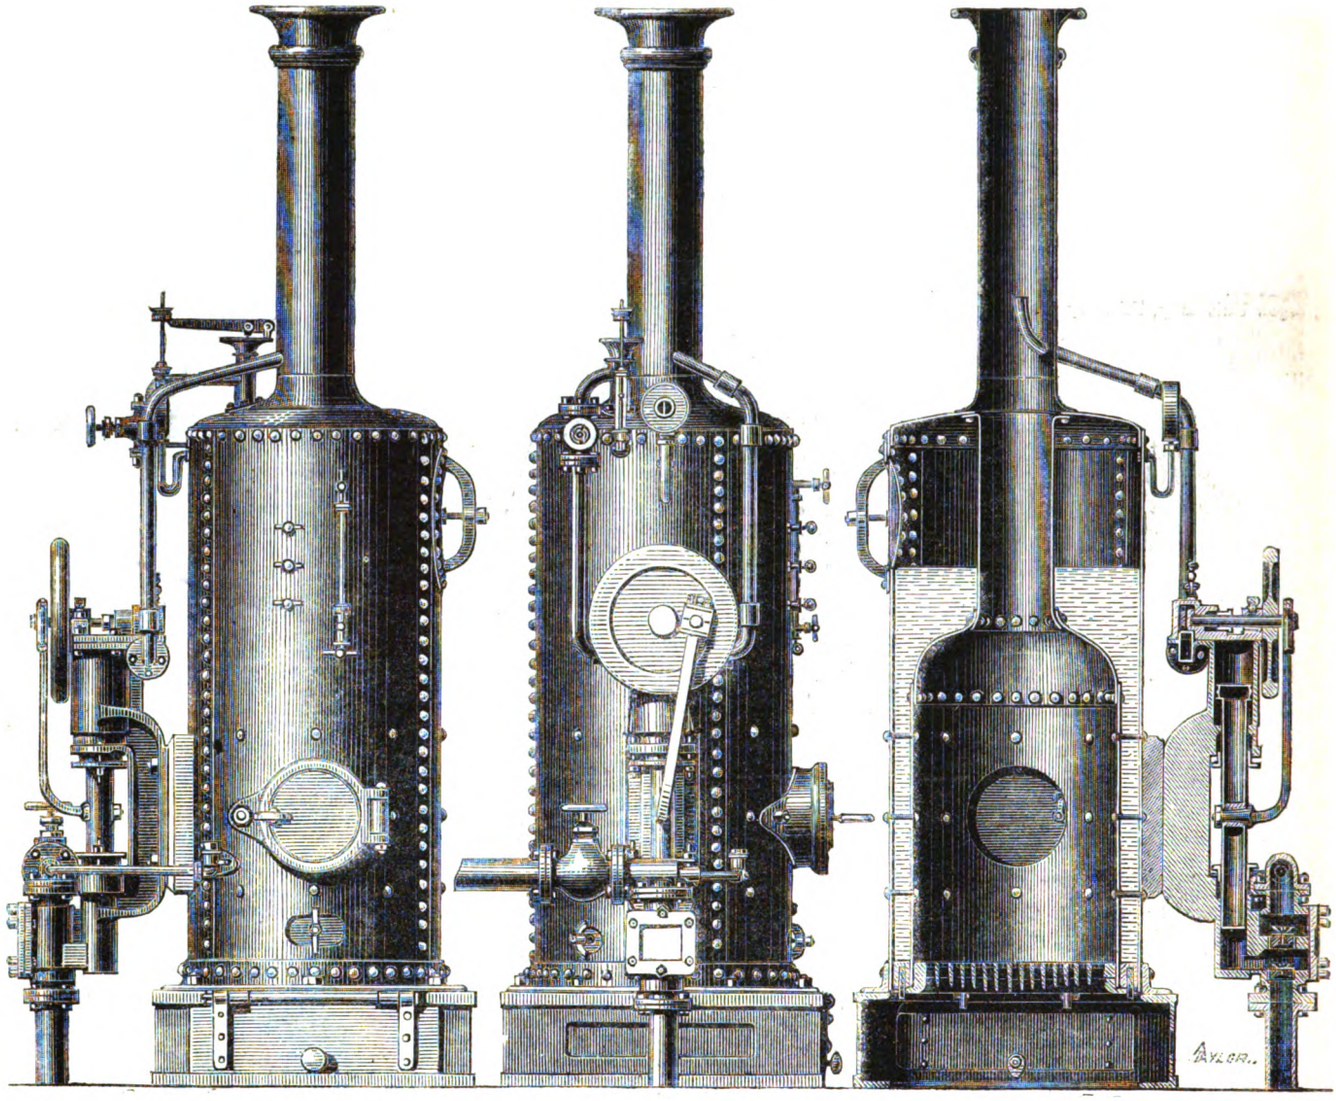

FIG. 1. FIG. 2. FIG. 3.

COMBINED PUMPING ENGINE AND BOILER.

THE engine represented in the accompanying engraving is attached to the boiler by its back; both are shown in side elevation in fig. 1, front elevation fig. 2, and in vertical section (on centre line of fig. 2) at fig. 3. The engine and pump are cast together, and are bored out together at the same operation, and with one bar. The pump, ram, piston, and rod, as will be seen, are in one piece, having at the centre of the ram a conical bearing, and at the small end a steel plate is dovetailed in, upon which the steel nut of the connecting rod works. The glands are also of gun metal, and the valves are of india-rubber working upon brass gratings for pressures up to 40lb., but above that pressure they are of the three-feathered description of clacks. Access is had to both suction and delivery valves by the door, as shown in fig. 2, and that without disturbing any pipes. The fly-wheel, shaft, and gear, for working the slide valve, are all carried upon the cylinder cover, so that the cylinder valve, face, and crank, for working the valve, can be at once inspected by removing the cover, and without disturbing any pipes or joints. The slide-valve is constructed with horns upon its back, which permit, by a sliding steel block, the vertical motion of a small crank, while the lateral motion is transmitted to the slide-valve. This crank is screwed and pinned on to the steel crank shaft, which passes through a stuffing box in front of the valve casing, and thence through the front journal, terminating in the wheel. In the face of the latter the crank pin is fixed, and the connecting rod having one end working in the centre of the ram, with the conical adjustment for wear, is bent out of the line of the engine some few inches, and lays hold of the crank pin in the face of the wheel. Exception might be taken to this rod on account of its curved form, but the fact is, assuming that the bend is rigid (and it is so, because there is so much metal put in it whilst the work done is so exceedingly small), there being an unyielding cantilever, and working in the centre of the ram, it is practically equivalent to working directly from that centre upon the crank pin. When we say practically so, we wish it to be understood that the work performed by the steam is not in causing a wheel to revolve, but a piston to reciprocate; consequently, the strain exists entirely between the cylinder and pump, and is resisted by the piston, rod, and ram.

The boiler, as will be apparent to most engineers, is one of the simplest construction, and only requires to have a few of its leading qualities pointed out. The firebox is a plain cylinder, with dome top stayed all round; this, with many, may appear superfluous, but when the box wears thin and oval the stays are a great security to the boiler; in fact, a firebox $\frac{1}{8}$in. thick will work, if properly stayed, and if it does fail it will be at one of the stays, and so it will drown out the fire and save a more serious accident. The top of the boiler is flat. Some vertical boilers are made with a dome top, but they never last long, this being on account of the greater heat of the firebox than the outer shell; consequently, a greater elongation from expansion of the box and flue than the outer shell, which eventually breaks the flue away at the neck next the box, unless the top is flat, or nearly so, and thus acts as an expansion joint. The fittings upon the boiler are those usually specified in good boilers, and the feed water is supplied from a small branch from the pump. We are informed by Messrs. Brown, Wilson, and Co., of the Vauxhall Ironworks, London, who have furnished us with the drawings from which our engraving is prepared, that 350 of these engines were sent out by them during the last year.

THE SOCIETY OF ENGINEERS.

AT the meeting of the Society of Engineers, held on Monday the 2nd inst., Mr. Baldwin Latham, President, in the chair, a discussion took place on Dr. Cullen's three papers. On the proposed lines for a Ship Canal "between the Atlantic and Pacific Oceans," "on the Panama Railroad," and "on the Darien Ship Canal." The following candidates were balloted for, and duly elected, viz.:—As member, Mr. Arthur Rigg, jun., of Chester. As associates, Mr. Francis Michael Cotton, Foules-terrace, Mr. Edwin Latimer Rumble, Maismore-square, Mr. Stephen Wurr, Victoria-road, Stoke Newington, and Mr. William Hart Cullen, New Malden, Surrey.

A NEW spring of naphtha has just been discovered at Koudako in the valley of the Kouban, in Caucasus. The jet rises from a depth of 274ft. below the surface of the ground, is 4in. in diameter, and ascends to a height of 40ft. The yield is said to be 6,000 pailfuls per day.

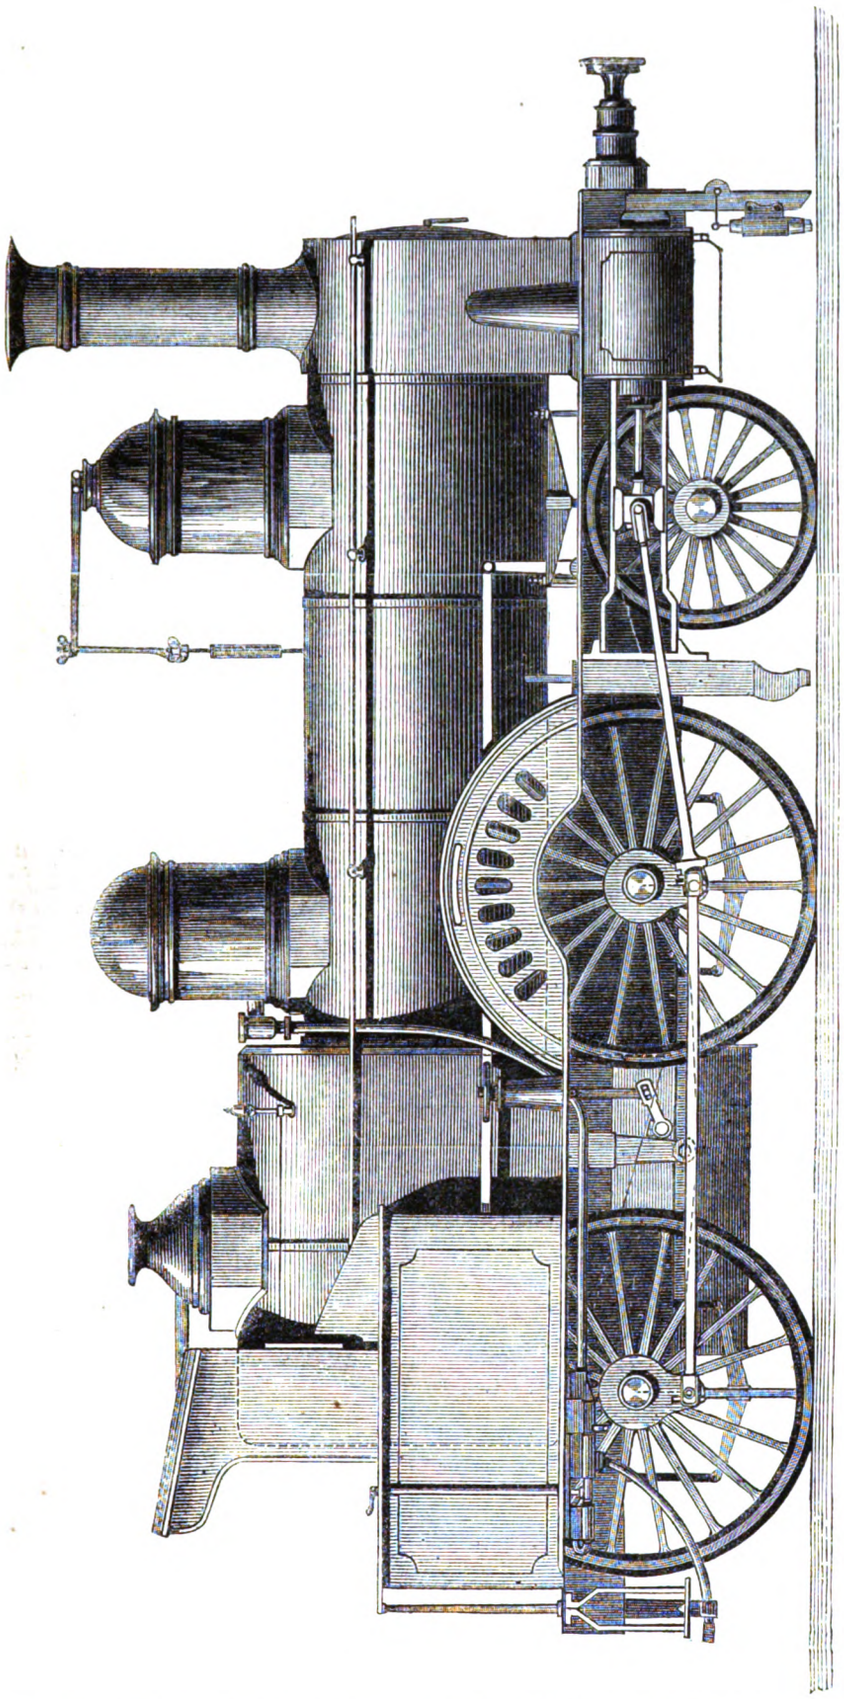
FAST PASSENGER ENGINE—BERGISCH MARKISCHE RAILWAY, PRUSSIA.

BY M. BORSIG.



FAST PASSENGER ENGINES—BERGISCH-MARKISCHE RAILWAY, PRUSSIA.

THE engine illustrated in the annexed engraving is one of several built by Borsig, and working the fast passenger traffic on the line from Dusseldorf to Dortmund, passing through Elberfield and Witten. The gradients on this railway are not very favourable—inclines of 1 in 100 being frequently encountered, while grades of 1 in 140 are very numerous. Between Erkrath and Hochdale, about seven miles from Dusseldorf, there is an incline of about 1 in 40, a mile and a-half long, up which the trains are assisted by a six-coupled, banking tank engine, weighing forty tons, and built by Borsig. The mode in which this engine is used is very remarkable. The incline was formerly worked by a stationary engine, which has long since been discarded. The rope, however, is retained, and the banking engine works on the descending line, hauling the ascending train, with the assistance of its own locomotive, to the top by means of the rope running over a suitable wheel at the head of the incline. By this means the gravity of the banking engine is utilized, representing a gain of one ton of tractive effort instead of a ton of resistance, or virtually a clear gain—minus the friction of the rope—of two tons of tractive effort. What proportion of this is realized after the friction of the rope is deducted we are unable to say—unless the gain be considerable it is unlikely that the rope would be retained.

The fast passenger engine we illustrate—the 1,781st built by Borsig—presents many points of difference from English practice, as will be perceived not only from a glance at the engraving, but from the following description:—Beginning with the principal dimensions, we find that the engine has 16in. cylinders, 22in. stroke, and four coupled driving wheels, 6ft. in diameter. The barrel of the boiler is about 3ft. 10in. in diameter inside, and nearly 14ft. long. The tubes are of iron, 180 in number and about 2⅜in. diameter outside. The inclined grate is 6ft. 2in. long, and about 3ft. wide, presenting about 18½ square feet of area. The heating surface of the firebox is about 80ft., and of the tubes about 1,020ft., or, in all, 1,100ft. The safety valves are loaded to 112lb. per inch. The weight is distributed as follows :—Leading axle, eleven tons; driving wheels, eleven tons; trailing wheels, eleven tons; total, thirty-three tons. It will thus be seen that the engine is heavy for the dimensions of the cylinders—a fact mainly due to the great size of the boiler rendered necessary in some degree by the use of slack coal. The upper part of the firebox shell rises to a great height above the barrel in order to provide steam space and room for the immense bridge stays supporting the firebox crown, which are 6ft. 2in. long and 10in. deep at the middle. We may add that the firebox is put in from the top before the outer shell is riveted up. The bridge stays are each connected to the crown by four sling stays, and the firebox shell is further strengthened by horizontal stays running right across.

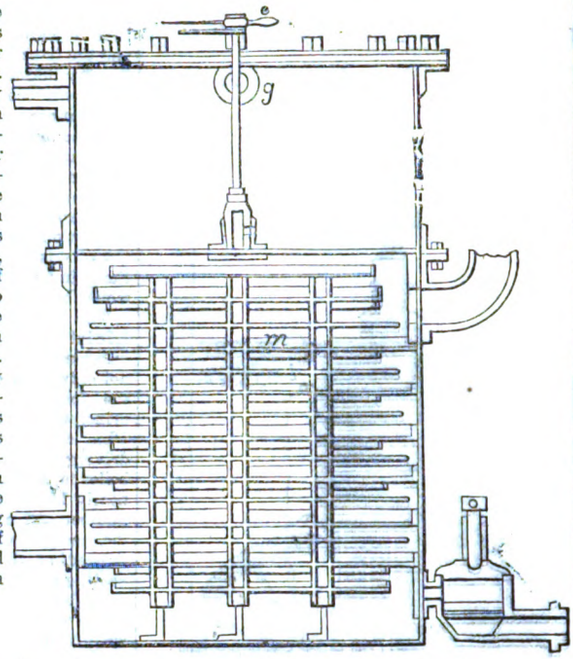
Although two domes are seen, but one, that next the smokebox, is used as a steam chamber. It is placed in communication with the space above the firebox by a pipe, and contains the regulator valve. The other dome contains Wagner's apparatus for purifying the feed water sent to the top of the dome by the injectors. This apparatus has been used in the Bergische-Märkische line since 1863, with good results. In the annexed engraving we give a section of one form of the apparatus to illustrate the principle on which it acts. The water is fed in at the top, and, falling on a series of trays or partitions *m*, passes downward depositing sediment which would otherwise find its way to the boiler. The water, being highly heated by the steam within the dome, can no longer retain the sulphate of lime and magnesia in solution, and they are therefore thrown down. The trays are removed from time to time as they become foul and cleaned. The injector is of rather peculiar construction, the steam cone valve is suppressed altogether, and the water cone is moved by a cam worked by a handle from the foot plate. The injectors are disposed horizontally in a position found to be very convenient. They are made wholly of cast iron.

The springs of the coupled wheels are placed below the axles, their ends being connected by compensating levers. The springs of the leading wheels are coupled by a transverse compensating beam, so that the engine virtually rests on three points of support. The coupling and connecting rods are of Borsig's cast steel, rivalling that of Krupp in excellence; they are exceedingly light. The dimensions, measured on the engine, are as nearly as possible as follows:—Connecting rod, small end, depth, 2in.; thickness, 1 2-5in.; large end, depth, 3in.; thickness, 1 2-5in. The coupling rods, 8ft. 5in. long centre to centre, are but 2in. deep by 1 2-5in. thick at the smallest place, and 3 1-5in. by 1¼in. at the centre. The crank pins in the driving wheels are 3½in. in diameter, and in the trailing wheels 2½in. These are all extraordinarily light dimensions for an engine with 16in. cylinders, yet we believe that the line is nearly exempt from accidents due to the breaking of coupling rods.

As already stated, the fuel used is slack, which is of good quality, coming from the Ruhr district. The distance between the grate bars is not less than ½in. to ¾in. At first sight it would seem that on such a grate it would be impossible to burn slack without great waste. The system of working

Digitized by Google

disposes of this objection. The fire is lit with large coal, and slack is subsequently fed on mixed with water to the consistence of thick mortar. The fuel quickly cakes, and may then be broken up, burning with little waste. Many sparks are produced, however, and to prevent their escape up the chimney, a very singular expedient is employed: a fine jet of spray from the boiler is thrown into the smokebox. The plan is generally used, with good results, on the German lines. A number of fast passenger engines very similar to that described were put on the line in 1863, but the intervals between the axles being respectively 6ft. 8in. and 7ft. 9in., the load was unequally distributed, the leading wheels carrying twelve tons, the driving wheels eleven tons, and the trailing wheels ten tons. This defect has been removed in the present series put on the line in 1865, by bringing the driving wheels nearer to the leading wheels. Mr. Stampte is the chief engineer of the line, the general management of which reflects much credit on him.



TECHNICAL INSTRUCTION.

THE Lords of the Committee of Council on Education have approved of the publication of the following Explanatory Memorandum to accompany their Minute of 21st December, 1867. This Memorandum shows fully the aid which the State affords in promotion of Technical Instruction at the present time.

1. It will be seen that this Minute creates three descriptions of scholarships or exhibitions for the encouragement of Science Instruction and for the support of students of the industrial classes while continuing their education. These are intended to supplement and enlarge existing action on the part of the Science and Art Department, and to promote secondary instruction in elementary schools, thus forming a connecting link between them and the Science and Art schools and classes.

2. The existing action through the Science and Art Department is to aid instruction in Science in the following subjects:—1, practical plane and solid geometry; 2, machine construction and drawing; 3, building construction or naval architecture and drawing; 4, elementary mathematics; 5, higher mathematics; 6, theoretical mechanics; 7, applied mechanics; 8, acoustics, light, and heat; 9, magnetism and electricity; 10, inorganic chemistry; 11, organic chemistry; 12, geology; 13, mineralogy; 14, animal physiology; 15, zoology; 16, vegetable physiology and economic botany; 17, systematic botany; 18, mining; 19, metallurgy; 20, navigation; 21, nautical astronomy; 22, steam; 23, physical geography. And in Art in Elementary Drawing as an education of the power of observation and in drawing, painting, modelling, and designing for manufacture and decoration.

3. In order to place a school or class in connexion with the Science and Art Department, it is necessary that a committee, consisting of at least five persons, should be formed, who will undertake certain duties of superintendence in connexion with it.

4. As respects Science, the aid consists of—(1) payments to the teachers on the results of instruction as tested by examination, (2) medals and prizes to the successful students, (3) grants to the school in aid of the purchase of apparatus to the extent of 50 per cent. of the cost, and (4) Royal Exhibitions and free admissions to the Royal School of Mines in London and the Royal College of Science in Dublin.

5. The payments to the teachers vary from £1 to £5 according to the class in which the student is placed. There are five classes, the fifth being the lowest. The payments are only made for the instruction of students of the artizan or weekly wages class, and those whose incomes are less than £100 per annum. The teacher to be qualified to earn payments on results must have taken a 1st or 2nd class, unless he has obtained some University degree.

6. The examinations are held in May. The examination in each subject is held over the whole kingdom on the same night. It is not necessary to enable a class to be examined and obtain prizes, &c., that the teacher should be certificated. If a satisfactory committee be formed, any class or single student can be examined, however taught.

7. Prizes, which, with some few restrictions, are open to all students, are given to those who obtain a 1st, 2nd, or 3rd class. To the best in each subject are given a gold, a silver, and two bronze medals.

8. Six Royal Exhibitions of the value of £50 per annum, tenable for three years, are given in competition at the May examinations. Three of these are to the Royal School of Mines in London, and three to the Royal College of Science in Dublin. Free admissions are given to the courses at these institutions to all who take gold medals.

9. The detailed rules will be found in the Science Directory, published by the Department, price sixpence, which will be furnished on application to the Secretary, Science and Art Department.

10. As respects Art.—Firstly.—Towards the teaching of elementary drawing in schools for the poor.—This aid consists of payments to the managers of 1s., 2s., or 3s. on account of children satisfactorily taught drawing, and who pass a very elementary examination of the first grade; and of payments of 5s. or 10s. on children or pupil-teachers who pass the more advanced or second grade examination, and of prizes to successful children and pupil-teachers. The first grade consists of drawing in outline from flat examples, drawing from regular solids or objects of simple form, and of easy problems in practical geometry. The second grade is an examination of a higher standard than that of the first grade, but in the same subjects, with the addition of perspective and mechanical drawing. Examinations are held in May in any elementary school taught by a master holding a certificate for drawing, or who has passed a second grade examination in any of the above three subjects of drawing taught in elementary schools.

11. Secondly.—Towards art instruction in night classes for artizans held in elementary schools, in literary, mechanics', or similar institutions.—This aid consists of payments of 10s. or 15s. on account of artizans or their children above 12 years of age satisfactorily taught drawing of the second or third grades; of prizes to successful students; and of payments towards the local expenses of examination. The third grade is represented by works embracing the whole course of instruction in night classes or schools of art, such as drawing from examples, from casts or models, from nature, the antique, or the life; painting, flowers, landscape, or from life; designing or drawing for decorative purposes.

12. Thirdly.—To schools of art held in rooms entirely devoted to art instruction.—This aid consists of similar payments to those awarded to night classes, and of the following additional payments:—20s. on account of every artizan satisfactorily instructed in art, £15 or £30 on account of art pupil-teachers, £5 or £10 on account or students trained for art teachers or national scholars. £3 on account of free studentships to artizans submitting advanced works. £10 on account of expenses of annual report and examination.

13. Prizes are given to successful students, and the advanced studies of the schools of Art are brought together in a national competition, when gold, silver, and bronze medals, and other prizes, are awarded. All payments are contingent on the employment of certificated teachers.

14. Elementary schools, night classes, and schools of art are aided to the extent of 75 per cent. in the purchase of examples.

15. Fourthly.—By the maintenance of the National Art Training School at South Kensington, in which highly qualified students from local schools of art are admitted and trained as masters for schools of art or as designers, or art-workmen. Such students receive allowances for their support of from 15s. to 40s. weekly.

16. Fifthly.—Through the National Museum of Decorative Art and the National Art Library, which are made as far as possible circulating collections for the benefit of local schools of art.

17. The detailed regulations for the administration of Art Instruction are given in the Art Directory.

18. As respects Elementary Schools.—By the Minute of the 20th February, 1867, additional grants are made by the Education Establishment at Whitehall to elementary schools under inspection for instruction in subjects of secular instruction beyond reading, writing, and arithmetic. The regulations under which such grants are made are issued by the Education Establishment, Whitehall.

19. The managers of an elementary school under inspection can permit their premises to be used for science teaching provided that there be no interference with the primary purpose of the elementary school or its three attendances. A science class may thus be formed in connexion with and receiving payments from the Science and Art Department. But no payments are made to teachers on account of Science teaching in respect of any instruction in Science that may be given during the three attendances of an elementary school receiving aid from the Education Establishment, Whitehall.

20. In an elementary school not under the inspection of the Education Establishment, and, therefore, not receiving State aid to elementary instruction, science classes may be formed in connexion with the Science and Art Department without any restriction as to the time or manner in which the instruction in science may be given.

21. From this brief explanation it will be understood how the Minute of the 21st December will affect existing institutions. This Minute provides for two forms of scholarship in connexion with elementary schools whether receiving State aid as such or not. The first of these is the elementary school scholarship. £5 are granted to the managers of any elementary school for the support of a deserving pupil if they undertake to support him for a year and subscribe £5 for that purpose. One such scholarship is allowed per 100 students in the school. The selection of the student for the scholarship is to be by competition; the details of this, however, the managers of the school may arrange as they please, subject to the approval of the Science and Art Department. The payment of £5 by the Science and Art Department is made conditional on the student passing in a branch of science at the May examination.

22. The second, a more advanced scholarship, is "the Science and Art Scholarship," of which, again, there may be one per 100 students. This is granted without any corresponding contribution on the part of the locality. The Science and Art Department makes a grant of £10 towards the maintenance, for one year, of the most deserving student or students in an elementary school who have taken a first grade in Elementary Geometry and Freehold or Model Drawing,* and passed in some branch of science, on condition that, at the end of the year, the student obtains at least a third class in the subject of science in which he originally passed or passes in some other subject. In both these cases the student must be from 12 to 16 years of age.

23. Lastly, for advanced scientific instruction, the Minute offers local exhibitions to enable students to complete their education at some college or school where scientific instruction of an advanced character may be obtained. The Science and Art Department will make a grant of £25 per annum, for one, two, or three years for this purpose when the locality raises a like sum by voluntary subscriptions. And if the student attend a State school, such as the Royal School of Mines in London, the Royal College of Chemistry in London, or Royal College of Science in Ireland, the fees are remitted. It is a condition that the exhibition is awarded in competition, the branch or branches of science for which may be fixed by the locality, and that the student pursues his studies satisfactorily.

ECONOMY IN PUDDLING.

AT the present time, perhaps more than ever before in the history of ironmaking, is it necessary that economy should be studied in every branch of iron manufacture, and it would appear that in no way can a greater saving be effected in puddling than by the use of Cambridge's patent fire-bars. These possess many advantages, not the least of which are that they are lighter and cheaper than those now in use, possess greater durability, more economical by the prevention of clinkers, and produce a higher ratio of steam. We are informed that a testimonial, fully bearing out these great qualifications, has been received by the manufacturer, Mr. Alfred Ryland, Birmingham, from Mr. John Evans (Cymro Du), for many years a practical puddler, and over twenty years Puddlers' and Mills manager at Abernant, afterwards at Dowlais, and now at Waterloo Iron Works, West Bromwich. In this he says that these bars "get the heat up better and work more regularly, and will burn cheaper or smaller coal than the old flat bars." And he adds, "I have used these bars with what is called here 'rough slack,' and the iron has come round as soon as in the other furnaces with better coal, which saves a good deal in the price."

* The examination in drawing can, where there is no Art Certificated Teacher, be held by the Science Class Committee, to whom the necessary papers will be sent.

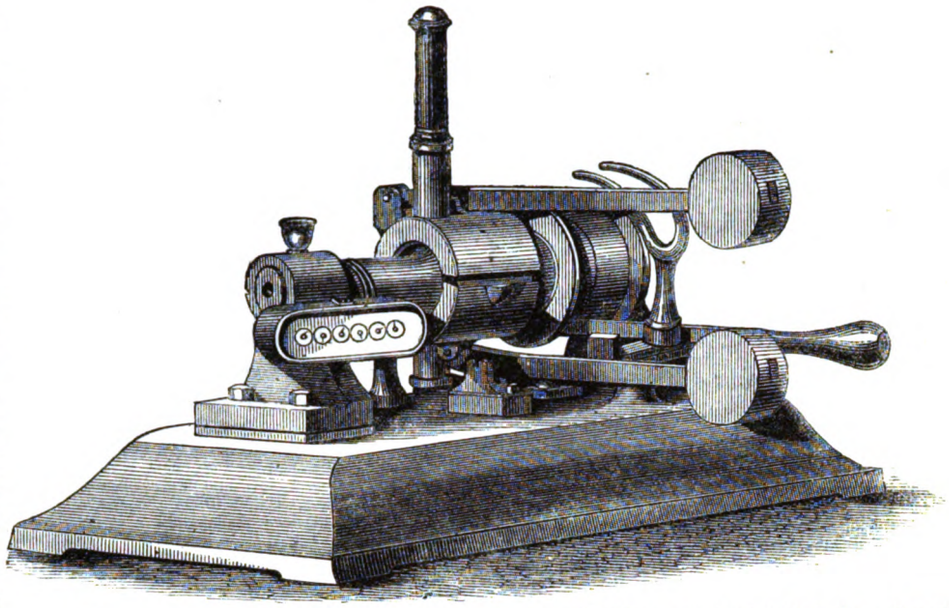
INGRAM AND STAPFER'S PATENT OIL TESTER.

INGRAM AND STAPFER'S PATENT OIL TESTER.



THE testing of lubricants has taxed the ingenuity of many inventors, several machines having been designed for that purpose. Until a recent period the specific gravity alone has been a guide to a knowledge of the lubricating quality of oil, but of late years the nearly interminable varieties of oil that have been introduced causes the hydrometer as a test to be nearly useless. Little toy-like instruments have been used to weigh the friction, all more or less very indefinite in their action. Heat is power, and anything that has a tendency to arrest motion reproduces heat, which we call friction; anything in the shape of a good lubricant prevents heat accumulating and reduces friction. Knowing this, the patentees of the invention under consideration naturally concluded that the oil which allows the greatest number of revolutions to be performed by a shaft with the lowest possible increase of the temperature of the bearings must be a good oil, and save power, which means, in a works, gold. The instrument we illustrate is being rapidly introduced by Messrs. John Bailey and Co., of the Albion Works, Salford, Lancashire, a firm well known for their indicators and testers of various sorts. The illustration, which is from a photograph, shows the instrument very clearly. A bed-plate, two pedestals, fast and loose pulleys, and strap, fork, two brass steps with weighted levers to produce friction, and an indicator to show the revolutions, and a thermometer to indicate the temperature produced, make the thing complete.

The exact money value of oil may be arrived at as follows:—Suppose a certain quantity of No. 1 oil on the machine shows 150deg., by being driven 10,000 revolutions, No. 2 oil shows 150deg., and 7,500 revolutions, or 25 per cent. less value; in addition to this practical way of attaining a result the machine may be driven to a higher temperature to see which oil produces the worst residuum. Of course it will be seen how valuable such an instrument is to consumers of oil, and to oil merchants and refiners, to enable cheap oils to be tested, and various mixtures experimented upon by the machine at various speeds for quick machinery and for heavy bearings. When the instrument is used for the latter oils it should be driven slowly, and the weights placed at the ends of the levers, and for quick machinery *vice versa*.

IMPROVED CALLIPERS.

STRAIGHT-edges, squares, and callipers, have always been the mechanic's companions and assistants in the manipulation of materials. They are his great helps in the construction of mechanical details and erection of works, whether they consist of stone, wood, or iron. Every mechanic knows (or ought to know) that the beauty and efficiency of all artifice increases in proportion as parts approach geometrical accuracy; these hand-tools, therefore, which enable him to make his work straight, parallel, square, or circular, are seldom out of his hands—in fact, they are indispensable adjuncts to the vice, lathe, and plane, and are to be found on almost every work-bench, and in every workman's tool-chest. The straight-edge and square are, of course, only applicable in obtaining plain surfaces and right angles, but callipers are more especially useful in ascertaining the parellelism of surfaces, the diameter and thickness of bodies. There are different sorts, known as outside and inside callipers, or, in other words, callipers which will measure outside and inside diameters. These commonly have their fingers made of flat steel, and when designed for taking outside dimensions are made in a semicircular form, so that the points only shall touch in gauging the work. The inside callipers are made straight, and in shop parlance are known as "leg callipers." The common method in constructing these has been to file the two pieces together, so as to get them exactly alike, and then, after finishing, to rivet them together with a round-headed rivet and washer, to such a degree as to allow opening and closing with a moderate degree of pressure. To get an exact measurement with these, the mechanic has to keep tapping one edge until the points are sufficiently closed to take in the diameter or thickness of the object. There are some objections to this description of callipers, as they spring, and can only be used with any degree of certainty in the hands of an expert mechanic who knows something of the sense of feeling and touch. Spring callipers are now very much used and liked. These are generally made from square steel, and have a screw passing through them, and a thumb-nut for adjusting the points.

The accompanying illustration represents improved callipers, patented by Mr. W. Pond, of Worcester, Mass. It will be observed that they are a combination of the ordinary and spring callipers. Being made of flat steel, and having the screw with a milled head at the side, no springing takes place when gauging a shaft, bolt, pulley, &c. The steel

spring is not part of the callipers, but is put round the joint and held by two pins. Should this spring be broken, the callipers can still be used as the ordinary ones, and a new spring attached at leisure. They are exceedingly neat in form, and are made from the smallest to the largest size. As every mechanic, engineer, and machinist appreciates a reliable and well finished pair of callipers, we have no doubt these so well improved by Mr. Pond will find their way into the hands of numerous workmen and experts. We take these particulars from the "American Journal of Mining."

THE WILSON RIFLE.

MR. WILSON, of Birmingham, has produced a new rifle, upon the bolt principle, for central fire cartridges. We are not at liberty, in consideration of the interests of the inventor, to describe fully at this moment the minutiæ of the breech arrangements; but it will be sufficient to say that lock, hammer, and all outside obstructions are done away with, and that the chamber is opened and closed in two direct motions, that the extractor is simple and trips the empty cartridge-case out of the barrel. The entire mechanism, except the trigger, is situated in and carried by the sliding bolt, which is so constructed that the action of the trigger, and consequently the discharge of the gun, is impossible, unless the bolt is fixed in its proper position. Security from accidental discharge is thus obtained. No other modification of the bolt, or needle-gun system, has approached this weapon for simplicity. The "Standard" states that on the 24th ult. this new rifle was tested at the Woolwich practice ground by the Small Arms Competition Committee in the following manner:—Two targets were made at 500 yards, with 20 shots each, by Private Crofts. The diagram made on the first was 1·92ft.; on the second, 1·32ft. Then for rapidity 20 rounds were fired in 50sec., the quickest firing as yet made with any small-bore or half-inch breech loader. Thirty more shots were personally fired in various ways by the members of the committee themselves. Two further targets of 20 rounds each at 500 yards were then made with the following diagrams:—The one, 1·94ft.; the other, 1·97ft. A strong wind was blowing during the shooting. After this sand was thrown over the closed breech-action trigger, and other parts, for the purpose of trying what effects would be produced by grit and dirt getting into the gun in service. Three rounds were fired under three conditions without any difficulty whatever. The breech arrangement was then opened, and the working parts of the gun internally sanded to make the test more severe. Three shots were again fired from the gun in this state without difficulty. This test was repeated, and the gun fired three times again without difficulty. Three damaged cartridges were then fired, and no injury to the gun occurred.

A further exhibition of the powers of this excellent small-arm took place at the Woolwich range with the most satisfactory results. One hundred and fifty rounds were fired in all. Twenty rounds were fired for accuracy. Direction of range N.N.E., fresh south-west wind blowing. A very good target was made, showing at 500 yards' shooting a mean deviation of 1·41ft. The rifle was fired, as on the previons occasion, by Private Crofts, who discharged, for rapidity, 20 rounds in 45sec., being the most rapid firing produced at the range by any breech-loader of either large or small bore. It was evident at the last trial, when the weapon was put, for the first time, into the serjeant's hands, that four or five seconds might have been saved in rapidity if the shooter had had any previous experience of the gun, and it appears to be pretty generally the opinion that thirty shots per minute could be realized. The mechanism of the arm worked without any impediment, and the gun was raised to the shoulder for each discharge. The arm complete weighs under 8½lb., and the barrel has six rifle grooves, of one turn in 35in. The cartridge used was the latest form made at the Royal Laboratory, with 70 grains of compressed powder, and bullet of 380 grains. The recoil of the gun is very slight. The action of the breech arrangement is, as we have already described, remarkably simple, and altogether the weapon is the most remarkable yet produced on the bolt or Prussian principle. The mechanism is self-locking and self-securing. The act of opening, which is one motion, clears away the old cartridge case, and the pulg or bolt can be detached from the breech in a moment without tools. The mechanism is composed of very few pieces, all of which can be produced by machinery.

THE POLYTECHNIC INSTITUTION.

THE attractions of this popular place of instruction and amusement have just been varied by a judicious change in the programme. The managers have introduced an automaton figure representing Baron Kempelen's well-known automaton chess-player. The figure is placed in the principal hall, immediately under the figure of Leotard (who still goes through his sensational performances twice a day), and can therefore be well seen from all parts. The figure, on being wound up, plays a game of chess with a little boy, with much apparent intelligence, and with sufficient ability to beat his competitor. The figure afterwards hands to the little fellow with whom it has been playing all the pieces on the board, and performs the difficult feat of placing a knight on every one of the squares without diverging from the mode of movement laid down for it. Professor Pepper continues to interest his audiences with Faraday's beautiful discoveries. He also discourses on spiritual manifestations, pointing out the extensive imposture that has been practised on the public in the name of mesmerism and spiritualism. The professor illustrates his lecture with some startling illusions, such as the floating of stout ladies, heavy tables, and hats, in the air. Mr. Thomas Tobin—Professor Pepper's able coadjutor—gives entertaining and instructive sermons in stones, in the course of which he exemplifies, by means of some exquisitely got-up illustrations of England's cathedrals, abbeys, and ancient buildings generally, the progress this country has made in architecture. A well-timed and beautifully illustrated lecture by Mr. Thomas Baines, F.R.G.S., on Abyssinia and the Abyssinian Expedition, forms another prominent feature of the Polytechnic entertainment, which is well worthy of the patronage and support it continues to receive.

UTILIZATION OF SLAG, &c.

THE utilization of waste slag is a question which has had a large share of attention given to it. The last proposition with which we are acquainted is that of Mr. J. Hargreaves, of Appleton-within-Widnes, who has patented some improvements in this direction. The objects of the invention are twofold. They are, firstly, to utilize that waste material or product which rises to the surface of molten iron during its conversion into steel or soft iron when salts which yield oxygen on the application of heat are the agents employed, and which he terms steel slag; and, secondly, to utilize another waste material or product, called by him steel cinder, obtained during the manufacture of steel and soft iron when steel slag is used. The steel slag consists principally of carbonate, silicate, phosphate, sulphate, sulphite, sulphide, chloride, cyanide, and ferrocyanide of sodium or potassium, together with oxide of iron and oxide of manganese, and when chromate of soda or potassa are the oxidizing salts used in the manufacture of steel and soft iron from cast iron, there is also oxide of chromium present. The steel cinder has a similar composition, except that it contains more silica, oxide of iron, and oxide of manganese, sulphur, phosphorus, and their acids.

Mr. Hargreaves utilizes the said waste product as follows:—First, in the manufacture of glass, by the addition of and fusion with silica, lime, and oxides of lead and zinc or other substances tending to render the glass insoluble in water and unaffected by atmospheric influences; and, secondly, by dissolving the soluble portions of the steel slag or steel cinder by lixiviation or boiling in water. The insoluble impurities in suspension are allowed to settle to the bottom, the clear solution is then drained off, concentrated to dryness, and roasted, adding nitrate of soda, nitrate of potassa, or other oxidizing salt to oxidize any sulphide of sodium or sulphide of potassium that may be present. The material thus produced is used as a detergent in washing, and also for other purposes to which alkalies are applied.

Mr. Hargreaves also obtains carbonate of soda and carbonate or potassa or bicarbonate of soda or bicarbonate of potassa by passing carbonic acid through the solution obtained from steel slag and steel cinder, as mentioned under the second head of the invention. Or he adds bicarbonate of soda or bicarbonate of potassa to the solution to precipitate the silica and other impurities present. He then concentrates to dryness and roasts the material, and if the steel slag or steel cinder was produced when a salt of soda was used Mr. Hargreaves obtains crystals of soda, or makes bicarbonate of soda in the ordinary manner, or he concentrates to dryness and obtains soda ash. If a salt of potassa was used in producing the steel slag or steel cinder, the inventor obtains the ordinary potash or pearl-ash of commerce, or he still further exposes the potash or pearlash to the action of carbonic acid and obtains bicarbonate of potassa.

In the fourth place, the inventor obtains caustic soda or caustic potassa by boiling a solution of specific gravity 1100 or 1090 obtained from steel slag and steel cinder, with caustic or quicklime, and adding nitrate of soda or nitrate of potassa, or other oxidizing salt, to the solution to oxidize any sulphide of sodium or sulphide of potassium that may be present in the caustic solution. Or he oxidizes the sulphides by the jet processes invented by him in 1864, and now in common use for oxidizing crude soda liquors, and then concentrates by boiling until it will solidify on cooling, or he uses the caustic solution in the manufacture of soap, paper, and other materials without concentration.

Mr. Hargreaves has further ascertained that by passing the steel slag or steel cinder through incandescent carbon in the form of charcoal or coke he obtains the steel slag more free from oxide of manganese or oxide of iron, and the oxide of iron and oxide of manganese are reduced to the metallic state, and the salts of soda or potassa contained therein are rendered much more soluble. Therefore, when making carbonate of soda or potassa, or when making caustic soda or potassa, Mr. Hargreaves prefers to melt the steel slag or steel cinder in a blast furnace, or to fuse them in a reverberatory furnace together with coal or other carbonaceous matter, and then treat, as described, for the formation of carbonates and hydrates of soda or potassa.

THE INSTITUTION OF CIVIL ENGINEERS.

AT the meeting of this Society on Tuesday evening, the 3rd instant, Mr. Charles Hutton Gregory, President, in the chair, sixteen candidates were balloted for, and duly elected, including, as members, Mr. William Douglass, Trinity Works, Penzance; Lieutenant Colonel John Pitt Kennedy, Consulting Engineer to the Bombay, Baroda, and Central India Railway Company; Mr. Richard Laybourne, late Locomotive Superintendent of the Monmouthshire Railway; Mr. William Henry Edward Napier, late a Resident Engineer on the Berlin-Gorlitzer and East Prussian Railways; and Mr. Josiah Timmis Smith, Engineer of the Hæmatite Steel and Iron Works, Barrow-in-Furness; and as Associates, Mr. James Binfield Bird, Cowes; Mr. William Gammon, Lambeth; Mr. Thomas Bland Garland, Valparaiso; Mr. William Hunt, Westminster; Mr. James Trubshaw Johnson, Lichfield; Lieutenant Colonel William Lawtie Morrison, R.E., Surveyor-General of the Mauritius; Mr. Patrick Ogilvie, Hambledon; Mr. Robert Sabine, Westminster; Mr. James Shaw, Leadenhall-street; Mr. Samuel Swarbrick, General Manager of the Great Eastern Railway Company; and Mr. Albert Vickers, Inverness-terrace. It was also announced that the Council, acting under the provisions of Section IV. of the bye-laws, had since the last announcement admitted as Students of the Institution, Benjamin Hall Blyth, M.A., Alfred George Brookes, Richard Ernest Brounger, William Augustus Kennedy Gostling, Arthur Henry Heath, Charles Assheton Whately Pownall, Percy Frederic Tarbutt, and Frederick Toplis.

MANUFACTURE OF OAKUM.

THE object of the invention we are about to describe is to prepare oakum from untarred or insufficiently tarred fibre, such as tow obtained from white or other ropes, or the shorts from dressing hemp or fibres derived from other sources, by impregnating it with a solution of tar dissolved in a suitable solvent, the latter being more easily evaporated than the tar, and then driving off and again collecting the volatile solvent if desired. It is the patented invention of Mr. J. E. Hodgkin, of Liverpool, and the solvent which he has found most advantageous for this purpose has been benzole. Other light oils of coal tar or the light oils derived from petroleum, bi-sulphide of carbon, or wood naphtha, however, may be employed. The simplest mode of applying the tar in solution is to steep the fibre in a mixture made by dissolving tar either cold or at a higher temperature in any of the above-named solvents, and then placing it in a close vessel and driving off the vapour of the solvent into a still so as to collect it for future use.

The apparatus employed for this purpose is the following:—In order to prepare the solution of tar for impregnating tow or other fibre, the tar and solvent (in such proportions that when dissolved the solution will be sufficiently fluid as to readily saturate or impregnate the tow or other vegetable fibres introduced into it with the desired amount of tar) are introduced into a mixing vessel which may be heated if desired. A shaft furnished with knives or beaters passes through the mixing vessel, and is supported in exterior bearings. The mixing vessel can either be made to revolve rapidly, the shafts and knives being stationary, or vice versa, the object being thoroughly to dissolve the tar without waste of the solvent by evaporation. When thoroughly mixed the solution is allowed to flow into another vessel in which by filtration (under pressure or by settling), the small insoluble portion of the tar (if any) is separated from the clear liquor. The tow or other fibre is placed in a steam jacketed chamber, the man-hole joint being then made tight; this chamber is then filled with the tar liquor, steam being admitted into the jacket in order to heat the tow and liquor, and thus thoroughly impregnate the tow. A piston may be arranged in the vessel and be caused to descend so as to squeeze the liquor out of the tow into a space arranged under a grating or false bottom in the inner impregnating chamber. The draining of the tar liquor from the tow or fibre in the impregnating vessel is usually all that is required unless it is desired to facilitate the process by pressure. When the tow is sufficiently free from the tar liquor the steam is turned off and the superfluous liquor is allowed to flow into a receiver. Hot air or steam is then admitted again to the jacket around the impregnating chamber, by which means the solvent with the tar in solution is driven off into a still, and there condensed by cold water or recovered in any other manner.

The tow is now evenly saturated with tar and contains an inappreciable quantity of the solvent; it is then removed from the impregnating chamber which is cooled ready for receiving the next batch of fibre. A few hours' exposure to a current of warm air renders the oakum fit for market, and it can then be finally carded. The superfluous tar liquor is discharged from the impregnating vessel into a suitable receiver or closed vessel connected by a pipe with an air condensing or force pump, and from the bottom of the closed vessel or receiver a pipe rises to the mixing vessel, so that by the application of pressure to the closed vessel or receiver by the action of the pump, the liquor is driven up into the mixing vessel again. The distilled solvent from the still also runs into the same mixing vessel by gravitation, and all that is required to prepare the apparatus for the next operation is to add as much tar as the previous batch of tow has taken up together with any slight loss of solvent which may have taken place. Warm air may be forced or drawn through the impregnated fibre after its saturation by any suitable means, the air being arranged to pass over with the vapour into the still, in which case the use of the steam jacket may be dispensed with in this part of the process.

Obituary.

WE announce with regret the death of Mr. Michael Lane, engineer-in-chief to the Great Western Railway Company, which occurred on the 27th ult., after a short illness. The deceased gentleman was engaged on the works of the Thames Tunnel in 1825, which was the commencement of a career of usefulness and honour. A few years later he became the resident engineer of the Bristol Docks, under Mr. Brunel. He was afterwards engaged on the Monkwearmouth Dock, Sunderland (north shore), the works of which he carried out. In 1840, Mr. Lane commenced his duties on the Great Western Railway, being engaged on the western division of that line. He was afterwards appointed resident engineer of the Hull Docks, but, in 1845, he rejoined the Great Western Company as superintendent of permanent way. At the close of 1860 Mr. Lane was made engineer-in-chief to the company, which office he retained up to the time of his death. Mr. Lane was a thoroughly practical man, and was greatly esteemed for his integrity and kindly disposition, which drew around him a large circle of friends and acquaintances who sincerely regret his loss. His funeral took place on Wednesday last, and his remains were followed to Kensal-green by a large number of the officers and staff of the Great Western Company, by whom he was highly respected.

WE regret also to announce the death of Mr. Stewart, the chairman of the Anglo-American Telegraph Company. He was taken ill while attending to business in the City on Wednesday week, and expired before he could be removed to his residence. Mr. Stewart held for many years the responsible position of secretary to the London and North-Western Railway.

MR. JOHN HERAPATH, the cousin of Mr. William Herapath, the celebrated chemist of Bristol, whose death we lately recorded, died on Tuesday week, at his residence, Catford Bridge, Kent. Mr. Herapath was engaged in completing his concluding volume of "Mathematical Physics" for publication when he caught a cold which, though it at first appeared to be slight, terminated in his death.

Correspondence.

SQUARING THE CIRCLE.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—Geometrical discussion should not be acrimonious, and I therefore only reply to your correspondent "A. W.," writing you on 17th current, that I wished to say no more of his letter of 13th January, in my rejoinder to it of 7th current, than to show from his calculations, and those of P. H. Van der Weyde, compared, how wide of

Digitized by Google

truth the present method of calculating the area of a circle and the ratio of its diameter to its circumference leads its votaries. I hope it will satisfy him if I now say that the remainder of his letter, which I did not notice, was, as all such approximations must ever be, equally erroneous with that which I did.

I regret that your correspondent "Commander, R. N.," under date 23rd current, in your issue of today, has avoided the question put to him in mine of 14th current, by a reference to the preface of the "Nautical Almanack." That publication having been my companion over about 380,000 miles of the salt sea, I am not ignorant of its construction. But having proved the exact ratio of the diameter of a circle to its circumference to be 5 to 16, I wished to show that the ordinary value of 1 to 3.14159, &c., and its results can never be anything more than approximations wide of the exact truth, as are also the laws of Kepler, to the elucidation of which, in the "Nautical Almanack," they are applied. These laws are simply generalized theories, deduced by their author from the close life-long telescopic observations of Tycho Brahe and his predecessors. The most advanced astronomic minds are at present inquiring not only into the conclusiveness of some of Kepler's theories, but also into the truth of the philosophy of some of Sir Isaac Newton's generalizations on the subject of gravity, in the investigations of which the sublime theoretically approximative doctrines of Kepler so greatly aided him. To explain my meaning, I may be pardoned perhaps the following quotation from the eighth edition of the Encyc. Brit. Art. Ast., Vol. IV., page 61. "If the planets had no mutual attraction, and obeyed only the central force of the sun, the problem of determining the different circumstances of their motion would be one of easy solution, and each of them would accurately describe an ellipse on the plane of its orbit, according to the laws of Kepler. In consequence, however, of their mutual attraction, every planet is compelled to deviate more or less from its ellipse, so that when the matter is viewed with mathematical precision, the laws of Kepler belong only to an ideal system, and have no actual existence in nature." These and similar following passages show how unapt an argument against the correctness of my discoveries on the square of the circle and its proportional diametrical and circumferential values is the "Nautical Almanack." The fact is, that the sheet anchor in the construction of that periodical is actual telescopic observation recorded with precision by the astronomical clock and its accompanying electric chronograph.

For his own sake, I will only at present notice the letter of your correspondent, Mr William Hayden, of 22nd February, so far as to ask him whether he admits that the diagram in my letter of 7th current, shows that the four spandrils and the central square are together equal to two central squares of the value of F G H I, diagram No. 7, in my letter of 11th October last. In doing this, I would remind him that geometry is a science, not of appearance or of approximation, but of hard fact and indisputable truth.—I am, Sir, yours, &c.,

London, February 28. WILLIAM HARVEY.

Letter V.

Sir,—To Mr. Hayden I have to acknowledge an error in correcting the rule given by him for finding the circumference of a circle. I should have said, that half the difference between three diameters and the depth of a segment of a fourth of the circle, and three diameters and twice the depth of the segment of which the radius is the chord, added to his own rule, would give the true circumference.

Mr. Scutt is correct in saying that the rule given by me for finding the area of the circle is not new. I find it is a corollary from the calculations of Professor James Gregory, of Edinburgh, published in Padua in 1668, of polygons within and without the circle, which he carried up as high as 32,768 sides, at which point the polygons within and without became equal (of course impossible) to each other, and which he fixed upon as the approximative area and circumference of the circle, and to whom we owe our present representative decimals. Although the rule is the same, I claim in behalf of my own constructive problem that it embraces the area by a simpler, direct, and more conclusive proof, free from the taint of approximation, and is by so much a step in advance.

I thank "A. W." for his notice and calculation upon my constructive proof of the circumference (letter 4). I have reconsidered it, and reconstructed it upon a larger scale. It gives me 13 dia. 41 circumference, which is between 7-22 and 6-19ths, and in my objection to decimals and the decimal system altogether, I feel that I can only bow to a delicate mechanical manipulation, with fractional or angular expressions as final. When "Commander, R. N." insists upon the exact truth of the digital verbiage of decimals to be proved by "the fact that the computed positions of the celestial bodies agree exactly with their observed positions," does he reflect on the impossible pelicacy required of the observer? It is not the case of "there or thereabouts" to the tenth of a second or so, but something infinitely finer. In the first place, the chronometer must have corresponding divisions with the decimals; next, what mortal will we find endowed with perceptions so fine as to be able to decide the climax of those flying myriads? And what rate must muscular motion be, to reply to that mental decision, and fix it upon the yet unconstructed clock? Decimals are delusive, and chiefly remarkable for their own condemnation, by showing the enormous number of positions not divisible by ten, but which they persist in so dividing—the lading of water with a sieve—and the mis le failure they exhibit when applied to coins, weights, and measures. Great honour will be due to the mathematical St. George who shall arise and slay this decimal dragon, and release the natural system so long in chains, and which promises to be altogether devoured if he come not soon, by the percolation of French ideas amongst ourselves and other nations.—I am, Sir, yours, &c.,

March 2. JOSEPH A. NICHOLSON.

Sir,—In his letter of February 7, Mr. Harvey says "so as to form with a quarter of the central square 5 6 7"; but as it is not at all obvious that the three curved spaces 5 6 7 are a quarter of the central square, I must ask him for the proof thereof.—I am, Sir, yours, &c., THOS. C. HAINES.

Belfast, March 2.

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith.—ED. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

RECEIVED.—T. C.—S. B.—Messrs. C. M. and Co.—G. W. H.—H. C.—W. T. C.—G. G. P.—C. F.—R. B.—G. E. P.—W. H.—G. A. W.—J. H. P.—J. A. N.—F. W. P.—Messrs. J. B. and Co.—A. C. B.—R. I.—T. C. H.—J. N.—W. H. Meetings for the Week.

MON.—Royal Institution of Naval Architects.—Ordinary General Meeting. A communication from the President on "The Antiquities of Frejus, in the South of France;" and Mr. H. W. Brewer on "The Mediæval Architecture of Central and Southern Germany," at 8 p.m.

TUES.—Royal Institution.—Mr. George Scharf on "Historical Portraiture," at 3 p.m.

The Institution of Civil Engineers.—Discussion upon Mr. Sandberg's paper on "The Manufacture and Wear of Rails," at 8 p.m.

THURS. — Royal Institution.—Mr. George Scharf, on "Historical Portraiture," at 3 p.m.

FRI.—Royal Institution.—Mr. Stanley Jevons, on "The Exhaustion of our Coal Mines," at 8 p.m.

Royal United Service Institution.—Lieut.-Colonel C. H. Owen, R.A., Professor of Artillery, Royal Military Academy, Woolwich, on "Modern Artillery as Exhibited in Paris in 1867," at 3 p.m.

SAT.—Royal Institution.—Professor Roscoe on "The Non-Metallic Elements," at 3 p.m.

London Association of Foremen Engineers.—Mr. David Walker on "The Shrinkage of Cast Iron," at 8 p.m.

Naval, Military, and Gunnery Items.

WE are glad to hear that the ceremony of "drumming out" is, in future, to be dispensed with in the army, for it always seemed to us to savour more of honour than of dishonour.

FROM a return lately published, it appears that the sums included in the army estimates for 1868-69, on account of the military expenditure in the colonies, amount to £3,388,023. The total colonial contributions to be paid into the exchequer during the ensuing year amount to only £365,760.

IT is stated that the Papal Government have adopted the Remington breech-loader, and they have given out an order to the extent of 10,000; 5,000 of them are being made in Birmingham, and 5,000 in Belgium. All the barrels are to be made on Deakin and Johnson's punched steel process.

THE officer in command of the ram "Stonewall," now on her way to Japan for the navy of that country, writes that he arrived at Callao, January 23, and expected soon to sail for Honolulu. The ram successfully rounded Cape Horn, and it was hoped would be as successful in crossing the Pacific.

THERE appears to be some idea of reorganizing the Austrian naval forces in the Adriatic. Following the example of France and England, the Government of Vienna is said to intend to form an experimental squadron composed of five frigates (three of them iron-clad), two steam corvettes, and three gunboats. One division of this force would remain in the Levant, while the two others would perform evolutions at sea for the exercise and instruction of the crews.

THE Army Estimates for 1868-69 provide for the following as the number of the regular army:—British establishment, including depots in the United Kingdom of regiments in India, 6,894 officers, 13,091 non-commissioned officers, 116,665 rank and file; total, 136,650, being 595 fewer than in 1867. The establishment of Her Majesty's British forces in India to be paid out of Indian revenues is 3,592 officers, 5,318 non-commissioned officers, and 55,556 rank and file; total, 64,466, being 826 fewer than in 1867.

In order to expedite the work of fitting the "Hercules," at Chatham, a bridge of boats is about being constructed from the dockyard to that part of the harbour where the "Hercules" is lying, in order to facilitate the workmen proceeding to and from the vessel, and transporting the materials required in her fitment from the dockyard. The intended bridge will be constructed with the iron mortar boats laid up high and dry at Chatham dockyard ever since the close of the Russian war. Notices have been issued that the channel between the dockyard and that part of the harbour where the "Hercules" is lying will be closed to the passage of vessels of all kinds until further notice.

MESSRS. R. NAPIER AND SONS have launched a twin-screw "Monitor," built by them for the Dutch Government, and of 1,600 tons burden, builder's measurement. The dimensions of this "Monitor" are as follows:—Length over all, 187ft.; breadth 44ft.; depth, 11ft. 6in. The armour-plating on the sides of the vessel is 5½in. thick, with 10-in. teak backing, and an iron inner skin 1in. thick, supported by strong iron frames. The turret is on Captain Cole's system, plated with 8in. of armour, with 12-in. teak backing on a 1-in. inner skin. The vessel, which has been named the "De Tyger," is to be armed with two 300-pounder 12½-ton Armstrong guns. The engines, which are also made by Messrs. Napier, are of 140-horse power, nominal.

IN the Annual Musketry Returns for 1867-8, it is stated:—The Field-Marshal Commanding-in-Chief observes with satisfaction a marked improvement in the shooting of the troops, notwithstanding the reduction in the amount of preliminary instruction sanctioned by the existing musketry regulations, and, while fully disposed to give the new breech-loading arms all the credit to which they are entitled, he feels it due to commanding officers and others charged with the training of the men, to place on record his conviction that the gratifying progress which has been made this year is in no small degree attributable to the increased attention which has been bestowed on the instruction of the troops. The general results of the shooting of the several infantry battalions during the past and previous years will be found contrasted in the following table:—

Number of Battalions whose Shooting is							
Year	Very Good		Good		Moderate		Total.
1866-67	... 13	...	30	...	34	...	79
1867-68	... 40	...	25	...	10	...	75

And, although the practices from which "the figure of merit" is compiled is most satisfactory, his Royal Highness is compelled again to advert to the fact that the independent firing is frequently very indifferent, which he can only attribute to undue importance being attached to mere rapidity of fire, and to a want of attention to deliberate aim being taken by each soldier during the practice.

Miscellanea.

THE iron portion of the Exhibition building in the Champs Elysees has been sold to a company of contractors for the sum of £60,000; it is not yet known what is to be its future destination.

THE number of visitors at the Patent Office, South Kensington, for the week ending February 29, was 3,018; total number since the opening of the museum, free daily (May 12, 1858), 1,253,598.

THE "Lewiston (Maine) Journal" states that a gentleman residing at Auburn has this winter made use of his large hothouses for the culture of what genteel young ladies in the country call "hen fruit."

THE Right Hon. H. T. L. Corrie, M.P., First Lord of the Admiralty, has kindly consented to preside at the annual meeting of the National Lifeboat Institution, which is to be held on Tuesday, the 10th inst., at the London Tavern, Bishopsgate-street.

AN exhibition of the works of living artists, Dutch and foreign, is announced to open on September 7, in the present year, at Amsterdam, and to close on October 5, unless the directors see reason for extension of the time.

Digitized by Google

AT the monthly meeting of the London Association of Foremen Engineers, to be held at the George Hotel, Aldermanbury, on Saturday next, the 7th inst., Mr. David Walker will read a paper on "The Shrinkage of Cast Iron." The sitting opens at 8 p.m.

IT may be convenient to persons who have to send old letters for literary purposes to be informed that they may be sent by post under the usual conditions of book postage, at 1d. for 4oz., and need not be sent as letters at 1d. for half an ounce.

THE number of visitors at the South Kensington Museum during the week ending February 29, were:—On Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 9,003; Wednesday, Thursday, and Friday (admission, 6d.), from 10 a.m. till 4 p.m., 1,436—total, 10,439. Average of corresponding week in former years, 10,615. Total from the opening of the museum, 7,220,028.

THE "Niagara Falls Gazette" says that workmen are engaged in putting cables over the river for the new suspension-bridge at that place. The ice bridge, instead of being a formidable rival, is a most valuable aid in this work. The first wire cable was thrown across from the Canada side on Monday. It is a 2-inch wire rope, and is intended as the pioneer of the large cable, which will be thrown over the chasm when milder weather comes.

THE Société Agricole of Brabant announces a great exhibition of cattle and implements, to take place in Brussels in the middle of the month of June next. The mechanical portion of the exhibition is to be universal. By a royal decree there is to be a lottery established for the purchase of implements, which are to be distributed by lot amongst the subscribers. This is, we believe, the first time that a lottery has been established in the interest of agriculture.

MR. E. HOLLAND, M.P., of Dumbleton-hall, was lately summoned for allowing a locomotive engine of his to travel on the turnpike road between Ashchurch and Evesham without the owner's name and residence being painted thereon. Mr. Winterbotham, who appeared for Mr. Holland, admitted the offence, and expressed regret that he should have infringed his own Act of Parliament. The hon. member was fined 2s. 6d., and 11s. expenses. The incident created much merriment in court.

AT the seventh meeting of the present session of the Royal Geographical Society, Sir R. I. Murchison, Bart., president, in the chair, the following new Fellows were elected:—Captain Edward Baynton, N. Cork, W. R. Dalziel, A. Gillett, D. Haysman, Henry Kingsley, R. L. Middleton Kitto, J. W. Miers, M. L. Mavrogordato, J. E. C. Pryce, Hon. Edward Stirling, and J. W. S. Wyllie. A paper was read on the Geographical Results of the Abyssinian Expedition, to January 22, 1868, by Clements R. Markham.

AT last week's sitting of the Academy of Sciences, M. Le Verrier, in a letter, gave some further information about the 96th telescopic planet discovered at Marseilles on the 17th ult., stating that on the 20th it had been observed at Paris by M. Loewy with the great meridian instrument. M. Delaunay, after M. Le Verrier's letter had been read, expressed his regret that he (M. Le Verrier) should persist in refusing to mention the names of the observers who discovered small planets at the Observatory of Marseilles, and informed the Academy that the young observer who had discovered the 96th planet was M. Borelly.

AT the general monthly meeting of the Royal Institution of Great Britain, held on Monday, March 2, 1868, Sir Henry Holland, Bart., president, in the chair, F. D. Banister, Esq.; P. H. Berthon, Esq. Miss Martha Conway; Mrs. Ernest Hankey; Charles Hart, Esq.; Mrs. Henry Huth; Benjamin Isaac, Esq.; Morton Latham, Esq.; Mrs. Le Breton; Robert Longsdon, Esq.; Alexander Macmillan, Esq.; W. I. Marter, Esq.; Thomas Parry, Esq., M.P.; Mrs. Frederick Pollock; Robert Prance, Esq; Miss Edith Prance; Edward Smirke, Esq.; J. P. Stocker, Esq.; C. H. L. Woodd, Esq., were elected members of the Royal Institution.

AT the last meeting of the Royal Horticultural Society, the exhibition exceeded in the quantity and beauty of subjects any hitherto recorded. Orchids supplied the most attractive articles. The varieties of Cattleya were most lovely, but far the finest Orchid was Oncidium macranthum, it is believed from New Granada, which came from the collection of Lord Londesborough. Mr. W. Wilson Saunders, F.R.S., presided, before an unusally large attendance of the fellows, and the following candidates were elected new fellows, viz.:—Mr. W. Adams, Mrs. Brown, Mrs. Forbes, Lieut. General Hay, Mrs. Jones, Mrs. Loveland, Dr. H. R. Madden, Geo. Thomas Selby, &c.

IT appears that at the close of 1867 four miles and 5,035ft. of the Mont Cenis Tunnel had been completed, leaving two miles and 4,018ft. still to be pierced. The distance pierced in 1867 was 5,040ft., as compared with 3,416ft. in 1866, 4,079ft. in 1865, 3,626ft. in 1864, 2,673ft. in 1863, 2,076ft. in 1862, 1,210ft. in 1861, 1,144ft. in 1860, and 2,889ft. in the preceding years. The outlay made upon this remarkable and important work (which has now been more than ten years on hand) amounted at the close of 1867 to about £1,700,000. It is now hoped that the tunnel will be completed in 1871. Its length when finished will be seven miles 3,773ft., and its total cost will be about £2,500,000, or something more than £300,000 per mile.

THE "Nord" gives a curious calculation as to the proportion in which rewards were distributed to the exhibitors of France. England, Belgium, Austria and Russia, at the Universal Exhibition. France had 15,025 exhibitors, of whom 9,122 were distinguished either by medals, or honourably mentioned—that is 60 per cent.; Great Britain, 6,176 exhibitors, 1,026 received rewards—proportion, 26 per cent.; Austria, 2,094 exhibitors, 916 nominated, &c—43 per cent.; Prussia, 2,249 exhibitors, 485 nominated—21 per cent.; and Belgium, 50,226 exhibitors, 18,840 of whom received recompenses—that is, 37 per cent. on the whole. Therefore Belgium, for the merit of her industrial productions, took the second place of honour.

THE average number of houses supplied last year by each of the London water companies, and the average daily supply of water in gallons, respectively, was as follow:—Chelsea, 26,875 and 8,087,258; West Middlesex, 36,881 and 8,816,486; Southwark and Vauxhall, 71,558 and 13,629,758; Grand Junction, 27,190 and 9,533,432; Lambeth, 38,320 and 8,975,533; New River, 113,462 and 23,790,667; East London, 92,652 and 19,298,241; Kent, 34,504 and 6,468,873. Thus, from the Thames, 200,824 houses were supplied with 49,042,467 gallons daily; and from the Lea and other sources 240,618 houses were supplied with 49,557,781 gallons daily. In the aggregate, the London companies supplied 441,442 houses with 98,600,248 gallons of water on an average daily. The quantity used for domestic purposes, or for house supply, was about 81,033,800 gallons, or 26·3 gallons per head of population.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgement:—

BOILERS AND FURNACES—2235, 2264, 2266
BUILDINGS AND BUILDING MATERIALS—None.
CHEMISTRY AND PHOTOGRAPHY—2239, 2259
CULTIVATION OF THE SOIL, including agricultural implements and machines—2191, 2210, 2251, 2260
ELECTRICAL APPARATUS—2192, 2221, 2241
FIBROUS FABRICS, including machinery for treating fibre, pulp, paper, &c.—2201, 2202, 2208, 2209, 2211, 2214, 2219, 2242, 2243, 2244
FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—2213, 2237, 2238, 2250
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c.—None.
GENERAL MACHINERY—2218, 2229, 2233, 2236, 2246, 2253, 2255, 2261
LIGHTING, HEATING, AND VENTILATING—2188, 2194, 2196, 2199
METALS, including apparatus for their manufacture—2189
MISCELLANEOUS—2193, 2212, 2215, 2220, 2224, 2225, 2226, 2230, 2231, 2232, 2240, 2247, 2248, 2252, 2256, 2257, 2265, 2267
ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—2207, 2217, 2234, 2262
SHIPS AND BOATS, including their fittings—2204, 2205, 2223, 2254
STEAM ENGINES—2245, 2249
WARFARE—2190, 2216, 2227, 2228, 2263

2186 E. RAVENSCROFT. *Improvements in lamps.* Dated July 27, 1867.

This invention relates to lamps in which flat wicks are principally employed, and consists of the arrangement of the wicks, wick holders, and burners of the said lamps. In arranging the wicks, wick holders, and burners of lamps, according to this invention the patentee employs by preference three of the flat wicks, wick holders, and burners, and arranges them radially, so that the plane of each wick, wick holder, and burner forms an angle of 120deg. with the wick, wick holder, and burner on either side of it. The burners may open into each other, or they may communicate separately with the reservoir. By arranging the wicks, wick holders, and burners in the manner described, an equal illumination is obtained on all sides of the lamp, which is not the case with lamps having one flat wick, wick holder, and burner. The invention is especially applicable to lamps for railway carriages, but also to lamps of other kinds.—Patent completed.

2188 W. L. L. LEAVER and A. SMALLEY. *An improved method of lighting house and other fires.* Dated July 29, 1867.

First, the inventors fix on or apply to some convenient part of the gas tubes in the house, building, or office (as may be required), one end of an elastic flexible tube made of any material found most suitable, and terminating at the other end in a metal extremity, which extremity is made with one or more gas jets or burners. Second, this part of the invention containing the gas jets or burners is then put in the place where the fire is required to be lighted or kindled, the gas being ignited in the jets or burners, and the coal or combustible being placed so that the flame from the said jets or burners may come in contact with it till the fuel is sufficiently ignited, when the apparatus may be removed.—Patent abandoned.

2189 T. GREENER and W. ELLIS. *Improvements in the manufacture of iron, and in the production of felting for improving the quality and yield of iron in the process of reduction.* Dated July 29, 1867.

The patentees claim, first, the use for the bottoms of heating or mill furnaces of ores or substances containing oxide of iron, or the equivalents of such substances, in the manner descrit ed. Second, the method described of securing the cinder obtained from the iron in the heating furnace by a dry bottom, and the use of such cinder for "felting" for puddling furnaces, alone or combined with other substances, as described.—Patent completed.

2190 A. M. CLARK. *Improvements in projectiles.* (A communication.) Dated July 29, 1867.

This invention relates to the application of a pasteboard plug which is moulded in the required form before its introduction into the projectile. The pasteboard, being strongly compressed in all ways, will not be acted on by the gases, and will retain its original form even after the ball has reached its destination.—Patent completed.

2191 W. R. LAKE. *Improvements in machinery for hulling rice and other grains.* (A communication.) Dated July 29, 1867.

This invention relates to mechanism for hulling rice and other grains or seeds, and consists in combining with a stationary grooved or ribbed plate or plates an endless movable apron made up of a series of ribbed or corrugated plates. The invention is not described without reference to the drawings.—Patent completed.

2192 G. DAVIES. *Improvements in insulators for telegraphic wires.* (A communication.) Dated July 29, 1867.

The patentees claim, first, the use of paraffin as an insulating medium in the construction of telegraphic insulators by immersing the parts therein whilst in a heated state, substantially set forth. Second, the use of blown glass as an insulating medium in the construction of such insulators. Third, the improved construction of telegraphic insulator particularly described. Fourth, placing the points of the arms or prongs of the wire holder of telegraphic insulators nearer to the lower edge of the metallic outer casing or shell than any other part of the holder is to any other part of the said casing or shield, for the purpose of preventing the deleterious effects of lighting thereupon, substantially as described.—Patent completed.

2193 P. G. B. WESTMACOTT. *Improvements in cranes and apparatus for raising, hauling, and lowering weights.* Dated July 29, 1867.

The patentee employs a chain pinion or drum which receives motion when required by means of the auxiliary power; it may be by gearing, or connecting it with a wheel round which an endless hand chain passes, or in other ways the chain pinion or drum may be drawn by the auxiliary power. The hoisting chain of the crane is arranged to pass alongside of the chain pinion or drum, and when the auxiliary power is to be employed, it is deflected from its direct course by a movable guide pulley, mounted on a hand lever, so as to cause the chain to bear against the chain pinion or drum, and to gear with it, the links of the chain being held by suitable recesses and projections on the face of the pinion or drum. When the auxiliary power is not required, by shifting the guide pulley the chain is allowed to pass clear of the pinion or drum.—Patent completed.

2194 D. HODGE and R. C. WITTY. *Improvements in apparatus to be used in making gas from petroleum and other liquids.* Dated July 29, 1867.

Here the patentees employ a cylindrical retort of cast iron filled with fragments of firebrick, &c. The retort is set in a furnace, so that it may be heated uniformly all over. Near one end of the retort is a nozzle through which the petroleum is introduced from a cistern above; the quantity admitted is regulated by the means hereinafter described. The petroleum or liquid passing in amongst the heated firebrick in the retort becomes converted into permanent gas, which is led off at the other end of the retort into a washing vessel, which is a cistern closed at the top, and having in it partitions dipping down into water. The gas entering at one end of the washing vessel has to force itself down under these partitions, and through the water, to get to the other end of the washing vessel, whence it is led away, and in this manner any petroleum which escapes conversion into gas is separated and re-collected. From the washing vessel the gas is conducted into a small gasometer, into which, also, the gas service pipe opens. On the top of the gasometer a small wheel bears, the axis of which is in connection with a lever on the plug of a stop-cock which regulates the flow of petroleum or liquid to the retort, so that, as the gasometer fills and rises, it moves this lever, and with it the plug of the stop-cock, and so diminishes and gradually shuts off the supply of liquid.—Patent completed.

2195 J. H. WYATT. *Improvements in the construction of studs, buttons, solitaire studs, and the like.* Dated July 29, 1867.

This invention consists in the construction of studs, buttons, solitaire studs, and the like, so that they are capable of carrying or confining as many or as few folds of linen, or other material, as the wearer may desire. The invention, as applied to a collar stud, is as follows:—The stud is formed in two parts, the top and bottom, each carrying a tubular piece of metal, &c., fitting one into the other. The inventor places a helical or spiral spring in one tube, which is secured at both ends to the top and bottom piece; as the folds of linen are placed over the top of the stud, the spring expands, according to the thickness of material, and yields and presses against the said linen, so as to prevent the same from leaving the stud.—Patent abandoned.

2196 B. F. STEVENS. *Improvements in burning petroleum and other hydro-carbon liquids for the production of heat and light, and in the apparatus or means employed therein.* (A communication.) Dated July 29, 1867.

This invention consists, first, in so placing the apparatus for producing a mixture of hydrocarbon spray and air, relatively to the heat produced by the combustion of such mixture, that the apparatus itself will not be subjected to the action of the heat, and will, consequently, not be liable

Digitized by Google

to be clogged or rendered unserviceable by the deposition of solid carbon or of tar, which depositions have been discovered by extensive experiments always to follow when the apparatus is itself subjected to heat. Second, of a peculiar adaptation of means for adjusting the relative quantities of steam and liquid hydro-carbon employed, so as to obtain the best economical result; and, third, of a mode of effecting a thorough mixture of hydro-carbon liquids with air to be used as illuminating gas.—Patent completed.

2197 A. HOLLOWAY. *A new or improved elastic clasp or lock suitable for pocket-books, purses, wallets, or any kind of leather cases.* Dated July 30, 1867.

This elastic clasp is composed of an oblong box for the upper part, and a tongue or slide of metal acted upon by a spiral spring, or springs, which gives the elastic property, which forms the principal feature of the invention. The catch or hook of this slide is formed by cutting a hole in the slide in the shape of a horse-shoe or shield, the tongue of metal forming the interior of the hole being the hook or catch for fastening it to the lower part of the clasp. The lower part of the clasp is composed of a flat plate of metal, with a small staple or bow riveted in the side of the above-named plate, which forms the lower half of the said clasp; under this staple the tongue of metal forming the centre of the horseshoe-shaped hole in the side of the upper parts of the said clasp passes for fastening the two parts together.—Patent abandoned.

2198 A. WATT. *An improved fertilizing compost.* Dated July 30, 1867.

This invention consists in forming a compost for horticultural and other like purposes by the employment of glycerine. To carry out the invention the patentee proceeds as follows:—He takes peat, rotted fibres, loam, leaf mould, or other fertilizing substances, to which he adds glycerine, or a solution of glycerine, the object of which is to keep the soil in a moist state for a longer period than would be the case when water alone is employed.—Patent completed.

2199 J. B. A. MENAGE. *Improvements in the construction of the lamp commonly called the Moderator Lamp.* Dated July 30, 1867.

This invention consists, first, in dispensing with the moderator rod, and using a simple oil tube for the oil to pass up to the burner, without any rod within it, and in regulating the supply of oil to the burner by contracting the diameter of the oil tube at the upper end thereof to a suitable extent to regulate the supply that shall be delivered to the burner. Second, in fixing to the lower end of the oil tube an inverted cup, into which is fitted another cup, and this latter cup is provided with a disc of wire gauze (or a plate perforated with very small holes); the latter cup operates as a filter through which the oil must pass before it can ascend into the oil tube, whereby the oil is filtered, and is wholly or partially freed from the impurities which may have collected in the oil reservoir. —Patent completed.

2200 J. JONES. *An improved chemical or compound for extinguishing fires and destroying explosive fire-damp in coal mines.* Dated July 30, 1867.

The patentee takes cyanides and oxides of manganese, magnesium, iron, sodium, potassium, carbon, or any other oxides or cyanides, muriatic acid, chloric acid, sulphuric acid, nitric, carbonic, acetic or any other acids; caustic liquor, caustic soda, caustic lime, iron, copper, potass, or any other caustics; ammonia, lime, soda, carbon, potass, or any other alkalies, or what these separately or together are composed of or produce, whether they be gases, liquids, or solids mixed in a suitable quantity of water. He selects one or more of the said articles in quantities of each as circumstances may require for extinguishing any particular kind of fires, such as cotton or other mills, buildings, or materials, oil warehouses, gunpowder magazines, greek fire, fires of sulphur, and phosphorus, in the process of melting metals, and for destroying explosive firedamp in coal mines, or for preventing combustion of the various aforesaid inflammable materials. He keeps the aforesaid articles separate from each other, and from water by means of separate vessels, distinct compartments, or by any other means, till used or required for use.—Patent completed.

2201 W. GADD and J. MOORE. *Improvements in looms for weaving.* Dated July 30, 1867.

Here the front of each shuttle box, or a part thereof, is free to turn upon a pin at or near its end farthest from the yarn, and such movable fronts are on their inner surfaces next the shuttle somewhat of the form of the "swell." These movable box fronts, or parts thereof, are held in position by springs with stops, which may be adjustable, to prevent the ends of these movable parts next the yarn from being pressed in too close, so as to prevent the entrance of the shuttle. By these means the shuttle may be held close to the box back during the whole time of its delivery with a gentle pressure, and its motion when thrown may be direct across the reed. These movable fronts or portions thereof thus also act on the shuttle as the ordinary "swells."—Patent completed.

2202 J. HAWORTH and E. HAMER. *An improvement in rollers used in machinery for doubling cotton and other fibrous material.* Dated July 30, 1867.

This invention consists in substituting rollers made of stoneware or earthenware for the wooden rollers. The stoneware or earthenware rollers are turned up true before being glazed or enamelled, a hole being made in the centre of each roller into which fits a cast-iron axis.—Patent abandoned.

2203 J. H. BROWN and W. BULL. *Improvements in the manufacture of hats, caps, bonnets, and other coverings for the head, and the foundations thereof, or similar articles, and in the means and appliances for producing the same.* Dated July 30, 1867.

Provisional protection has not been granted for this invention.

2204 A. MURRAY. *Improvements in apparatus for hauling vessels or other heavy bodies into deep water.* Dated July 30, 1867.

Here one improvement provides for the use of one or more powerful capstans, windlasses, or crabs worked by steam or other power on board of a vessel other than the stranded vessel, and which other vessel is to be placed between the stranded vessel or heavy weight to be moved, and one or more heavy anchors laid out in the direction in which it may be desired that these should be moved, and the improvement consists in placing the capstans, windlasses, or crabs on the same base plate with the bollards or bolts or apparatus to which the towing ropes or cables from the stranded vessel or heavy weight are attached, or in connecting these parts together by plates or bars, so that, when the strain in opposite directions is brought upon them, it will not pass through the framework or component parts forming the structure of the vessel in which they are placed.—Patent completed.

2205 C. MAYO. *Improvements in propelling and steering vessels.* Dated July 30, 1867.

According to this invention, in order to apply the motive power under the most advantageous conditions, it is proposed to make one or more tunnels passing through the vessel from before aft, in such a position that the axis of the tunnel or the resultant, in case of more than one, shall pass through the centre of resistance in a direction parallel to the surface of the water. And it is further proposed to place the propelling instrument (which the patentee prefers to be a screw in the tunnel revolving on an axis coincident with that of the tunnel) as near as may be to the centre of gravity of the vessel.—Patent completed.

2206 A. JAMES. *Improvements in needle-cases and wrappers.* Dated July 30, 1867.

One part of this invention consists of a needle case made of paper, and pasted in the form of a flat tube open at both ends. One end of the flat tube is cut away at one side, and the remaining side is made of a nearly semicircular figure, and constitutes a flap. When the flat paper tube is folded near its middle, the before-mentioned flap can be inserted in the open end of the tube, thus forming a flat case.—Patent completed.

2207 S. M. MARTIN and S. A. VARLEY. *Improvements in signalling upon railway trains, parts of which apparatus are applicable to electric telegraphs generally.* Dated July 30, 1867.

This invention relates to improvements in the arrangement and construction of parts of the apparatus and galvanic batteries for electrical train intercommunication, described in the specification of a former patent, granted to the present patentees, dated April 5, 1866 (No. 966). The patentees make the connections between vehicle and vehicle by means of spring hooks-and-eye couplings; the hooks are made by preference of steel, and the eyes of malleable cast iron, and may be galvanized for their better preservation. The spring hooks grip the eyes when the connections are coupled up, and are provided with a stop to prevent the hooks from being opened beyond a certain fixed amount, in order that they may not be unduly strained; or they are so constructed that they open and allow the eye to be pulled out if subjected to undue violence. To economize electric force, and at the same time to give a heavy blow upon the bell, they construct an apparatus which they call an electric lock. In this apparatus the attraction of a soft iron armature which takes place when the circuit is closed liberates a light lever, which, in its fall, liberates a second lever, and this second lever knocks away a detent, liberating a heavy hammer actuated by a powerful spring. As the apparatus just described is somewhat complex in its construction, they prefer, in most cases, to employ a modification of it, which may be employed either as a continuous ringing bell, or for liberating a detent and releasing a hammer actuated by a spring. They construct the electro-magnets which form part of and actuate the alarums in the following manner:—They take a piece of soft iron of a suitable size and length for the core, and flatten it out in the centre. They drill a hole through the flattened portion, and wrap insulated wire round the soft iron core. The two extremities of the soft iron core are usually connected by a soft iron bridge. The central portion is now divided, or very nearly so, and a piece of soft iron is mounted on an axle, and moves just freely in the space in the centre of the electro-magnet. This axle passes through the centre of a metal bar, which they call the striking lever, and to which it is attached. A hammer is attached to one end of the striking lever, and a balance weight slightly heavier than the hammer to the other. The normal position of the striking lever, and the piece of soft iron working in the centre of the electro-magnet, is nearly at right angles to the core of the electro-magnet when the circuit is open. When the circuit is closed, the piece of soft iron mounted on the axles arranges itself in the same direction as the core of the electro-magnet, moving nearly a quarter of a circle, and causing the hammer to strike a bell; the striking lever may be made to knock away a detent and release a heavy hammer actuated by a powerful spring. To make this alarum ring continuously when the circuit is closed, the balance weight at the lower end of the lever, just previously to the bell being struck, raises a lever which they call the make and break lever, and divides the circuit. The striking lever now assumes a vertical position, and an arm projecting from it comes in contact with the make and break lever, and forces it into contact with an insulated piece of metal, and again closes the circuit. The make and break lever is mounted on an axle, and is either a permanent magnet, one pole of which works between two pieces of soft iron, or it is made of soft iron, and works between the poles of two permanent magnets.—Patent completed.

2208 B. DOBSON and J. COCKER. *Improvements in machines for spinning and doubling.* Dated July 31, 1867.

This invention is not described apart from the drawings. —Patent completed.

2209 B. DOBSON and W. SLATER. *Certain improvements in carding engines.* Dated July 31, 1867.

This invention relates to the carding engines, for which letters patent were granted to G. Wellmann, September 11, 1860 (No. 2190). In those carding engines the top flats were raised and lowered by a cam, or by a series of curves on the face of the lifting wheels acting on pins in the slides in the radial arms. Now, this invention consists in dispensing with these cams or curves and pins, and lifting the top flats by a bowl on the lifting wheel acting on a curved surface on the slides, which are drawn down by springs as soon as the bowls have passed; by these means the top flats are rapidly raised and lowered again into their proper working place, and thereby better work is produced and time saved. Another part of the invention consists in the application of a ratchet wheel to the cross driving shaft, and a catch to the radial arm, to prevent the said shaft from moving in the wrong direction.—Patent completed.

2210 M. PUDDEFOOT. *An improved plough.* Dated July 31, 1867.

This invention consists in giving to the plough beam a short bend or shoulder near the middle of the furrow, a few inches in front of the mould board, so as to reach an inch or two over the unploughed land, and leaving room for a wheel to pass between the beam and mould board along the furrow, a hole being formed in the beam towards the hinder part of the mould board for the axletree. One handle is fixed to the mould board in like manner to the share, and the other, together with the colter, to the beam for light land, employing for heavy work a strengthening bar and brace connecting the front of the beam axletree and mould board. The said axletree is passed through the beam at one end, and the bar brace and mould board through the other, or otherwise; two small wheels fixed to the beam are also to be employed on wet or boggy land, as also irons similar to colters for breaking the clods before the colter comes to the next furrow; and for preventing the fall or flying off of the plough, in connection with which a drill is employed for sowing the seed.—Patent abandoned.

2211 M. J. FEARNLEY and C. SMITH. *Improvements in looms for weaving.* Dated July 31, 1867.

This invention consists, first, of an improved positive "taking up motion" for enabling the fabric to be wound on the cloth in a perfect and regular manner. The patentees employ the ordinary ratchet wheel, driven by a propelling catch from the slay sword, and fix to the shaft of the ratchet wheel, or cast to its boss, a toothed wheel gearing into a toothed wheel working on a stud in a lever connected by a rod to a bar or rod resting on the cloth in the cloth beam. To the boss of the last wheel is fixed a plain wheel or plate carrying a number of catches, catching into a second ratchet wheel fixed to a shaft working in a stationary bearing, which shaft is geared by pinions and toothed wheels with the shaft of the cloth beam, and as the beam increases in diameter the plate and catches rise with it. When the loom is working, the ordinary ratchet wheel gives motion by the gearing to the plate and catches, and turns the second ratchet wheel, gearing, and cloth beam, and as the cloth increases in diameter, the plate and catches are raised so as to cause the catches to take less and less of the teeth of the second ratchet wheel, until the beam has attained its full diameter, and thus enable the taking up to be uniform and positive. Second, for "letting off" motions, the yarn beam has to be gradually increased in speed as the yarn is wound off, and, when desired, the foregoing arrangements can be applied to the yarn beam by simply reversing their actions.—Patent completed.

2212 J. M. HOCKING. *Improvements in the means and apparatus for condensing noxious smoke and vapours.* Dated July 31, 1867.

Here the noxious smoke and vapours are drawn by an air pump, worked by steam or other power, from the furnace of furnaces through a pipe or pipes connected with such furnace or furnaces into one or more air-tight cylinders or cisterns partially filled with water; if more than one, then they are connected together by flues or pipes inserted in such cylinders or cisterns. Into and within each of such cylinders or cisterns the patentee inserts a spindle, and on the spindle within the cylinder or cistern he connects discs or fans, spokes or projections, which can be made of metal, and have other projections, angular or otherwise, formed on one or both surfaces. During the passing of the noxious smoke and vapours from the furnace or furnaces through the cylinder or cistern of water, the spindles upon which the discs, fans, spokes, &c., are fixed are made to revolve in the water within the cylinders or cisterns. These discs, fans, spokes, &c., when revolving, powerfully agitate the water, thereby arresting and separating the ores, particles of ores, metallic fumes, or mineral acids, contained in the said noxious smoke or vapours, and condense or cause the deposit of the same on the bottoms of the cylinders or cisterns.—Patent completed.

2213 G. GORDON. *Improved processes and apparatus to be used in the manufacture of sugar, and in sawing, cutting, or forming the same into cubes for use.* Dated July 31, 1867.

This invention is not described apart from the drawings. —Patent completed.

2214 W. R. LAKE. *An improved machine for manufacturing weavers' harness.* (A communication.) Dated July 31, 1867.

This invention is not described apart from the drawings. —Patent completed.

2215 J. C. C. AZEMAR. *Improvements in boxes or apparatus for holding pieces of paper or other material for use or distribution.* Dated July 31, 1867.

Here a loose board has two bands attached to it, which bands are carried up over rollers, and have weights attached to their ends. The under side of the board has a spring attached thereto which exerts a counter action against the weights, so that the board which carries the paper is always forced up with about the same amount of power. These parts are enclosed in a box, the lid of which has an opening at the front; this opening, together with an opening at the top of the front side of the box, allows the top piece of paper to be withdrawn. The underside of the lid becomes thinned towards the front, so as to exert a gradual diminution of pressure.—Patent completed.

2216 C. E. BROOMAN. *Improvements in firearms.* (A communication.) Dated July 31, 1867.

This invention is described and illustrated at page 124 of the present volume of this journal.—Patent completed.

2217 J. SAXBY. *Improvements in the construction of locking apparatus for governing the movement of railway points and signals, and in the mode or method of applying, combining, and actuating such apparatus.* Dated July 31, 1867.

We cannot here devote space to the voluminous details of this invention.—Patent completed.

2218 W. SNELL. *An engraving machine.* (A communication.) Dated August 1, 1867.

This invention consists, chiefly, in a method of combining with a graving tool or bit a stylus or tracing point, and a holder, to support the plate or object which is to be wrought upon, so that, as the tracing point is made to follow the lines of the pattern, corresponding motions will be imparted to the graver or bit, and a fac simile of the same, or a changed scale of proportions of the pattern, will be produced upon the surface of the object to be wrought upon.—Patent completed.

2219 F. A. CALVERT. *Improvements in machinery and apparatus for cleaning and preparing fibrous substances, and for opening twisted yarns and woven fabrics.* Dated August 1, 1867.

This invention relates to a former patent granted to the present patentee, dated March 24, 1866 (No. 869). In the specification of the said patent, referring to the machin e

Digitized by Google

for cleaning and preparing wool, cotton, &c., the patentee described a series of lifting bars and combs, acting in combination with the main toothed drum, or fine comb cylinder. Now, the present improvement consists in dispensing with the lifting of the said comb bars, and employing in lieu thereof one or more swivel bars, or revolving rollers, to which the toothed combs are attached. Also referring to the machine for preparing fibrous substances, and for opening twisted yarns, and woven fabrics, he described a series of blades and combs actuated by cams, and guided in slots. Now, the present improvement consists in making the combs to vibrate on centres, instead of lifting them, as heretofore.—Patent completed.

2220 J. H. JOHNSON. *Improvements in umbrellas.* (A communication.) Dated August 1, 1867.

The patentee claims, first, constructing umbrellas with a surrounding gutter, and discharge spout of flexible material, as described. Second, the peculiar combinations and arrangements of apparatus in connection with a flexible gutter and discharge spout attached to an umbrella for the purpose of opening and closing such gutter by the act of opening and closing the umbrella, and permitting of the folding up of the gutter and supports with the cover of the umbrella, as described. Third, the peculiar construction and arrangement of supports for the aforesaid flexible gutter, whereby such gutter is rendered self-opening without the necessity for special cords or appliances attached to the umbrella mechanism, as described.—Patent completed.

2221 F. H. HOLMES. *Improvements in apparatus for the production of the electric light.* Dated August 1, 1867.

This invention has for its object the production of the electric light with a reduced speed of rotation, or the increasing the intensity of the light with the same speed of rotation now adopted. According to one part of this invention it is proposed to place round the axis or shaft of an electro-magnetic machine a series of armatures, varying in number from, say, sixteen to forty, such armatures being all disposed parallel with the shaft; a corresponding number of electro-magnets are fixed to a frame which surrounds the armatures above referred to. Or the inventor places round the main shaft, and parallel with it, from sixteen to forty electro-magnets, and attaches to the frame which surrounds them a corresponding number of armatures. In either case he obtains the electric light by a velocity of revolution of the shaft ranging from 400 to 60 revolutions per minute, which is a much lower rate. Another part of the invention consists in winding on the electro-magnets, and on the armatures, or on the electro-magnets only, a double or treble set of coils of either flattened or round wire, for increasing or diminishing the light by increasing or diminishing the power of the electro-magnets, since the current which produces the magnetism can by this arrangement be passed through the whole of the wire (namely, the compound coil), or through either of the simple coils.—Patent abandoned.

2222 D. D. KYLE. *Communicating or signalling in and with railway trains.* Dated August 1, 1867.

Provisional protection has not been granted for this invention.

2223 R. B. BOYMAN. *Improvements in the machinery for propelling vessels and aerial conveyances by reaction.* Dated August 1, 1867.

This invention is not described apart from the drawings. —Patent completed.

2224 J. QUIN. *Improvements in the preparation of hose for conveying water, which improvements are also applicable for the preparation of woven fabrics for cart covers and other similar purposes.* Dated August 1, 1867.

This invention relates to the manufacture of seamless woven flax hose pipes, cart sheets, sail cloth, or other fabrics composed of flax, cotton, hemp, or an mixture of two or more of such materials, and consists, first, of a special mixture or preparation in which the yarn previously to weaving (or the cloth after it is woven) is steeped for preventing the rotting or decay of the fibre from damp or otherwise, and also to prevent the deleterious action of the sulphur upon such fabrics during the steaming process after they have been coated with the compounds. Secondly, the invention consists of a preparation of india-rubber and other materials, to be applied as described, to one side of the hose or fabric to render the same waterproof and pliable. And, thirdly, in a special solution or preparation to be applied to the reverse side of the hose or fabric to further protect the same against rotting.—Patent completed.

2225 R. NEWHALL. *Improvements in the manufacture of cases, enveloped, or wrappers for needles and pins.* Dated August 1, 1867.

This invention consists in making the cases, &c., for holding certain quantities of needle, or pins, say, for example, quarter packets or hundreds, by cutting out all the parts which subsequently form the case in one piece of paper, previously outlined to the shape, if desired, without any separation of such parts. The blank thus produced presents an oblong centre, two side wings and top and bottom flap pieces, one or both of such flaps having pointed or curved ends; each of the side wings are then slit or cut in their width into three parts, and the top and bottom flaps are also indented with a slit. The parts may now be folded inwards, the two centre portions of the side wings being closed and secured upon each other, the remaining parts of the side wings merely folding so as to be easily opened for the readier exhibition or withdrawal of the needles or pins.—Patent completed.

2226 W. R. LAKE. *Improvements in pocket knives.* (A communication.) Dated August 1, 1867.

This invention is not described apart from the drawings. —Patent completed.

2227 W. R. LAKE. *Improvements in breech-loading fire-arms.* (A communication.) Dated August 1, 1867.

This invention is not described apart from the drawings. —Patent completed.

2228 W. TRANTER. *Improvements in firearms.* Dated August 1, 1867.

This invention has reference to two former patents dated respectively July 20, 1865 (No. 1889), and August 17, 1866 (No. 2113), and consists, first, in elongating the screw for closing the rear end of the plunger by forming a tube with a hook at the front end thereof, for retaining the pin, in order to prevent its falling accidentally, and igniting the cartridge after it has been inserted in the barrel. By this arrangement the gun can be carried with safety when loaded, and, when required to be fired, it is only necessary to turn a projection formed on the screw into its position towards the right hand, thereby removing all impediment to the action of the striking pin. The projection is furnished with a spring and stud for retaining it in either of its positions. The front part of the stud or block on the striking pin is suitably formed for entering the hook and sliding out of it when required. And the invention consists, secondly, in a modification of the thrower for throwing out the cartridge case, and also of the plunger for acting in connection therewith. The plunger has a groove formed in the under side to within a short distance of the end, thereby forming a projection or shoulder adapted to catch upon the short end of the thrower, which is filed away on one or both sides for enabling it to slide in the groove of the plunger. A portion of the metal of the plunger is removed at the rear end of the groove to admit of its turning on its axis free of the short arm of the thrower.—Patent completed.

2229 J. E. NELSON. *Improvements in apparatus for conveying passengers and goods through the air.* Dated August 1, 1867.

Here the inventor employs a frame in the form of a circular disc, from the centre of which a portion is removed. This frame he makes hollow, and fills with gas, so as to give a certain amount of buoyancy to the frame. To this frame a car for receiving the passengers and goods is suspended, and below the car there is hung a weight which, by tackle, is capable of being moved fore and aft, so as to adjust the position of the centre of gravity in such manner that, when the apparatus has been carried up to a distance from the earth, and is then set free, the apparatus, as soon as it commences to fall towards the earth, may assume a more or less inclined position, dependent on the distance of the centre of gravity from the centre of the frame. The inclination thus given to the apparatus will cause it, as it descends, to skim through the air, gathering lateral velocity instead of falling directly to the earth. There are various other features described in the specification.—Patent abandoned.

2230 S. HIGGS. *Improvements in miners' safety lamps.* Dated August 1, 1867.

Here the gauze of the ordinary Davy lamp is encased in a tube made partly of glass and partly of gauze. This tube or casing forms of itself a separate safety lamp, and encloses the whole of the Davy lamp. Instead of the ordinary wick, a flat plaited wick dipped in a preparation of tallow is substituted.—Patent abandoned.

2231 J. BIRCH. *Improvements in machinery to be employed in the manufacture of wax vesta matches, and for other purposes.* Dated August 1, 1867.

This invention consists of certain new arrangements or combinations (the details of which we cannot produce here) of the parts of machinery for cutting into the required lengths the tapes or wax threads for vesta matches, and delivering the cut-off lengths into laths or supports preparatory to dipping the ends of the same into the composition with which they are required to be tipped. —Patent completed.

2232 J. POOLE. *Improvements in forming shafts, rollers, drums, and wheels with india-rubber surfaces.* Dated August 2, 1867.

Here the inventor divides the metal axis into two parts, or forms the same with an opening through the centre, extending from journal to journal; through this opening he passes a thin sheet of vulcanized india-rubber, which he turns or rolls up upon the metal. He then rolls the remainder of the sheet around the axis, and fastens the opposite edge, which is tapered, by screwing or otherwise. And in order to prevent the rubber from elongating he fixes metal collars upon the ends of the shafts. Other methods are included in the specification.—Patent abandoned.

2233 F. L. H. DANCHELL. *Improvements in machinery and apparatus for preparing, shaping, and drying peat and other substances.* Dated August 2, 1867.

The nature of this invention consists, first, in the general arrangement of the machinery for macerating or preparing the peat, or other vegetable or mineral substances, for forming it into discs or blocks, and delivering the same into troughs which are deposited by trucks, tramways, and guide rollers on the ground, on which they are left to dry by exposure to the atmosphere. Second, in the general arrangement of the machinery for preparing the peat, or other vegetable and mineral substances, for forming it into blocks, and delivering the same on to a series of endless travelling bands, by which the blocks are moved to and fro in a drying stove, and turned over at each end thereof; also in the arrangement of apparatus described for distributing heated air or currents of air in the drying stove.—Patent abandoned.

2234 J. EDWARDS. *Improvements in machinery or apparatus for actuating and locking railway points and signals.* Dated August 2, 1867.

This invention consists in the application and use of screws as the main movers, instead of levers, as at present. —Patent completed.

2235 B. HARLOW. *Improvements in boilers or apparatus applicable to the generation of steam, and to other purposes.* Dated August 2, 1867.

The patentee claims the use in boilers or apparatus for the generation of steam, &c., of double tubes, or broad flat tubes, arranged, formed, or constructed, as described. Second, the construction of hollow double fire bars with one joint or connection only at each end, as described.—Patent completed.

2236 J. H. JOHNSON. *Improvements in hydraulic lifts, and in the mode of operating the same.* (A communication.) Dated August 2, 1867.

This invention consists, first, in the use of an open or slotted column within which a flexible metallic packing band or blade is fitted, in order to close the said slot, such packing being opened and closed again as required by an arm connected with a double piston which is caused to ascend inside the column by water pressure acting from below. The slot or opening in this vertical column is closed as fast as the piston rises by the before-mentioned internal flexible metallic packing blade, which is withdrawn from the slot (so as to open the same) at the part contained between the two pistons, in order to allow of the passage of the connecting arm to which the platform or platforms of the lift is or are to be attached. Another part of this invention consists in working hydraulic lifts in which a pressure of water is required by the aid of what is known as the Giffard injector, in lieu of by a force pump, or other like means of obtaining fluid pressure.—Patent completed.

2237 E. T. MARLER. *Improvements in the method of, and apparatus for, clarifying sugar, which improvements are also applicable to other similar purposes.* (A communication.) Dated August 2, 1867.

According to this invention jets of steam are introduced or applied in such manner as to be thoroughly disseminated through a body of highly heated saccharine juices in combination with Fuller's earth, animal charcoal, or other suitable defecating medium.—Patent abandoned.

2238 J. DEWAR. *Improvements in preserving substances for food.* Dated August 2, 1867.

Here the patentee preserves meat, fish, game, poultry, and eggs in a condition suitable for food for a length of time by subjecting them to the action of an aqueous solution of sulphurous acid in a special manner, as described. He employs a stronger solution than usual, and exposes the substances to it for a longer period than has hitherto been practised.—Patent completed.

2239 E. A. KIRBY. *An improved system of dispensing medicines and preparing drugs therefor, together with an improved portable miniature dispensary, and instrument case applicable to such system.* Dated August 2, 1867.

Here, according to one part of the invention, instead of keeping the drugs (whether fluid or solid) in bottles &c., containing indefinite quantities, as now invariably practised, the patentee encloses the drugs separately (either in a fluid or finely powdered state) in small air-tight envelopes or cases of gelatine, or other suitable material, each containing a certain definite or ascertained quantity or dose of the pure drug, the said envelopes or cases being enclosed in glass tubes, bottles, or other receptacles, duly labelled with the name of the drug, and the number of grains, minims, or other exact quantity, contained in each envelope or case.—Patent completed.

2240 W. HORTON. *Improvements in forge hammers.* Dated August 2, 1867.

This invention relates to such forge hammers as are used in the manufacture of tools, cutlery, &c., and consists, principally, of an arrangement whereby the hammers are raised vertically in slides by cams compressing spiral or other springs, which, by their reaction, increase the force and momentum of the blow given by the hammers when released by the cams.—Patent abandoned.

2241 T. ALLEN. *Improvements in submarine telegraph cables, and in the mode of joining the same.* Dated August 2, 1867.

The patentee claims, first, the combining of iron or steel and copper wires in submarine telegraph cables in such relative proportions as to obtain the maximum of conductibility (for the sectional area of the conductor) with the minimum amount of iron or steel consistent with the desired breaking strain—that is to say, that the ratio of the iron or steel to the copper shall not be more than two to one, and it may be as one to one, as one to two, or as one to three. Second, the joining of submarine telegraph cables substantially by the means and in the manner described.—Patent abandoned.

2242 J. G. TONGUE. *Improvements in brakes for cotton lappers or scutchers.* (A communication.) Dated August 2, 1867.

This invention consists, first, in a stationary shoe secured to the back girt or cross rail of the machine, or other suitable support, in combination with a friction pulley arranged beneath it and swinging yoke, the upward motion of which brings the friction pulley into contact with the shoe to check the motion of the pulley, while the downward action of the yoke releases the pulley from contact with the shoe, and allows the pulley to turn. The second part of the invention in this connection consists in a peculiar construction of the swinging yoke, composed of a shield and bell-shaped lever or arm, between which two devices the friction pulley before referred to is situated. The third part of the invention comprises the swinging yoke shield, constructed to cover and protect the gear, operating in connection with the brake, and so as to form a bearing or support for the shaft of the pinion to which the friction pulley is secured. The fourth part of the invention includes a connecting rod or link combined with a foot lever, and weighted arm or lever, and whereby the brake is more effectually kept under the control of the operator. The fifth part of the invention includes a combination of the said shield gear arranged therein, friction pulley, stationary shoe, and sundry levers and weight or weights, constituting an entirely which gives to the brake a more perfect and controllable action.—Patent completed.

2243 J. SMITH. *Improvements in machinery or apparatus for bucking, bleaching, and cleansing textile fabrics and other fibrous materials.* Dated August 3, 1867.

In performing this invention the patentee makes use of a closed vessel or kier, furnished as usual with a grid, on which the fabrics or fibrous materials are placed; the upper and lower ends of the kier are connected by an external pipe, to which an apparatus is applied for heating the bleaching liquid contained in the pipe to a higher temperature than that in the kiln, in order to produce a constant circulation through the kier. The heating apparatus he prefers to use consists of an annular tube forming part of the pipe connecting the upper and lower ends of the kier, within which annular tube is introduced a perforated gas pipe, so arranged as to apply the oxy-hydrogen gas flame as the heating medium; but he does not intend to limit himself to the use of gas for heating the bleaching liquid.—Patent completed.

2244 J. and T. ELCE. *Improvements in machinery for spinning and doubling.* Dated August 3, 1867.

This invention is applicable to the self-acting mules in which the cam shaft is driven by positive gearing. The improvements consist in fixing a disc or other equivalent having two studs and bowls to the cam shaft, and in applying a spring so as to act on the said studs and bowls, whereby the cam shaft is brought into and held in its proper position after a change has been made. By this arrangement the cams are brought into the required position for separating instantaneously the two halves of the clutch box by which the cams are driven, thus preventing the points of the teeth of the clutch box from catching, and the consequent noise and wearing away of the teeth. —Patent completed.

2245 C. D. ABEL. *Improvements in combined gas and air engines.* (A communication.) Dated August 3, 1867.

The patentee claims, first, an improved arrangement of mechanism for imparting the motion of the piston rod to the engine shaft. Second, an improved mechanism for actuating the slide valve, and for raising the piston before the commencement of the up-stroke. Third, an improved construction of the slide valve, operating in combination

Digitized by Google

with the several gas and air passages in the cylinder and valve cover. Fourth, an improved construction of water jacket with provision for effecting the circulation of water therein. Fifth, improved mechanism for imparting the motion of the piston rod directly to a mill shaft by an endless band, all as described. The specification of this invention is too elaborate to be quoted here in detail.—Patent completed.

2246 R. BEWLEY. *Improvements in rotary pumps for raising water or other liquids.* Dated August 3, 1867.

Here, the case within which the revolving disc or impeller works for forcing the water, &c., admitted at its central part out through its circumference, as required, is constructed with an annular groove or space adapted to receive an annular ring, which is formed round the circumference of the revolving disc, the outer and inner circumferences of which ring, and the parts of the case in which the same works, are turned and bored to a truly cylindrical form. By this means a practically water-tight joint is obtained, without the risk of undue friction from the contact of the working parts. The parts of the case on each side of the groove or annular space in which the disc revolves (in which parts are formed the passages for admitting the water into the discs at its central part, and those for delivering it therefrom at its circumference) are respectively furnished with radial partitions, in order to prevent loss of power in giving rotary motion to the water. The case is also constructed with one movable side, in order to admit of the disc being taken out of the case and reinserted as required, without the necessity of disconnecting the pump from its supply and delivery pipes. This movable side is provided with a stuffing box through which the shaft of the revolving disc works. The revolving disc is constructed as above stated with a ring adapted to fit and work in a corresponding cylindrical space formed in the case, and has the requisite water passages formed in such ring, instead of being made as usual to extend from the circumference to near the centre of the disc, and these water passages formed in the ring have air in volute or other suitable curvature adapted to coincide as nearly as practicable with the direction of motion of the ends of the passages. These passages through the ring of the disc are made of an uniform cross section throughout, and they are proportioned in area to the quantity of water, and the height to which it is required to be raised by the pump; also to the speed at which the pump is to be worked.—Patent abandoned.

2247 C. TOUAILLON. *A new and improved means of utilizing all the parts of all sorts of feathers.* (A communication.) Dated August 3, 1867.

We cannot here give space to the details of this invention.—Patent completed.

2248 J. RUSSELL. *An improved system of flattening and straightening saws and similar plates or blades of steel during the process of hardening.* Dated August 3, 1867.

Here the patentee makes the blades or plates of steel red hot, as usual, and immerses them in oil, but before they become cold the bends, buckles, or twists, are taken out of them by placing them between strong surface plates and submitting them to great pressure.—Patent completed.

2249 A. BUDENBERG. *Improvements in apparatus for registering the pressure of steam in steam generators, and the pressure in hydraulic presses and other vessels or chambers, which improvements are also applicable to registering pressure and vacuum in steam engines, the vacuum in condensing apparatus, also to registering the combined pressure of the steam or other power employed to give motion to an engine, and the speed of such engine or other machinery, also to registering barometrical variations.* (A communication.) Dated August 3, 1867.

This invention is not described apart from the drawings.—Patent completed.

2250 J. F. and F. FENTON. *A new coffee injector.* Dated August 3, 1867.

This invention is not described apart from the drawings.—Patent abandoned.

2251 W. R. GRACE. *Improvements in harrows.* (A communication.) Dated August 3, 1867.

This invention consists, chiefly, in the use of a weighted roller in combination with the draught beam and frame in which the harrow teeth are secured. The roller is carried by an arm hinged to the draught beam, and the harrow frame is arranged to turn upon a central pin or stud projecting from the said beam, which is provided with an anti-friction roller arranged to run upon the top of the frame and keep the harrow level while in motion. The weighted roller bearing upon the frame causes the teeth of the harrow to enter the ground more deeply on one side of the centre of the frame than on the other side, and as the harrow is drawn forward, a rotary or circular motion is imparted to the frame around its centre.—Patent abandoned.

2252 J. T. HATFIELD. *Improvements in watch cases, which improvements are also applicable to locket and miniature cases.* (A communication.) Dated August 3, 1867.

The patentee claims, first, forming watch, locket, and miniature cases from hard rubber or gutter-percha, or other similar elastic, hard, or horn-like substance, by moulding the same in dies, substantially as set forth. Second, forming watch, locket, and miniature cases made of hard rubber or gutta-percha, or other similar elastic, hard, or horn-like substances, whether plain, embossed, or inlaid with metals or other substances.—Patent completed.

2253 G. W. DINSDALE. *Improvements in the construction and manufacture of traps for water-closets, drains, and other purposes.* Dated August 3, 1867.

The patentee claims, first, the construction of D or similarly shaped traps in two parts, the dip or inlet pipe being either formed as part of the shell or body, or in combination with the cover of the trap, as described. He also claims the construction of D or similarly shaped traps of earthenware in one or two parts, as described. Second, he claims the manufacture of D or similarly shaped traps by casting them complete in moulds with the dip and inlet pipe and outlet passage forming part thereof, the top or cover being cast or formed therewith, or separately therefrom, or in combination with the top or cover, as described.—Patent completed.

2254 W. W. HUGHES. *Improvements in apparatus for propelling vessels and pumping or raising water.* Dated August 3, 1867.

This invention relates to hydraulic pressure wheels to be driven by steam or other power for propelling vessels by forcing the water on which the vessels float through a tube or tubes having outlets at their sterns or sides below the surface of the water, as near to the line of the keel as may be found most convenient. Besides propelling, the apparatus is applicable for turning or stopping the vessels, as may be required, and also for pumping and raising water.—Patent completed.

2255 W. WILSON. *Improvements in felting machines.* (A communication.) Dated August 3, 1867.

This machine is composed of rollers, preferably conical rollers, revolving in the same direction, and mounted side by side on axes. The hollow between the rollers forms a bed on which the articles to be felted rest, whilst they are acted on by felters, either grooved or plain, which are above the rollers, and are rocked to and fro across the bed formed between them. The hat bodies, &c., to be felted are rolled up in a cloth and laid on the rollers, and as the rollers revolve, the felters are rocked to and fro. The rocking felters can be raised or lowered from the bed to diminish or increase the pressure on the work. The revolving rollers which form the leg for supporting the work are, by preference, partially immersed in hot water.—Patent completed.

2256 J. ANGUS. *Improvements in lamps burning with oils and other fluids.* (A communication.) Dated August 5, 1867.

This invention has for its object to prevent the explosion of lamps burning with volatile oils, or other volatile fluids, and consists in providing a tube, channel, or passage, either formed in one with or separate from the lamp, and passing down from the top to the bottom thereof. Both ends of the tube or passage are open, the lower end communicating with the interior of the lamp, while the upper end communicates with the external atmosphere, and is by preference surrounded by a small cup or reservoir formed in or upon the upper part of the lamp. The lower part of the lamp is filled with water in which the lower end of the passage is consequently immersed, and the volatile oil or other fluid floats on the top of the water. By this arrangement it will be seen that any increase of pressure in the lamp will relieve itself by forcing the water up the passage and out of the open end thereof and into the cup or reservoir, and thus any dangerous accumulation of pressure will be prevented.—Patent abandoned.

2257 L. V. HUE and C. ROZIERE. *Improvements in the means of moulding the subjects in glass or crystal for ornamenting them inwardly.* Dated August 5, 1867.

This invention consists, first, in a method of ornamenting glass by means of engraved or chased stamps or punches, which are applied on the hot glass, and the imprisonment of these ornamentations by covering them with other pieces of glass suitably fused, soldered, or welded on to the ornamental ones. Second, in the application of this method of ornamentation to the manufacture of all kinds of articles made in moulds by the press. Third, in the application of the same method to the manufacture of all kinds of articles made with blown cylinders, "manchons soufflés." Fourth, in the application of this same ornamentation to articles blown and doubled with an envelope "paraison" of white or coloured glass. Fifth, in the composition of boxes with mechanical stamps or punches, the said stamps being internal, that is to say, in the box; or external, that is to say, on the periphery of the box. Sixth, in the composition and arrangement of the mould for making lustre plates or liddle drops in two parts welded together and ornamented in the thickness of the glass.—Patent completed.

2258 J. DALE. *A refrigerator for cooling wort.* Dated August 5, 1867.

Provisional protection has not been granted for this invention.

2259 W. J. PUGHSLEY. *Improvements in obtaining sulphuric acid from the refuse pickle or liquor used in wire and galvanizing works.* Dated August 5, 1867.

In carrying out this invention the patentee proceeds as follows:—He places the used or refuse "pickle" or "liquor," when no longer fit for use, in a suitable vessel, and allows it to remain therein a sufficiently long time to permit such impurities as will settle at the bottom of the vessel to do so; the "pickle" or "liquor" will then become clear. He then conveys the clear liquid into a leaden pan placed on iron plates, with such brickwork as is necessary to support and protect the leaden pan, and by means of heat he concentrates this slowly until it has attained a specific gravity of about 1.250. After this he runs the liquid into vessels lined with lead, and allows it to remain therein four or five days to crystallize. The crystals thus obtained are sulphate of iron (commonly called "copperas.") He removes the crystals and puts the "mother liquor" again into a leaden pan, and evaporates as before to a suitable strength. The liquid is then run into another vessel and allowed to crystallize, as before. After this the liquid will be sulphuric acid of a sufficient strength and purity to be used as "pickle" or "liquor."—Patent completed.

2260 A. C. BAMLETT. *Improvements in reaping and mowing machines.* Dated August 5, 1867.

This invention consists, first, in giving motion to the chains or straps of self-swathe-delivery reapers by mounting a horizontal (or nearly so) spindle over the knife eye, and connecting it by gear to the chain rollers, the crop being delivered over the bottom bearing of the horizontal spindle. Second, in driving the reel (or its equivalent) in self-delivering sheaf reapers at different speeds, so as to regulate the size of the sheaves. The patentee uses two or more sets of pulleys provided with chains or straps, one set of pulleys being fixed on the reel shaft, the other set loosely on the main or other convenient shaft, and they are engaged and disengaged by a clutch movement. The pulleys are of different diameters, thus driving the reel or its equivalent at different speeds, which regulates the size of the sheaves. Third, in grass-mowing machines he mounts the intermediate spindle and the crank spindle on one bracket, which bracket is mounted in bearings attached to the frame of the machine, the bearings of the intermediate spindle forming a hollow spindle by which the bracket is mounted on to the frame. A second bracket, which carries the cutter bar, is mounted on the bracket already mentioned; or the second bracket may be made to carry both the cutter bar and the crank spindle. In order to take the weight of the finger bar and shoe off the ground, he uses a lever with a balance weight attached. To raise the cutter bar higher off the ground, he connects the regulating lever to the steerage pole by a double link-piece, so that when the cutter bar is raised, the frame will be raised as well, thus allowing the cutter bar to be raised higher than hitherto.—Patent completed.

2261 C. DE NEGRI. *Improved machinery for reducing wood to shreds to be used in the manufacture of paper pulp.* Dated August 5, 1867.

This machinery consists of two or more knives, straight-edged, and revolving rapidly on an axis parallel to the cutting edges and grain of the wood which is to be reduced. The wood is previously cut into pieces of an uniform length, slightly exceeding that of the knives, and the pieces are held in an oblong rectangular trough, open at the ends by means of a false side and wedge, the movable side and the fixed side opposite to it being furnished with pyramidal spikes, and advanced to the knives at a regular speed by a screw driver, or by level gear in connection with the knife shaft. The trough slides backwards and forwards between V's in a direction at right angles to the axis of rotation of the knives, so as to clear the revolving shaft, and so that the knives may barely clear the sides and bottom of the trough.

2262 J. G. TONGUE. *Improvements in the manufacture of wheeled and other carriages or vehicles.* (A communication.) Dated August 5, 1867.

This invention consists in making the body and other parts making up the outside or shell; also the seats, and, if desired, the wheels or running gear of a carriage or other wheeled vehicle, likewise the panels, dash-board, and, if desired, runners of a sleigh, of hard rubber or vulcanite, whereby durability and elegance is secured to the vehicle with comparatively little trouble or expense, and the carriage or other vehicle may be constructed with neatness and dispatch.—Patent completed.

2263 G. SCHNEIDER. *Improvements in breech-loading fire-arms.* Dated August 5, 1867.

This invention relates to that class of arm technically known as the breakdown. The first improvement has reference to the mechanism for maintaining the arm closed. For this purpose the patentee makes use of a bolt adapted to slide backwards and forwards in the breech-piece by means of a lever, which bolt, when the arm is closed, enters a cavity formed under the barrel or barrels. A spring is employed to keep the bolt in position. The second improvement under this head has reference to the pistons which strike the cartridge to produce its ignition. Hitherto these pistons have been raised by a spring (generally a helical spring) coiled round the piston. By this improvement the patentee raises the piston automatically by the closing of the gun without the use of springs, or any additional complication. The invention relates, second, to that class of arm in which the barrels and stock are rigidly connected, and the first improvement has reference to the movable breech-piece and its accessory parts. The next improvement has reference to the extraction and expulsion of the cartridge, which is effected in one single operation. For this purpose the patentee makes a perforation through the breech of the gun, in such a position that, after the extractor has drawn the cartridge entirely out of the barrel, whether it be charged or exploded, it will fall from the arm through such perforation.—Patent completed.

2264 J. HEATON. *Improvements in blast furnaces.* Dated August 5, 1867.

The patentee claims obtaining the desired draft or blast in blast furnaces by continuing the upper part of such furnaces into a chimney of the required height with openings for the feeding of the charges, substantially as described.—Patent completed.

2265 W. PRANGLEY. *Improvements in apparatus employed in athletic exercises.* Dated August 5, 1867.

Here two fixed uprights are used, which may be the two side posts of a door, or a gate, or they may be fixed for the special purpose of this invention. These uprights are required to be of greater height than the persons exercising between them. Across from upright to upright are two horizontal bars, which can readily be placed and retained at any desired height from the ground, according to the height of the person who for the time is taking exercise, the ends of such cross bars being received in brackets or sockets fixed or secured to the two uprights. One of these cross bars is for the hands of the person exercising. From the other cross bar two stirrups are suspended by elastic vulcanized springs (with handles) of a strength of elasticity adapted in each case to the person who for the time is using the apparatus.—Patent completed.

PROVISIONAL PROTECTIONS.

Dated October 28, 1867.

3029 G. Smith, Liverpool, brass and Britannia metal finisher. Improvements in marking boards used in the game of billiards, parts of which are applicable to registering the number of persons passing through pay-gates or conveyed by vehicles.

Dated December 7, 1867.

3482 P. R. Hodge, Adam-street, Adelphi, Strand, civil engineer. Improvements in machinery and apparatus for heating and forming metals for railway wheel tyres.

Dated January 30, 1868.

326 E. T. Mainwaring, Tipton, Staffordshire. An improved bale or metallic tie.

Dated January 31, 1868.

338 E. Andrews, Huddersfield, tailor. Improvements in trousers and breeches or other similar articles of wearing apparel.

Dated February 1, 1868.

353 A. Clark and A. van Winkle, Great Wild-street, London, soda apparatus manufacturers. Improved apparatus for manufacturing and storing aerated waters, and for transferring these and other liquids from one vessel to another. (Partly a communication.)

Dated February 4, 1868.

271 J. H. Johnson, Lincoln's Inn-fields. Improvements in the treatment of compressed or embossed wood. (A communication.)

Dated February 7, 1868.

419 W. Haun, Hetton Colliery, Durham, secretary to the Hetton Coal Company. Improvements in safety lamps.

Dated February 8, 1868.

[illegible]8 A. Philipp, Manchester. An improved apparatus [illegible] employed as a combined cigar, ash, and light holder, a[illegible]nist or other game marker.

[illegible] J. Howard, agricultural engineer, and F. T. Bousfield, engineer, Bedford. Improvements in the construction of steam boilers.

Digitized by Google

432 W. Cowan, Edinburgh, gas meter manufacturer. Improvements in the construction of the cases of gas meters.

434 H. Woodward, Hammersmith, mechanical engineer. An improved knife cleaner.

438 W. T. Sugg, Vincent Works, Vincent-street, Westminster. Improvements in valves.

439 W. B. Marston, Leeswood Vale Oil Works, near Mold, Flintshire. Improvements in lamps and apparatus for lighting railway carriages.

441 N. C. Szerelmey, Belgrave-road, Pimlico. Improvements in preserving wood.

Dated February 10, 1868.

445 W. Burgoyne, Cambridge-street, Birmingham, builder. Improvements in the construction of letter and invoice holders and sorters.

446 W. R. Lake, Southampton-buildings, Chancery-lane. An improved machine for scouring and cleaning grain. (A communication.)

447 F. Barnes, Southampton, surgeon, and D. Hancock, High Wycombe, Buckinghamshire, gas fitter. A new or improved method of, and apparatus for, working and communicating motion to signals on railways.

448 G. Jessop and B. Senior, Batley, Yorkshire, overlookers. Improvements in machinery for preparing wool and other fibrous substances for spinning, commonly known as the condenser carder.

449 C. E. Brooman, Fleet-street, City, patent agent. Improvements in combined pen and ink holders or fountain pen holders. (A communication.)

451 H. C. Tucker, Staverton, Devonshire, surveyor. Improvements in apparatus for shearing and clipping sheep and other animals.

452 H. Schlotter, Kostritz, near Gera, Reuss, Germany. An improved method of, and apparatus for, raising water.

453 J. Tansley, Bedford, cabinet maker. Improvements in apparatus for working the rollers of blinds, shutters, and maps.

Dated February 11, 1868.

454 H. A. Dobson, Knightsbridge, Westminster. An improved carriage spring.

455 T. J. Clanchy, Cheetham, near Manchester. Improvements in matches and fuzees.

457 C. M. Holland, Tan-y-Bwlch, Merionethshire. Improvements in the construction of the permanent way of railways and tramways.

458 J. W. Melling, Wigan, Lancashire, engineer. Improvements in machinery for cutting or excavating coal and other minerals.

459 C. and L. Vezhulst, Manchester, merchants. Improvements in the arrangement and construction of fireplaces. (A communication.)

460 J. R. Stoney, Leeds, engineer. Improved appliances for the consumption of smoke, and the economizing of fuel in steam boiler and other furnaces.

461 W. Pickard, Farsley, near Leeds, overlooker. An improvement in woollen condensing machinery.

463 G. Seamer, Milk-street, City, silk and velvet manufacturer. Improvements in the manufacture of silk fancy weavings.

464 F. Schafer, Piccadilly, manufacturer. A new or improved apparatus for testing eggs.

465 A. Brin, Rue des Acacias, Paris, civil engineer. Certain improvements in apparatus for generating and applying gas from air and hydrocarbon fluids for lighting and heating purposes.

466 J. S. Williamson, West Hartlepool, Durham. Improvements in drying machinery, useful for drying corn and other vegetable substances.

467 W. E. Newton, Chancery-lane. An improved apparatus for saving life in cases of shipwreck. (A communication.)

468 W. T. Woolley, Lever-street, St. Luke's. Improvements in locks or fastenings for purses, pocket-books, bags, and other articles.

469 J. Wenden, Alfred-street, Roman-road, Barnsbury, and S. P. B. Fussell, St. James's-road, Holloway, artists in stained glass. An improved process for ornamenting glass.

470 S. C. Lister, Manningham, Yorkshire. Improvements in looms for weaving cut pile fabrics.

Dated February 12, 1868.

475 R. Young, Glasgow, engineer. Improvements in apparatus for training, levelling, and dressing millstones.

476 R. C. Ross, Manchester. Certain improvements in mechanism or apparatus to be employed for cutting paper, pasteboard, textile fabrics, and similar substances or materials.

477 W. G. C. Hudson, Barbara-street, Arundel-square, Barnsbury, Islington. Improvements in revolving stands for culinary purposes. (A communication.)

478 S. B. Tucker, Parliament-street. Improvements in cartridge boxes or holders. (A communication.)

479 W. Wootton, Westminster Bridge-road, Surrey. Improvements in envelopes.

480 H. B. Condy, Battersea, Surrey, manufacturing chemist. Improvements in the manufacture of acetic acid, and in the preparation of materials to be used in the said manufacture.

481 J. G. Willans, St. Stephen's-crescent, Middlesex. Improvements in the manufacture of iron and steel.

Dated February 13, 1868.

483 S. Seville, Lees, Lancashire. Certain improvements in machinery or apparatus to be employed for sizeing and balling yarns and threads.

484 W. G. H. Taunton, Liverpool, engineer. Improvements in the construction of pumps, and in mechanism employed in working the same.

485 R. George, Kilburn, Middlesex. Improvements in gas stoves for heating and ventilating.

486 F. Grenier, Rue de la Coutellerie, Paris, civil engineer. An improved kneading apparatus.

487 W. E. Doverna, Liverpool. A new or improved fastener, applicable as a substitute for buckles and such like purposes.

488 J. Wood, Kenwick, Cumberland, civil engineer. Improvements in indicating the position of railway points, and in the apparatus or means employed therefor.

490 F. Tolhausen, Boulevart Magenta, Paris. New or improved processes and machinery or apparatus for brush making. (A communication.)

491 W. Woodfield, Redditch, needle manufacturer. Improvements in papering needles or making up packets of needles for sale.

497 G. Roberts, New Tothill-street, Victoria-street, Westminster. Improvements in candles.

495 W. R. Lake, Southampton-buildings, Chancery-lane. An improved mode of, and apparatus for, extracting and condensing the volatile portions of ores. (A communication.)

494 W. R. Lake, Southampton-buildings, Chancery-lane. An improved whip holder. (A communication.)

Dated February 14, 1868.

496 H. A. Bonneville, Sackville-street, Piccadilly. Certain improvements in compound of aniline colours. (A communication.)

497 H. A. Bonneville, Sackville-street, Piccadilly. Improvements in moderator or carcel lamps. (A communication.)

498 A. Lemasson, Rue Lagille, Paris. Improvements in the construction of dials or indicators for showing the distance travelled by cabs and other public conveyances, and the fares due for the same.

499 J. Steele, sugar refiner, and J. Hastie, engineer, Greenock, Renfrew. Improvements in apparatus for conveying and treating animal charcoal and sugar.

500 J. P. Lack, Basinghall-street, City. Improvements in albums, scrap, and other similar books. (A communication.)

503 G. V. Wisedill, Upper-street, Islington, jeweller. A new or improved ring for keys, and other useful purposes.

Dated February 15, 1868.

505 J. S. Raworth, Manchester, engineer. An improved mode of connecting and disconnecting revolving cylindrical surfaces.

506 R. Martin, Park-terrace, Horsham, Sussex, artist. An improvement in treating and deodorizing oils.

508 D. Whittaker, Blackburn. Improvements in healds or heddles, and other parts of looms, and in machinery or apparatus connected therewith.

509 W. Easterbrook, Albert-road, Kilburn, Middlesex, engineer. Improvements in machinery or apparatus for actuating, locking, interlocking, and controlling railway points and signals.

510 W. J. Bennett, Little Smith-street, Westminster, manager, and J. Jobson, Vauxhall Bridge-road, builder. Improved apparatus for separating the solid and watery particles of slop and sewage.

511 E. Cottam, Battersea, Surrey, engineer. Improvements in breech-loading firearms.

512 B. Farmer, Barrow-in-Furness, Lancashire. Improved breaking and crushing and hammering machinery, useful for crushing stone and minerals and hammering iron, steel, brass, copper, and other substances, and in forming wrought-steel bells.

514 J. Barlow, Queen's-street, Oxford-street, coach ironmonger and plater. Improvements in carriages. (Partly a communication.)

Dated February 17, 1868.

517 J. Clark, iron planer, and T. Vicars, Liverpool. An improved tobacco box and tobacco cutting machine combined.

518 W. H. Tasker, Bradford, glass blower and manufacturer. Improvements in, or applicable to, machinery for spinning and twisting fibrous substances.

519 A. H. Brandon, Rue Gaillon, Paris. Improvements in breech-loading firearms and cartridges, (A communication.)

520 J. P. Worrall, Orsdall, Lancashire. Certain improvements in the treatment of fabrics for the purpose of imitating skins of animals.

521 W. H. Wilkinson, Southampton-buildings, Chancery-lane. An improved system of type composition and mode of constructing and arranging the type cases for the same.

522 W. Lincoln, Southampton-buildings, Chancery-lane. An improved lamp burner.

523 J. G. Taylor, Boulevart de Strasbourg, Paris, manufacturer. Improvements in puzzles and puzzle chains, and in the applications thereof.

524 F. Chevassu, Rue d'Aboukir, Paris, merchant. An improved shirt.

525 J. Walker, Poole, Dorsetshire. Improvements in the manufacture of ornamental tiles, slabs, bricks, and other articles.

Dated February 18, 1868.

529 L. Wollheim, Gloucester-gardens, Hyde Park. Improvements in apparatus for barometrical and thermometrical purposes.

PATENTS APPLIED FOR WITH COMPLETE SPECIFICATIONS.

Dated February 19, 1868.

553 W. R. Lake, Southampton-buildings, Chancery-lane. An improved process of seasoning and preserving wood. (A communication.)

Dated February 22, 1868.

602 W. Krutzsch, City. Improvements in machines for washing and rinsing clothes. (A communication.)

Dated February 24, 1868.

616 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in artificial breasts. (A communication.)

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the "London Gazette," March 3, 1868.

2946 J. Anderson. Manufacture of felts.
2953 W. Barrett and C. Martin. Tuyeres.
2957 A. H. Brandon. Articulated artificial leg.
2968 J. White. Ventilating buildings.
2976 T. Welton. Ozonized bread.
2982 A. Chambers. Machinery for manufacturing files.
2987 J. Ellison and J. Stirk. Means for economizing fuel.
2990 J. Dodge. Machinery for cutting files.
2995 A. M. Clark. Transmitting motive power. (A communication.)
2997 C. W. Harrison. Preventing incrustation in boilers.
3000 W. and D. Fisken. Construction of steam boilers.
3011 B. Cooper. Removing knots from woollen cloth.
3015 W. E. Wiley. Holders for lead.
3020 J. J. Perry. Binding books. (A communication.)
3023 W. Kendall. Locomotive engines.
3034 A. J., W. B., and S. H. Waterlow. Machines for printing from copper.
3035 J. Glover. Furnaces for steam boilers.
3037 T. Bennett. Manufacture of spoons.
3054 J. Maddocks. Securing nuts and bolts.
3059 Earl of Caithness. Cleaning boiler tubes.
3060 A. V. Newton. Ventilating buildings. (A communication.)
3063 W. Hall, J. Wren, and J. Brandwood. Casting toothed wheels.
3067 O. C. Evans. Digging machinery.
3072 A. Chaplin. Portable distilling apparatus.
3076 J. Sturgeon. Machinery employed in getting coal.
3097 W. Dickinson. Joining leather.
3113 T. Briggs and W. E. Yates. Looms for weaving.
3120 R. Palmer and H. S. Hird. Manufacture of wheaten flour.
3121 W. Geeves. Panel doors.
3123 A. V. Newton. Roller or anti-friction journal boxes. (A communication.)
3126 R. Leake and J. Beckett. Machinery for polishing cylinders.
3146 B. T. Newnham. Tables.
3179 W. Payne. Clack pieces for pumps.
3180 C. B. Hodgetts. Tuyeres.
3219 A. V. Newton. Rotary engines. (A communication.)
3222 J. Morrison. Hem folders for sewing machines.
3299 W. R. Green and J. G. Freeman. Steam engines.
3401 T. Briggs. Machinery for drying woven fabrics.
3444 F. R. Ensor. Manufacturing lace.
3453 E. Walker. Construction of breech-loading ordnance.
3570 W. Conisbee. Cylindrical typographic printing machine.
3637 J. Davison. Rigging.
3676 J. Cockshoot and H. Weatherill. Railway brakes.
3702 J. Davison. Furnaces.
48 C. D. Abel. Process for removing sulphur from iron. (A communication.)
132 J. Lang. Printing music.
182 A. Bochkoltz. Self-acting valves.
238 D. Y. Stewart. Cast-iron pipes.
274 A. Middlemist. Increasing the heat in stoves.
311 D. Law and J. Wharrie. Manufacturing cast-iron pipes.
322 J. Grimes. Machinery for manufacturing the bottoms of boots.
345 J. Livesey. Material that may be used as a substitute for glass.
387 T. W. Walker. Manufacture of bricks.
428 A. Philipp. Cigar ash and light holder.
464 F. Schafer. Testing eggs.
475 R. Young. Dressing millstones.
476 R. C. Ross. Cutting paper.
483 S. Seville. Sizeing yarns and threads.
616 W. R. Lake. Artificial breasts. (A communication.)

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list, who have given notice of their intention to proceed, within twenty-one days from the date of the "Gazette" in which the notice appears, by leaving at the Commissioners' office, particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed February 28, 1868.

2461 J. Douglas	2493 P. F. Lunde
2463 J. and G. W. Dyson, and S. Martin	2506 G. T. Bousfield
2473 I. Dixon	2513 H. Carter and G. H. Edwards
2474 M. Hammerstein	2541 J. Whitham
2480 D. Nicoll	2844 T. Nelson
2489 A. Field and W. B. Nation	2977 F. J. Bugg
2492 A. E. Gelhaye	2993 H. Ritchie
	3190 W. and W. Campion

Sealed March 3, 1868.

2503 F. B. Dœring	2539 B. F. Stevens
2509 R. A. Jones and J. C. Hedges	2549 F. Tolhausen

THE

MECHANICS' MAGAZINE.

LONDON: FRIDAY, MARCH 13, 1868.

THE LAWS OF VOLCANIC ACTION.

THE grand and mysterious workings of Nature, as manifested in the extraordinary phenomena which man is privileged to witness from time to time, were once the subject of wild and extravagant speculation amongst the learned few, whilst the masses wondered ignorantly on in mingled terror and admiration. In the course of time, aided by the dim light of a dawning civilization, philosophy pushed on its inquiries, and advanced its theories a little nearer to truth. Later on, the cultivation of the sciences, exact and applied, carried men forward still further in the path of research and discovery towards their goal. And the development of science still continues to present to the finite mind of man the solution of many questions which, at no great distance of time in the past, were seemingly enwrapped in hopeless darkness. Repeated observation enables us to trace the recurrence of some of the occasional and startling phenomena revealed to us, to certain well defined causes, and to assign to them precise and infallible laws. Thus, the magnificent meteoric display of November, 1866, which, at one time, would have been—perhaps was—the terror of nations, was watched and waited for, and came to us the simple, yet sublime, fulfilment of scientific prediction. Nor was this all. It likewise definitively established the existence of a new class of bodies belonging to the solar system, which were formerly thought to be mere wanderers. Their origin, their nature, their course, and their functions, were all a solemn mystery. But science has placed them in a new light, and has revealed to us the existence of numberless members of our solar system, having an extraneous or cosmical origin, and revolving in definite orbits around the sun.

So, although in a modified degree, is it with regard to the thermal forces operating within the crust of our earth. We are all more or less acquainted with the aspect and nature of a volcano; we know, too, that it is by turns active and dormant, and that whilst in the former state clouds of vapour and flame, showers of dust and ashes, and streams of lava, or molten rock-matter, are emitted from the top at intervals. We have advanced upon the olden notions of the cause of volcanic phenomena, and can, in some degree, account for the convulsions of Nature which occur from time to time. But we are, as yet, a long distance from a perfect knowledge of the laws of Nature's operations in this respect. True, we have worked out two theories of its origin—the mechanical and the chemical. The former supposes an original igneous condition of the earth, and a cooled crust over a present molten interior, whilst the latter presumes the solid crust to contain an abundance of such metallic elements as develop heat on contact with water. But here we are forced to stop, and the very fact of the existence of two theories shows that we are as yet only on the threshold of the inquiry. To the questions—What is the cause of volcanic energy or the periodicity of its discharges? what is the law which regulates the shifting of its action from point to point?—science can give no satisfactory reply. And yet, at no distant time, all these matters may be readily accounted for, and may prove to be governed by some well-known law, the non-application of which at the present time may then be a matter of wonder. Seismography, or the science of earth shocks, is but a new study, yet it is one which—combined with careful observation of volcanic eruptions and their products—may lead to a determination of the laws which regulate these operations. An admirable opportunity for prosecuting these researches offers itself in the present protracted eruption of Vesuvius, inasmuch as peculiarities are observable which never before presented themselves, or, if they did, have passed by unnoticed. In the hope then, that it may prove of some service in directing attention to the subject, we place on record the distinguishing characteristics of the present eruption.

It is now just four months since the commencement of the present eruption, and during that time it has presented three distinct phases. Scientific observers apportion to the first phase the time between the night of the 12th of November and the 15th of January. The second includes the time between the 15th of January and the 11th of February; and the third extends from the last date to the present time. In the first period the volcano was in full activity; during the second interval it exhibited great varieties with less activity, whilst the third period is marked as one of diminution. This latest phase is remarkable for its varieties and for the confirmation of certain scientific facts. On the 11th of February the flow of lava was materially diminished, and it was thought that the eruption was nearly over. On the 12th, however, there was renewed activity, which continued until the 15th; explosions were loud and frequent, chiefly in the morning and evening, and were accompanied by the ejection of stones, and followed by comparative silence. During this period the lava presented some curious features in its course. It was almost invisible on the upper part of the cone without ascending to the summit, but on arriving there it became apparent that underneath a bed of lava which had suddenly cooled in an interval of repose, a tube had been formed, and was attached almost mechanically to the crater, into which the lava overflowed, running through its entire length to near the middle of the cone. In several parts, however, the volume and its violence are stated to have broken the tube, and then, through the openings, the pure lava, without any admixture of scoriæ, might be seen wending its course downwards. During these three days or so, shocks of earthquake occurred, and the apparatus of variation was disturbed. Sublimates were collected on the summit, but not in sufficient quantities to mark the end of the eruption. On the 17th, greater activity was perceptible, and its periodicity was confirmed; twice a day Vesuvius put forth all its energies, interesting equally the scientific and curious.

At this time the guides of Vesuvius, who reside in Resina, stated that shocks were felt in that town sufficiently severe to shake the doors and windows. They also said that columns of stones were shot into the air to a height of nearly 900ft. The flow of lava, too, progressed considerably, forming at the foot of the cone five different streams, which poured over like cascades. On the 18th the great cone again commenced roaring violently, and two shocks of earthquake were recorded in Resina. On this day, too, the summit of the cone fell in, and, obstructing the way, formed three craters, which threw out large volumes of stones. The entire cone was also observed to tremble for four or five seconds as if shaken by an earthquake, and later in the day the lava forced an opening in the direction of the Piano delle Ginestre, and flowed onwards in a stream of full ten metres in width. From that time to the end of the month the mountain continued to thunder, and to throw out masses of red-hot lava, which, dividing into many streams, presented at a distance a spectacle of singular beauty. Frequent, though slight, shocks have been felt at Resina and other places in the immediate neighbourhood, and on the night of the 27th there was one unusually strong. We have now brought the eruption down to the latest recorded observations, and have noticed all the leading features and peculiarities which we have gathered from an interesting letter of the "Times" correspondent, written on the spot. There are, however, some other points added connected with this subject, and which are worthy of especial note, as being the results of careful observations made by Professor Palmieri. In fact, these are of the highest importance, as tending to throw some light upon the laws which govern volcanic eruptions. We have already alluded to the periodicity of the eruptions, and it would now appear that the volcano is subject to lunar influence. Be this as it may, observation goes to show that the periods of greatest eruption are half an hour later every day, singularly coinciding with the evolutions of the planet.

Professor Palmieri, in writing on the general subject, says:—"The eruption of Vesuvius maintains the periodic character already described by us, hence there are no novelties. All that is to be noted are the hours of return, with their duration and intensity, which are of interest to the scientific rather than to the curious observer. Hamilton was the first who marked a diurnal period in a long-continued eruption, and from his limited number of observations, he believed that the recurrences were at fixed hours. In 1855, however, we had an opportunity of studying this phenomenon better, and we observed the daily 'retard' of each increase of the lava; now we have had the opportunity of confirming what we then observed. Were there a good path, we could tell travellers and guides at what hour they should be near the summit without any risk from the projectiles or burning lava." With regard to the nature of the materials which have been thrown out during the third phase, it is to be observed that the ashes and the sublimates have been in small quantities, which, according to Palmieri's own assertions on several occasions, indicate that the eruption is not near its termination. The sublimates which have appeared, however, on the smoke holes have been chlorure of copper and of lead, while the absence of chlorure of iron has been noted as remarkable, although on the top of the cone it has been found united with "oligisto" iron. We should not omit here to refer to the precision with which the instruments of the Observatory, one of which was the ingenious invention of Professor Palmieri, mark the subterraneous movements. It is said to be such that a person, even with the windows closed and without seeing Vesuvius, can tell what are the conditions of the eruption. More, we think, could not be desired, and, if desired, not attained.

We have now gathered together all the salient points and noteworthy details of this remarkable phenomenon. We have shown how scant and bare our knowledge is of the laws which govern these convulsions of Nature. We have pointed out that by careful study and application of revealed facts, and comparison of circumstances, we may in time be enabled in this, as in other departments of science, to speak with exactitude and certainty. No good purpose could be served, nor would any beneficial results arise, were we ourselves to speculate or theorize upon the ascertained facts before us. It is a subject which can only be approached through a long chain of close reasoning, and by tedious and painstaking research and patient observation. We can only now heartily commend the matter to the earnest consideration of those whose inclination, interests, or, possibly, duty, may lead them to an investigation of the whole circumstances. It is a subject full of the deepest interest, and although it may appear mysterious and difficult to approach, it will become plain on being resolutely pursued and carefully investigated.

Digitized by Google

Already in the present eruption we have the question of lunar influence, which was previously suspected, to a great extent confirmed, and we know not what else may be added to our knowledge before Vesuvius is again quiescent. At any rate, we have materials to work upon, and we may without presumption dive still more deeply into the secret of Nature's workings beneath our feet, since we have made ourselves so familiar with those above our head. Still, when all is done, when those secrets of Nature are mastered and the whole course of her working apparently made plain, we shall only be on the threshold of perfect knowledge. Our acquaintance with these things will doubtless only prove to us that there is much more behind. We shall end pretty nearly where we began, by confessing that "there are more things in heaven and earth than are dreamt of in our philosophy."

THE "TIMES" ON THE MINT.

IN the pages of the so-called "leading" journal of the British empire of Wednesday, the 4th inst., there appeared, with great prominence and much pretension, an article on the Mint. It bears reference to the Royal money manufactory on Tower-hill, but is so full of errors and positive mis-statements, with regard to that establishment, that it cannot be allowed to pass current without protest. From the opening paragraphs of the article in question, it might easily be inferred that the public were about to be fully instructed as to the mechanical and other processes carried on at the Mint. That idea is speedily dispelled, however, by the context, for no such information follows. The reader, on the contrary, is led, in the first instance, into an archæological maze as to the early mints of England, and in which the writer omits altogether to state that in the reign of Queen Mary all provincial mints were abolished, and one central mint was established within the Tower of London. In referring to the present Mint, the same authority states that since 1806 this "has been the sole coining centre for the British empire, where not only all the coins, from farthings to pounds, are struck, but where all medals for the army and navy, all gold medals for the Board of Trade, all Victoria Crosses, and all medal decorations of any kind awarded by the Government, are made and issued." The truth is, nevertheless, that no coins whatever were struck at the existing Mint till 1810; that copper and bronze coin has frequently been struck since that period, in very large quantities—thousands of tons—by contractors in Birmingham, and notably by James Watt and Company; that only one gold medal for the Board of Trade, and not one Victoria Cross, has ever been struck at the Royal Mint; and that many hundreds of other "medal decorations," awarded by the British Government, have been, and are now, produced outside its walls.

These are only a small sample of the many errors promulgated on this occasion with the stamp of the "Times'" authority. After making some startling assertions as to the time "when silver plate, and bars of copper, gold ornaments, and gold trinkets used to be left for coinage" at the Mint, and which certainly has not been the case within the last 200 years, the "Times" goes on to say that Mr. Peabody lately "sent £10,000 of old gold of all kinds to be made into sovereigns." This statement has not the shadow of a foundation. In fact, Mr. Peabody never did anything of the kind, and more than thirty years have elapsed since any private individual employed the Royal presses for stamping money, the last being the late Mr. Rothschild. It is further remarked that, "for the first time in the history of the Mint, not a single sovereign was struck there during the last year," and that "during nearly fifteen months not a pound sterling in gold has been added to the currency of the kingdom." Both these averments are at variance with truth. It has very frequently happened in the history of the Mint—and in its recent history, too—that a year has passed without any gold being coined. This was not so last year, however, for not less than half a million of "pounds sterling in gold" were struck at the Royal Mint and sent to the Bank of England in 1867. Similarly unfortunate for the "Times" are its remarks upon the silver coinage. It is observed of crown pieces that although "they are dying out of circulation in this country, yet that two thousand pounds' worth are annually struck at the Mint for the inhabitants of the Falkland Islands." What will the readers of the "Times" think when we tell them, on the best authority—that of official returns—that not one single crown piece has been struck at the Royal Mint since the year 1849, either for home circulation or for the Falkland Islanders. Crowns, half-crowns, and fourpenny-pieces are, indeed, rapidly becoming extinct, for not one piece of either denomination has been issued from the Mint for many years. This is a piece of information the "Times" does not give—but it is true!

After speaking of popular and unpopular coins, the first issue of florins is adduced as falling under the latter category. It is asserted that they were small in size, that the usual letters F.D. were omitted from their circumference, and that they were thence termed "graceless florins." In reality, the letters omitted in the legend on the small florin coinage were D.G., and not F.D., and the coins were known, not as "Graceless," but "Godless." Does the "Times" need to be told that F.D. is an abbreviation of Fidei Defensor, and D.G. of Dei Gratia? It would appear so. To enumerate all the mis-statements of the "Times" in its Mint article would demand more space than we can afford in our columns, for it literally bristles with them. One or two others, however, must be mentioned. It cannot be permitted to go forth uncontradicted that the Bank of England "sells its light sovereigns to jewellers, &c." It never has done, we believe, anything of the kind. Certainly, it does not do so now. Jewellers cannot "buy the cut sovereigns by the ounce or the pound." Light sovereigns withdrawn from circulation are really held by the Bank authorities until they reach a very large number, when they are re-cast into ingots. Jewellers who require sovereigns for their purposes do not need to buy them at all. They simply melt gold coins as they come to hand, whether light or heavy, and then reduce the standard of fineness of the resulting metal by the admixture of so much alloy (copper), as they find necessary. English sovereigns are, no doubt, melted down in large quantities every year, and used for trade purposes. This occurs because at the Royal Mint they are always made, with scrupulous care, of 22-carat metal, and it is easy to calculate how much of additional alloy will reduce them to any other standard. Where the "Times" obtained the knowledge of counterfeit coining which it imparts we do not know. Perhaps, its statements on this subject are exact, but in all other respects, assuredly, they are just the reverse. Had the writer of the article to which we have felt it a public duty to allude, studiously endeavoured to pervert the truth as to Mint proceedings, he could not have succeeded more effectually. It is more probable that hastily-obtained and ill-digested information is the cause of his shortcomings.

DIFFERENTIAL SATUROMETER.

A KNOWLEDGE of what is passing in the interior of a machine, and the manner in which the various parts are carrying on their respective functions, is unquestionably of paramount importance not only to the person in charge of it, but also indirectly to those whose safety, and possibly lives, may depend upon its being maintained in proper working order. To the marine engineer, one of the most essential points in connection with his duty, is to be capable of readily and accurately ascertaining the state of saturation of the water in the boiler, as both the duration of the material, and the economy of the fuel, are in a great measure dependent upon the degree to which that condition attains. The practical results attending the use of all indicators of saturation have not been very satisfactory, and reliance is chiefly placed upon the ordinary aerometers, in which the degree of saturation is obtained by allowing the water to enter a graduated gauge glass. In order to determine the effect of the temperature of the water, which is a necessary item in the investigation, a thermometer has frequently to be employed, the manipulation of which is attended with much risk and inconvenience. If the state of the water be not observed with a sufficient degree of care and frequency, it is manifest that deposits of salt will take place in the boiler. On the other hand, if the engineer, in his anxiety, be continually opening the communication, there will be a loss of heat incurred. A remedy for these contingencies would be found in an instrument which, without the necessity of any subsidiary operation, would indicate at any moment the saturation required to be ascertained. The differential saturometer, invented and patented recently by M. Coret, is calculated to afford this information, and in addition to indicating the state of the water, also records at the same time its level in the boiler, thus enabling the engineer to perceive at a glance, all that he requires to know with respect to the contents of the boiler. This instrument, moreover, registers the average saturation of the water. Its action is based upon the well-known principle of physics,—that if two liquids of different specific gravities, having the same temperature and exerting no chemical effect upon each other, be placed in two vessels or tubes communicating freely with one another, their respective heights under conditions of equilibrium will be inversely as their densities. From this it follows that if the specific gravity of one of the liquids be known, and the heights of the columns of fluid, the density of the other can be easily obtained. Putting D D^1 to represent the specific gravities and H H^1 the respective heights, we have

$$\frac{H}{H^1} = \frac{D^1}{D} \quad \text{or} \quad D^1 = \frac{II \times D}{II^1} = \text{the density required.}$$

The application of this principle is carried in the apparatus under notice as follows. In fig. 1, A B are two glass tubes placed as near one another as the vertical scale between them will admit. One of these, A, is connected with the feed water, and the other with that in the boiler. These indicators A and B are disposed in the manner usual in all marine boilers, with this difference, that in this instance one of them, A, instead of being put into communication with the water in the boiler, receives that coming directly from the feed pipe H by means of the auxiliary pipe E. A small cock r (see fig. 2) serves to regulate the flow of the water, which passes through the tube G into that of A, attains the height due to its density, and finally passes downwards into the boiler by the pipe D. The cock r permits only a small thread of water to enter at a time, sufficient to maintain the flow uniform, but not sufficient to allow of a greater amount of saturation taking place than what it possessed at its first ingress. It might be urged that a certain amount of initial velocity and disturbance is imparted to the contents of the tube A, owing to the action of the feed pumps, but this can be provided for. Moreover, even if it were neglected, the error would not amount to more than a quarter of a degree. At the lower extremity of the two pipes C and D is fixed a double cock R

Digitized by Google

arranged so as to cut off their communication with the boiler, while at the same time it leaves them free to communicate with one another. This is effected by turning the key c, placed outside the boiler, through a quarter of a revolution, by which the two apertures shown in the section of the cock R in fig. 4 are changed in position, and no longer allow the water to flow into the tubes. All things being put "au courant," the apparatus performs its duty in the following manner. The small cock *r* is opened to such an extent as not to allow the oscillations in the tube A to exceed in height the tenth part of an inch, an amount of no practical importance. The indications are constant, and are read off at once by the scale P (see fig. 1), and no further subsidiary operations are required. During a storm, when the rolling of the vessel prevents a comparison being made between the relative levels, in consequence of the oscillations produced in the tubes, the small cock *r* is closed, and a quarter turn given to the larger one R, which cuts off their communication at once with the boiler. The oscillations are then arrested, and a comparison,

FIG. 2.

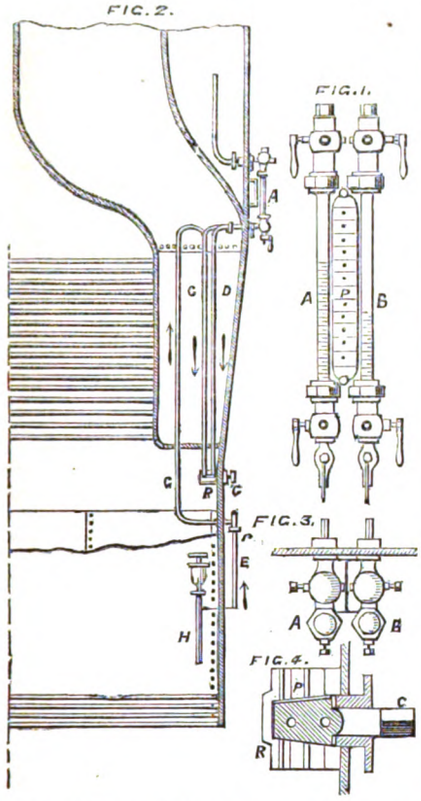

FIG. 1.

FIG. 3.

FIG. 4.

previously impossible, is made with accuracy and facility. It should also be observed that whenever the cock *r* is closed, all disturbing or vibratory action due to the working of the feed pumps is obviated, and that this cock may be maintained shut for nearly an hour, without causing any appreciable difference in the rate of saturation.

In order to effect a rigorous comparison between the two columns of liquid, when both the cocks *r* and R are opened, and the sea is tolerably calm, it is indispensable that the contents of the indicating tubes A and B should rise and fall cotemporaneously. To effect this satisfactorily, the two pipes C D should have the same internal diameter and the same number of bends, and the orifices of the indicators A and B should have identical dimensions, in order that the water should encounter an equal amount of resistance in each of the tubes, a circumstance altogether contingent upon a due observance of the above-mentioned precautions. These requisites, however, do not affect the construction of the pipe G (see fig. 1), which must be proportioned according to the dimensions and arrangement of the boiler. There is one point to be attended to respecting its position, which should be in the interior of the boiler, in order that its contents may acquire the same temperature as the water therein. Both the tubes C and D may be fixed outside the boiler, if such a disposition should be the more convenient. In fig. 1 the scale P is placed between the two indicating tubes A and B, and is graduated to degrees corresponding with those of Beaume. In every 3·28ft. in height of the column of liquid the divisions are 0·32in. apart, so that if the boiler allowed of a height of double this dimension, the scale could be read off at some distance. The principal and semi-divisions are uncovered, so that they may be seen at night, by means of a lamp placed between the scale. Owing to the sensibility and accuracy of this little apparatus the deposits of salt may be permitted to approach a convenient state of saturation, a too frequent repetition of extraction is avoided, and an economy obtained in the consumption of fuel.

VENTILATION OF PUBLIC BUILDINGS, UNDERGROUND RAILWAYS, ETC.

GENERAL MORIN'S paper on the ventilation of public buildings has just been published in the report of the annual meeting of the Institute of Mechanical Engineers, held last year in the Conservatoire des Arts et Métiers, at Paris. We quite agree with the General that the system of ventilating rooms at the top is a mistake. That admitting fresh air near or at the floor of a room, will not drive off the foul air at the top. Especially, it will not drive off the carbonic acid gas which is produced by the breathing of an assemblage of people, and the combustion of gas and other lighting material. An influx of cool fresh air near the floor, will rather tend to prevent the efflux of this gas. The specific gravity of this gas causes it to tend to the lowest parts of any room or place, and if free outlets were provided it would flow out; but as ventilation is at present provided for it cannot do so, openings at the ceiling or roof being provided for the outlet of foul air, and openings near the floor for the ingress of fresh air. Now, if all foul air were lighter than pure air, this simple arrangement would be perfectly successful, but it is not so; some is lighter than pure air and some is heavier. This being the case, what is to be expected from such an arrangement but very imperfect ventilation, which is the actual state of things in all places so ventilated.

Suppose a room, filled with people, and lighted up, and having the openings at the floor and ceiling closed till the air was thoroughly vitiated by the exhalations from the assembly and the combustion of the gas, let then the ingress and egress be opened, and what would take place? It must be remembered that the general density of the air inside the room would be less than the density of the air without, through rarefaction by the heat of the room, and it will be clearly seen that the external air will flow in, and the internal air will flow out, at both the top and bottom openings. The carbonic acid gas will tend to flow out at the bottom, and the lighter gases at the top, and the outer atmosphere will flow in at both top and bottom; therefore, ventilation can only take place by the slow mixing of the internal and external air. A current of air will not tend from the bottom opening to the top opening, which is the theory of the system. From this view of the matter it would appear that a third opening should be provided intermediately between the top and the bottom, where the pressure outward would be less than either at the top or bottom, so that a free ingress would there be afforded for the external air, and the lighter gases would pass out at the top, and the heavier at the bottom. Still there might be the objection to this intermediate opening, that it would produce a draught injurious to health. Yet we have seen churches and chapels ventilated by an oblique opening being made in the windows, so that the inflowing air passed upwards, and no draught resulted.

General Morin proposes that the ingress openings shall be at the top and the egress for the foul air at the bottom, so that the carbonic acid produced by the breathing of the people may be discharged near the source of its production. And this he considers will be best produced by suction, and to maintain this suction nothing more is required than an ordinary fireplace. We cannot exactly see that an ordinary fireplace would be very effective in producing a current sufficient to draw off the carbonic acid gas; but, at any rate, a close stove would, if it received the air to support combustion through openings in the floor from beneath the floor only. In this case the carbonic acid gas could be drawn off only by being rarefied in passing through the fire; but its presence would tend to lessen the heat: consequently, the draught. In many places a better way of producing a current would be by mechanical means—for example, by means of a fan, and this method would be especially suited to our Houses of Parliament, with the ventilation of which there has been so much trouble and expense and so little beneficial result.

Underground railways also might be so ventilated. In railway tunnels the apparatus might be made self-acting. The mechanical force of the passing trains might be used as the motive power of the fans. The fans might be directly driven by means of a weight actuating a suitable train of wheels, and this weight could be wound up by the passing trains in the following manner:—At each station let a machine for driving a fan be erected, with a lever extending under the rails. The rails might be made elastic, and to allow of a depression, which need not be of more than an inch—it might be less; half an inch would be sufficient, even if the weight on a pair of wheels of a carriage were only a ton. The weight which actuated the fan need not be more than 5cwt.; therefore, the small depression of the rails could be multiplied by the lever four times, that is, for half an inch depression it would draw the weight up two inches; so that a train of six carriages and engine would draw the weight up at least thirty inches. This would be quite sufficient to keep the fan continually going where the traffic is equal to that on the Metropolitan Railway. Of course, the amount of draw would have to be regulated by the amount of traffic, and provision would have to be made to prevent breakage in case of overwinding; but these are mere details. General Morin's method of ventilation is certainly an efficient one as to buildings, and we offer this mechanical application of it to underground railways as a simple and cheap mode of clearing their tunnels of poisonous gases.

LANDSCAPE PHOTOGRAPHY.

THE present tide of photographic opinion, in favour of small plates and light apparatus for outdoor work, will evidently result in the supply meeting the demand, for already notice has been given that new "opera-glass" and other small cameras will shortly be introduced by the inventors to the notice of some of the photographic societies. Little pictures so obtained may be readily reproduced on collodion, and of any size, by means of enlarging apparatus. The convenience to the tourist of being able to carry all his apparatus and prepared plates in a little satchel by his side, and the walking-stick legs of his camera in his hand, is too obvious to require proof. Unburdened by bulky apparatus, landscape photography will become a pleasure rather than a task, and will lead to the practice of photography by many who have not sufficient love for the art

Digitized by Google

science to encounter the present difficulties in the way of getting good outdoor views.

A very considerable amount of photographic knowledge and skill is necessary to enable anybody to get uniformly good pictures with certainty by means of dry plates. Ordinary wet-plate photography is out of the question in the field, unless the operator increase the weight and bulk of his apparatus, and the time of taking each picture. When dry plates are used, rapidity of action is necessary to secure natural clouds and the other atmospheric effects, which give life and brilliancy to scenery. Almost the only dry plates which give great rapidity are those prepared by Russell's bromized collodion tannin process, and Sutton's gum process. As Mr. Sutton recommends the former in preference to his own, perhaps because the gum process is somewhat uncertain, the tannin process is the best dry one which can be adopted by photographic adepts. There are other very rapid dry plates on sale in the market, but their method of preparation is kept secret for trade purposes.

There is, however, a very easy process, which we have worked successfully for years, whereby plates can be made to keep in good photographic order for six or twelve hours after preparation; and the manipulations, as a whole, are even simpler than by the ordinary wet method. This is the glycerine process, and it is the wettest method of any, for the plates will not dry for six months or more; they may look dry to the eye after keeping, but the touch will prove they are still damp. As a tourist can easily extemporize a dark room at his place of temporary residence, by blocking up a window with blankets and working by the light of a candle, he has then nothing to do but prepare his plates, wander out for several hours, and take his views, then develope his plates on his return, thus getting pictures having all the delicacy and brilliancy incidental to wet processes, and without trouble.

Here, then, are the formulæ which give the best results as yet attained by this process:—Clean the plate by any of the numerous methods for obtaining a chemically pure surface, then coat it with any good bromo-iodized collodion of commerce, and sensitize in a bath containing 35gr. of pure recrystallized nitrate of silver to the ounce of distilled water. Each 10oz. of this bath should have two drops of acetic acid added, and 1½gr. acetate of soda; it should then be occasionally stirred for a quarter of an hour and filtered, when it will be ready for use. The foregoing treatment is necessary to secure freedom from nitric acid, which would decompose the glycerine preservative. More than the above quantity of acetate of soda should not be added; for, although a small quantity is an improvement, too much spoils the pictures.

The manipulations thus far, it will be noticed, are the same as in the wet process, but the plate has next to be dipped in the preservative bath, directly it is taken from the nitrate bath, and as this is done in an instant, it gives no trouble.

The preservative is mixed as follows:—	
Distilled water	7 oz.
Pure glycerine	2 ,,
Pure honey	1 ,,
Above bath solution (new) . . .	3 ,,
Kaolin	¼ ,,

Bad glycerine sometimes contains lead, and adulterated honey often contains flour, so such samples must be rejected. The above mixture is to be well shaken up in a glass bottle, which should then be exposed to diffused daylight, not sunlight, for two days. It will rapidly blacken, then throw down a muddy deposit, and, if the quantity of kaolin added was sufficient, will leave the upper part of the solution very clear and bright. The upper portion should then be filtered into the preservative bath for use. The plate should be left in the preservative bath for three or four minutes, then it should be placed on end on clean blotting paper in a dark box, for ten or fifteen minutes, to drain. It is then ready for the dark slides.

After it has been exposed in the camera, and brought back to the dark room, it should be at once developed. If it is intended to print upon albumenized paper from the negative, a pyrogallic acid developer should be employed, and the picture will come up to full printing density at once. The intensification ordinarily employed in the wet process is not necessary with the glycerine process. The best restraining acid to use in the pyrogallic developer is the formic, with a trace of citric acid, to prevent solarization when the view taken was brightly lighted by the sun. The rule is to use formic acid alone when the light is bad, and the objects dark, but to employ more and more citric acid in proportion to the brightness of the view. As citric acid is a very powerful restrainer, it should be sparingly used, and it is remarkable what a very small trace of it will correct the tendency of formic acid to produce solarization. If, on the other hand, the negative is intended for printing upon collodion by means of the enlarging camera, iron development must be employed, because pyrogallic acid would give too much density. A highly bromized collodion will be desirable in this case, and citric acid should be used in conjunction with acetic in the developer. Very rapid exposures are necessary with iron development and short-focus lenses.

Any collodion, and any developer, will do with this process, which has the peculiarity of permitting the use of a bromized collodion, containing no iodide at all, although such collodion has long been thought inadmissible in the wet process. In fact, some time ago, Mr. Sutton tried bromized against iodized plates in the wet process, and announced that the bromized plates were utterly worthless. His great mistake was that he treated both plates in the same manner, and the fact is that they require different treatment throughout. In the first place, the bromized collodion should be very highly salted to the extent of not less than ten grains of bromide of cadmium to the ounce. In the second place, plates coated with this collodion should be sensitized for about ten minutes in a sixty grain bath (which treatment would spoil most iodized plates), and then they should be dipped in a weaker bath, to get covered with fluid not too strong for the developer. If this last bath contain also organic matter, like that of the glycerine preservative, the effects are improved. Lastly, a stronger iron developer may be used with wet bromized plates. One great advantage of these plates is the excessive power they possess of resisting solarization, and giving brightly illuminated clouds with an exposure twice as long as would be sufficient to spoil the said clouds if ordinary collodion were employed. Bromized collodion usually works best a month or two after mixing when pyrogallic acid development is intended, but it is not always so when iron development is used; with newly mixed collodion the former often gives a "woolly" picture, void of sharp definition, whilst the latter causes no such defect.

THE ATLANTIC TELEGRAPH.

ON Tuesday evening last, Mr. Cyrus W. Field entertained a select party of friends at the Palace Hotel, Buckingham-gate, to celebrate the fourteenth anniversary of the day on which the New York, Newfoundland, and London Telegraph Company was formed to carry out the grand idea (the value of which we even now do not fully realize) of placing England and America in telegraphic communication with each other. It has often been remarked that had there been no Cyrus Field there would not at the present time have been an Atlantic cable. Knowing the trials and difficulties that gentleman has had to contend with during the past fourteen years, we fully believe that statement, for never since the time of the king whose name he bears has there been a man possessed of so many qualities calculated to achieve success under such trying circumstances. We mean it as no empty compliment when we say that we never found centred in one man such a wonderful ability in managing men's tempers and gaining their affections, nor with such a vast genius and capacity for forming, with equal steadiness and prudence in executing, the work he takes in hand. We are sure that no one more sincerely congratulates Mr. Field than ourselves upon such a glorious termination to the enterprize to which he has devoted the most valuable part of his life.

During the evening telegrams were sent from an instrument placed in the room to various parts of the American continent, and with marvellous rapidity the replies were received. On their arrival each was read aloud by Mr. Field. Heart's Content replied in a few minutes, New York in about an hour, and Washington in about the same time. It may be asked, and justly, too, why it was not possible to connect through to Calcutta and our other Indian possessions, and communicate with friends there with equal rapidity. With humility, if not shame, it must be confessed that, although the Indian and the Atlantic projects were started about the same time, and the latter of these has been so successful, the promoters of the Indian line lost faith after the first failure on the main route, and have been ever since endeavouring to accomplish their object by traversing circuitous routes, through by-lanes and unknown parts. How far they have succeeded the Government blue book on the subject will best explain. But now that the perfect success of the Atlantic cable has been so thoroughly established, we do hope that those gentlemen of whom England may well be proud—who so liberally subscribed their capital for the American cable—will take the matter in hand. They may rest assured that the public will assist them in making the attempt to place England in direct communication with India—adopting what we call the direct route—that is, Falmouth to Gibraltar, Malta, Alexandria, and down the Red Sea to Bombay. The adoption of this route would place us in an independent position as regards all other European and Asiatic powers. It is proved beyond doubt that deep water affords the safest repose for telegraphic cables, and that they can now be manufactured and laid with as great certainty as an engineer would construct a railway, or accomplish any minor operation. There have been leaps in the dark in the management of submarine telegraphy, but all such are to be reckoned as things of the past, and a grave responsibility rests upon those who, to suit some caprice of their own, ignore the lessons which so much dearly-bought experience should teach.

We believe the Atlantic cables are working with greater accuracy and speed than many submarine cables; in fact, if we are rightly informed, even the overland lines are unable to compete with them when their length exceeds a few hundred miles. This is very encouraging for submarine telegraphy, and there is no reason why the time should be far distant when we shall see in the same room two instruments, from one of which a message could be sent, and after performing the circuit of the entire globe, arriving back again to show itself on the other.

FRICTIONAL ELECTRICITY.*

DURING the later years of a life devoted to science and experiment, the late Sir W. S. Harris commenced a work for which

* "A Treatise on Frictional Electricity in Theory and Practice." By SIR WILLIAM SNOW HARRIS, F.R.S. London: Virtue and Co. 1867.

Digitized by Google

materials had been accumulating during many years; the intention was that it should comprise a perfect treatise on frictional electricity, and it was also intended that the book should contain short biographical notices of leading electricians, but before the work could be completed he was seized with his last illness, and died on the 22nd of January, 1867. Before his death he had seen and corrected a large portion of the work, and in that state it is now presented to us, with some additional chapters revised by the editor (Charles Tomlinson, F.R.S.), and by Mr. Harris, amongst which may be noticed two lectures on atmospheric electricity and protection from lightning, subjects in which the author was so essentially at home. The book is prefaced by a biographical notice of the author, full of most interesting matter, and deserving the close attention of all its readers. The following extract shows the late lamented author as a man of peculiar attainments. "He completed the allotted term of man's life: he made some important discoveries in electrical science, laboured long and successfully to introduce into the Royal Navy his system of lightning conductors; was an excellent sailor, an accomplished musician, a lively intellectual companion, a steady friend, and he died honoured and beloved." With the present book before us, and the recollection of his previous works, we cannot but add the title of "successful author" to the numerous catalogue above. We dwell for one moment on the long and hard fight he had before the value of his lightning conductors was fully appreciated, and before they were adopted by the authorities. So tardy were they in adopting a system that has made our vessels so safe at sea, that we actually find that these lightning conductors were introduced into the Russian navy before our own, and that the Emperor presented Harris with several valuables in acknowledgment of the merits of his system.

There are few who have laboured so carefully and successfully in frictional electricity as the author of this book, and to his experiments and elucidation the scientific world is indebted. But the success of his experiments was mainly due to his wonderful skill in the improvement and construction of instruments and apparatus. Of the exactitude of his experiments we cannot seek a higher compliment than that paid by the late Professor Faraday in 1834 (see "Experimental Researches"):—"I have also looked with some anxiety to the results which that indefatigable philosopher Harris has obtained in his investigation of the laws of induction, knowing that they were experimental, and having a full conviction of their exactness." The editor remarks—we make the extract as a pendant to the foregoing—"This care in the selection and improvement of apparatus might seem to an ordinary observer to be often superfluous, but it led to success and to the thorough understanding of the conditions of success, so that the failure of an experiment in Harris's hands became next to impossible." In the present work the chapters on electricity, with their elucidation and experiment, will probably be familiar to many as enlarged reproductions of his earlier works on the same subject, and containing but little that is new, though when we come to examine it we are astonished at the wonderful amount of mechanical skill shown in the construction of the instruments, and the cleverness of the man who conceived so many apparatus.

Although these experiments may be familiar to many, yet there is one chapter in the book that to an experimental electrician is invaluable: we mean that containing a description of "Articles and Processes in Electrical Manipulation." Here we see the results of his labour handed down to us, the means whereby his success was obtained, the care in the selection and use of material so that the best only could be used; even the making of "paste for attaching tinfoil to his jars was a matter of study until the best recipe had been found." The various ways of doing things, as tried by him, are here given with valuable advice. This chapter contains all the articles necessarily required by an experimenter making the whole of the apparatus himself: but at the present time, with the facility of transport and extra skill of labour, there is not that necessity for such a multiplicity of tools and materials as in the days when Harris experimented: there appears in the list nothing left out. The success of electrical experiments depends greatly upon the proper insulation of the materials used; many have, of course, to be varnished to render them insulating: into varnishes, pastes, and amalgams for machines, the author appears to have penetrated so far as to have exhausted the subject. We are presented here with as many as thirty-nine formulæ for these various preparations, some required for one purpose, some for another, but all most useful, many supplying a want hitherto felt in the laboratory of a good and proper varnish for certain purposes. For this chapter on electrical manipulation alone we would recommend this book as a necessary part of the electrician's library. What must we say, then, when there is so much valuable matter besides?

Parliamentary Notes.

THE reconstruction of the Ministry caused a temporary cessation of public business, but now that matters have been adjusted both Houses have gone to work again with a will. They commenced proceedings yesterday week, when the first topic of discussion was, of course, the Ministerial changes. After the members had congratulated and condoled with each other as occasion required, they did an unpardonably stupid thing, in throwing out the Metropolitan Tramways Bill. To Mr. H. Lewis is due the discredit of proposing the bill be read that day six months, on the ground that it was a "fishing" bill. He also urged in favour of his amendment that two bills of the same character had been thrown out in past years! So, Mr. Lewis, it follows that a third, and perhaps any unlimited number, are to be added to the list? All we can say is, we are sorry the bill has been thrown out. It ought certainly to have had a chance for life in committee. There was reason and common sense in Mr. Seely's remarks in support of the bill. He very properly observed that the tramways which were proposed to be laid down would not in any way interfere with the ordinary traffic of the streets. He could not see that the ratepayers would be injured much by breaking up the streets for the laying down of the tramways, for the reason that the company would be compelled to keep in repair 16ft. in width of the road in the case of a double tramway, and 7ft. 6in. in the case of a single line. It would be unfair in the House to refuse the second reading of this bill within twelve months of the time when they passed an Act to regulate the street traffic of the metropolis. He did not think the rails would throw down horses or carriages, for the reason that they would be only 2in. wide, and the horses' hoofs would grasp a part of the roadway as well as the rail. The advantage to the traffic would be great, inasmuch as the cars would carry twice as many passengers as could be conveyed by ordinary omnibuses. That the parish authorities did not regard the bill unfavourably was clear, from the fact that out of the whole fourteen parishes only two really opposed the proposal. Mr. Seely concluded by urging that the tramways experience in America was an argument in favour of their adoption in this country. It was all, however, of no avail, and although Mr. T. Hughes supported the bill, the amendment was ultimately agreed to without a division. We shall, however, hope to see the bill brought forward again next session, and trust the public will not rest until they obtain legislative sanction to a system which will render the locomotion of the metropolis cheaper, less dangerous, and more expeditious than it is at present.

In the House of Lords, on Friday, the Earl of Cardigan presented a petition from Henry Needham Scrope Shrapnel, late of the 3rd Dragoon Guards, praying that some national reward might be made to him in consideration of the services rendered to the country by the use of the shells invented by his late father. As a proof of the value which the Government attached to this invention he might observe that millions of the Shrapnel shells were used by them during the Crimean war. The noble and gallant earl said he would move that the petition be referred to a select committee.

This rather cool request was replied to by the Earl of Longford, who justly observed that on the part of the War Department he should object to a reference of the petition to a select committee. He could not hold out any encouragement to the petitioner. It was true that the invention of the Shrapnel shell was a most valuable invention. For many years it had been in constant use in the service. But the inventor received a special pension of £1,200 a year for twenty-eight years. He further received a royalty of more than £10,000 from the East India Company. The petitioner's claims had been frequently brought forward, but they had been rejected. Sir Cornewall Lewis, whose judgment was entitled to great respect, decided that no further claim could be admitted, and Sir John Pakington was of the same opinion, and we are of the same opinion too.

Monday evening was a busy time in both houses. In the Lords, the Duke of Somerset, in moving for a return of the number of tons of iron ballast sold from the Royal dockyards since January, 1867, the amount of money received for the iron, and paid into the Treasury, said various charges of waste and mismanagement had been made against the Admiralty which it was difficult to bring to any precise test of facts. But, last year, an hon. member of the other House of Parliament stated that iron ballast to the value of £100,000 had been employed for the paving of the dockyard, and that he could produce a person who would buy it for that sum. That offer was accepted by the Admiralty, and he (the Duke of Somerset), on moving for this return, wished to know what had been actually received for this sale of iron ballast by the Admiralty.

Although the motion was agreed to, and in due course his Grace will receive a reply, the answer was virtually given the same evening in the other House, where Mr. Baxter asked the First Lord of the Admiralty whether any part of the pig iron ballast, laid down or stored in the dockyards, and sales of which were estimated to produce £100,000 during the present financial year as a naval "extra receipt," had been sold; and, if so, how much and at what price per ton; and, how many tons were still stored or laid down in the dockyards.

Mr. Corry said the Admiralty had been unremitting in their endeavours to realize the anticipations entertained last year as to the amount to be realized by the sale of the pig iron in the dockyards, but very little had been sold. In short the Admiralty had received no offers that could be entertained except for very small quantities for experimental purposes, and the amount actually paid into the Exchequer on account of sales was £63—for ten tons of the iron!! He would reserve further explanations until a more convenient season. Mr. Seely's pigs would seem to be a drug in the market.

It is to be regretted that we are improving the health of the metropolis at the expense of the navigation of our river. Such, however, is a fact; our sewage is accumulating in the Thames, and Lord E. Cecil has had to ask the Secretary of State for the Home Department whether it was true that complaints had been made to the Home Office by the Thames Conservators of the navigation of the river having become obstructed by the accumulation of sewage at Barking and Crossness; and, if so, what course he proposed to take in the matter.

Mr. Hardy said it was true complaints had been made by the Thames Conservators, and, in consequence, he saw the chairman of the Board of Works, and all he could do was to make a suggestion that an arbitrator should be appointed to decide upon the matter. It appeared, however, that the Metropolitan Board of Works were advised by their counsel that arbitration was not the proper course to adopt, and therefore he (Mr. Hardy) feared that the matter must be decided by a court of law. This is rather an unpleasant state of affairs for all parties.

We have before now called the attention of our readers to the alleged instability of our new fortifications. This matter came on in the form of question and answer, Colonel Sykes leading off

Digitized by Google

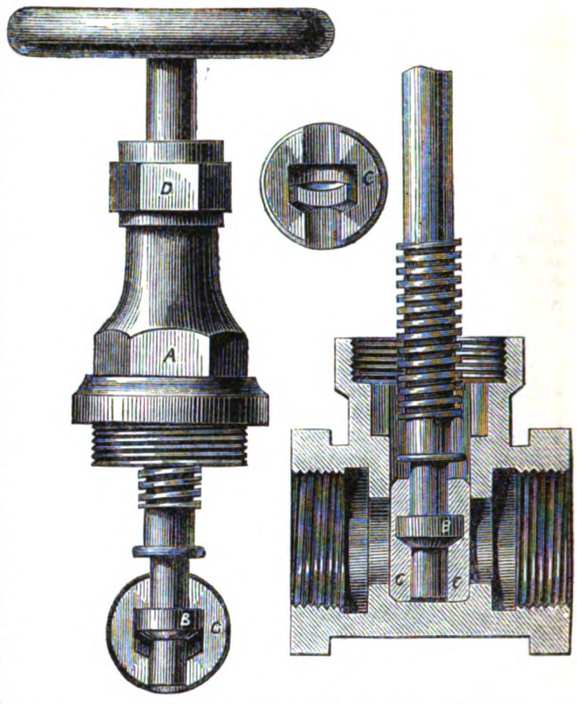
by asking the Secretary of State for War what truth there was in a recent statement in the public prints, that one of the projected fortifications at Chatham had sunk into the mud, or that the foundations had given way, and that some of the new fortifications elsewhere had shown signs of instability. And whether, considering the opinion expressed by the distinguished civil engineer, Mr. Thomas Hawksley, on August 26, 1866, that "many endeavours have been made, and much money (reckoned by millions) has been expended, I will not say wastefully or unworthily, but certainly uselessly, in endeavours to secure our coasts against the attacks of a foreign enemy;" and whether, considering the statement, under the head "Naval and Military Intelligence," in the "Times" of November 3, 1866, that we "have certainly, as a rule, been unfortunate in our military engineering, and especially in carrying out the plans for the defence of our coast line; that some forts have been built on swampy land, so unstable and treacherous that keep and magazine have cracked through, and their earthen ramparts have slid from their base;" before a further application for money was made to the House, the Secretary of State for War would lay upon the table a report in detail of the present condition of the fortifications enumerated in the Parliamentary Return, No. 157, of March, 1867; and in default of such report whether he would advise her Majesty to appoint a commission of military and civil engineers and members of the House to examine and report on the present condition of the fortifications, and whether any of them could be dispensed with.

From the reply it would seem that much more has been made of the matter than circumstances justify. Sir J. Pakington said that two of the forts near Chatham, having been built on marshy ground, had in some degree subsided, but nothing would prevent the forts being satisfactorily completed. As to whether some of the new forts had shown signs of instability, he might say that at a fort at Warrington, in consequence of a change in the soil, part of the retaining wall had shown some signs of weakness, but nothing would prevent it being repaired satisfactorily. The remainder of the question appeared to be rather in the nature of an argument than an inquiry. He thought there was some degree of inconvenience in the practice of introducing long recitals into questions containing very severe attacks upon the public departments, proceeding from persons who had expressed their views without the responsibility proceeding from authority. He had great respect for Mr. Hawksley, but he could not consent to accept his authority as conclusive, compared with that of naval and military men of the highest standing, upon whose advice the Government of Lord Palmerston determined to carry on the fortifications. With regard to the extract from the "Times," the statements contained in it were far beyond the facts. As he considered the questions of the hon. and gallant member, coupled with the extracts he had given, were calculated to create anxiety, he had no objection to furnish a report upon the present condition of the fortifications. This course will doubtless give satisfaction to all, and will set the question at rest. No—not all perhaps—for the "Times" correspondent yesterday uttered a vehement protest against the reply given by the Secretary of State for War, which, he says, is opposed to the truth. The correspondent does not like his veracity impugned, and depicts a very lamentable state of things. While the promised report is in course of preparation, we will endeavour to go and look for ourselves.

LONDON ASSOCIATION OF FOREMEN ENGINEERS.

THE ordinary monthly meeting of members took place on Saturday, the 7th inst., Mr. Joseph Newton in the chair. After the election of several new members, and the nomination of others, Mr. David Walker read a paper on the shrinkage of iron castings. The subject was treated in a thoroughly practical and scientific manner, and was made highly interesting to the associated foremen. We trust that at a future time we may have an opportunity of imparting some of the information contained in the paper to our readers. At present, it can only be said that much research and careful observation of foundry practice, on the part of its author, was made abundantly apparent by its contents. In the discussion which followed, Messrs. Hedley, Keyte, Muir, Vinicombe, Clark, Briggs, and the chairman, took a prominent part. The proceedings terminated with a vote of thanks to Mr. Walker.

PEET'S PATENT VALVE.



THE accompanying illustration represents a valve patented by Mr. S. J. Peet, of New York, which appears to have been giving great satisfaction, both on account of the simplicity of its construction, and the ease with which it may be repaired. From the engraving, representing the valve in section, it will be seen that the two discs serving to close the valve are raised or depressed by means of the hand wheel and upright stem B. These discs are suspended on the stem by its collar engaging with the semi-circular recesses on their inner faces, and prevented from separating from the stem by the walls of the passage in which they move. The lower face of the collar B, and the lower portion of the recesses in the discs are made slightly conical, so that after the discs have reached the bottom, any further pressure on them by the screw of the stem forces them apart and firmly against the walls of the valve, thoroughly closing the apertures of the pipe. The conical collar, therefore, acts as a wedge aided by the pressure of the screw. It will be seen that both sides of the pipe are closed by this means, making this a back pressure valve, as well as a direct acting gate. When the discs are raised, a free passage, without change of direction, is made through the valve for the steam, water, or gas, of the full size of the pipe. The stem is packed in the usual manner by the screw gland D.

MEE'S HOSE COUPLING.

THE intention of the inventor in this device is to make a tight coupling without the aid of a washer, or of the loose setting-up ring, or of any device for forcing the two parts of the coupling together in the line of their axes, in order to form a water-tight joint. This coupling does not depend upon the mechanical force exerted to close the joint, but the pressure of the water itself makes the joint tight.

Fig. 1 represents one end of the coupling, formed where the leather or rubber is attached precisely like any other, but otherwise differing. It has a projecting ring, A, around the barrel part, a portion of which ring is cut away to receive the hooks or

FIG. 1.

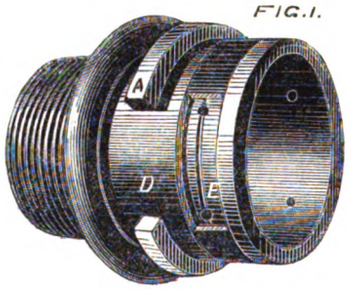


FIG. 2.

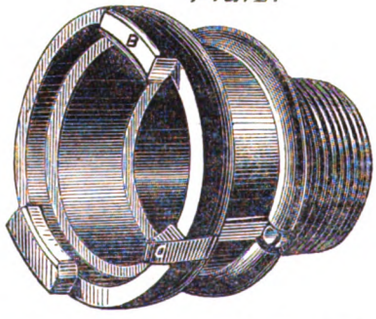

snugs B, fig. 2, which pass by the ring A, and, by a slight turn of one or the other part, securely lock the two lengths of hose or the two parts of the couplings together. This partial turning is, of itself, a sufficient lock to the parts, but to render assurance doubly sure, a spring catch C is introduced which springs into the space D, fig. 1, between the parts of the ring A, and prevents the parts from unlocking, unless force is used to raise it from its seat. Near the end of fig. 1 is turned an annular groove in which is seated a rubber ring, or a ring of some elastic substance to act as a packing. It will be noticed that a row of small holes is bored through from this annular recess to the inside of the coupling, the holes communicating on the outside with one another by a channel E. Through these holes the water inside the hose or coupling finds its way, and its pressure forces out the elastic ring against the inner surface of the section shown in fig. 2, making a perfectly water-tight joint. The "Scientific American," from which paper we gather particulars, states that this coupling was patented in the States by Mr. B. Mee, and is now being largely made by Messrs. Mee and Jackson, of Troy, N.Y.

LITHOLOGY OF THE BRITISH ISLES.

M. DELESSE has just laid before the Academy of Sciences a large map of the various beds of rocks constituting the bottom of the British seas. This bottom chiefly consists of sand, slime, more or less mixed with the latter, and different stones. The latter, already consolidated, are anterior to the present period, and do not receive deposits. They stretch far into the sea from the north-west coasts of Scotland, the Orkneys, and the Hebrides; they also exist at the mouth of the Shannon and the north-west coast of Ireland. In the British Channel they mark the junction of Cornwall with Brittany; they also mark those of the Isle of Wight and Portland with the Continent. To the east of England these stony formations are hardly to be met with elsewhere than at the mouth of the Tees and in the direction of Cape Flamborough. They generally form the bottom of the straits and friths that are washed by rapid currents. Shifting deposits are large in proportion to the rapidity of the waters that have borne them. The most important consist of sand, which occupies immense space on the Atlantic coast, the British Channel, and the German Sea. Gravel deposits, which are not extensive, are to be found on the western coasts, in the Bristol Channel, between the Land's End and the Scilly Islands, and south of Cork. Flint shingle borders the white cliffs of England, but it is also met with in the German Sea in the latitude of the Orkneys. Slimy deposits are peculiar to the mouth of the Thames, Southampton Water, Torbay, and the Irish Coast of St. George's Channel. At various points of the coasts there are marine deposits of molluscs and shell-fish. They are somewhat rare on the eastern coast of England and the southern one of Ireland, but very frequent in the Irish Sea, and all round Scotland, especially in the Minsh, and between the Orkneys and Moray Frith.

SOIREE OF THE ROYAL SOCIETY.

ON Saturday evening last, General Sabine, R.A., as President of the Royal Society, gave the first of this year's soirees. These soirées are usually looked forward to with great interest, by reason of the novelty of many of the things exhibited; but the chief interest appeared to be called forth by the advent of the Prince of Wales, who honoured the President by his company. The Prince was conducted by the President through the various rooms, and appeared to be greatly interested by all the various exhibits that were explained to him. From none did he appear to receive greater gratification than from the explanation, by Professor Tyndall, of Faraday's beautiful experiment of the magnotization of light. This experiment was considerably heightened in interest by reason of the electromagnet and other parts being those actually used by Faraday. A polarized ray passing through an opening in the poles of a very powerful electromagnet, was, by the action of the magnet, when excited, thrown upon a screen, and other experiments were made with the view of showing the action of magnetism on light, the effect being shown immediately the magnet was excited, ceasing so soon as the current ceased.

The semaphore proposed for exhibiting telegraphic intelligence of storms, shown by the committee of the Meteorological Office, excited a great deal of attention. A map is shown dividing the country into eight districts, which are lettered and represented on a circle fixed at the upper part of a post. Moving from the centre of this circle are two arms—one red, pointing to the letters representing the direction of the wind; and the other shorter and painted green, to mark the district where the wind is blowing. On the post itself is shown a number representing the force of the wind which is indicated. A black ball shows whether the wind is within the circle marked on the map. Our space at present precludes us from going further into this interesting subject. The Meteorological Committee also exhibited three interesting instruments, termed the anemograph, thermograph, and barograph, to be used at the observing stations—the first to indicate the force and direction of the wind, consisted of a series of hemispherical cups, rotating horizontally on the top of a post. These, in connection with a train of wheels so acted on a spiral metallic pencil, recorded the force on a cylinder properly prepared, and kept moving by a series of clockwork, the direction being indicated in a similar manner, the motion being communicated by a small windmill, kept in the same direction as the wind by means of an arrow. The thermograph and barograph were instruments for keeping a constant record of the state of the thermometer and barometer photographically, so that the curve shown by the different variations of temperature, and of the pressure of the air, should be periodically and faithfully recorded.

Mr. Ladd showed his improved form of dynamo-magnetic machine, which differed from that exhibited at the soirée of last year, in having the two armatures working on one axle. This is a decided improvement, allowing similar results to be produced with less mechanical force. Some vacuum tubes were shown by the electricity obtained from this machine.

Mr. Latimer Clark's potentimeter, for subdividing the tension of a single cell into 10,000 equal parts, met with a great deal of attention, as did also Sir William Thomson's rotatory induction machine for statical electricity. Mr. Knight, of the South-Eastern, exhibited a design for a cab lamp, showing whether the cab is engaged or on call; also his plan of adopting railway signals for the protection of street crossings. It appears to us that the sudden raising and lowering of semaphore arms in a crowded thoroughfare would, by frightening high-spirited horses, tend to do harm. Mr. C. V. Walker exhibited his system of passenger communication, as used on the South-Eastern. We must not forget to mention the pneumatic telegraph signals, exhibited by Mr. Weir, for ships, mines, railways, &c. They were shown as being in operation on board ship, and appeared to work with the greatest ease and regularity. He also exhibited an apparatus for firing guns from aloft or from any position.

Amongst other articles which we have no space to describe we noticed the extraction of occluded hydrogen from palladium, and dialytic separation of hydrogen from coal gas, by the Master of the Mint; patent gas economizer, smokeless fuel for steam boilers, and Benson's patent breech-loader, by Mr. F. N. Gisborne; electrical apparatus and chains, by Mr. Pulvermacher; models of Jerusalem, by Colonel James.

A working model was also shown by Captain John Moody of a floating battery. There were other objects of interest, as works of art, &c., which, with other things we cannot find space to mention, met with a great deal of attention. The rooms were crowded throughout the evening, and the soirée, although not possessing any one great distinguishing feature, was as successful as these delightful reunions deserve to be.

IMPROVED BAR-TESTING MACHINE, AND CALLIPERS.*

By MR. JOHN PAGE.

THIS simple and ingenious machine—designed by my friend Mr. H. J. King, who represents here the contractors of the Calcutta Waterworks—for testing the strength of cast-iron bars, has been made by Messrs. D. Y. Stewart and Company, of this city, and used by them for subjecting the iron used to the tests now always required by engineers of waterworks.

A simple and cheap testing machine, that will give, to a pound, the breaking weight of a cast-iron bar an inch square, is much called for now in Glasgow, on account of the pretty general use of pig iron from Middlesborough; and we hope, ere long, to see one in every pipe foundry in town. Messrs. Edington and Son have a powerful testing machine, but it is too expensive for the ordinary use of a pipe foundry. No specifications are now issued by engineers of waterworks, without a clause binding the manufacturers to use iron of such a quality or strength that, when cast into a bar of certain dimensions, and placed on supports certain distances apart, it shall be capable of bearing a given weight, applied at the centre, before fracture; and, whatever difference of opinion may exist as to the test the iron used on different classes of work should be subjected to, it is certain the majority of engineers agree that this test is a valuable one. Although, from the great variations often found to exist in two bars cast from the same ladle, in the same box, and under apparently precisely similar circumstances, it seems ridiculous to reject a whole day's work from such a result, yet, when a series of experiments are made, and an average taken of the whole, daily fluctuations are obliterated, and a fair opinion may be formed of a certain mixture.

Fig. 1 is an elevation, and fig. 2 is a section of the testing machine. On the main spindle S, on which weight T is keyed, there are two threads cut; one near the centre, on which the hand-wheel M runs, has six threads to the inch, and the other, near the top of the spindle, has five threads to the inch,; on this thread the disc C works for registering the deflection. It will be noticed that the face of the disc C is shown in contact with that of the brass bush B, through which the top of the spindle passes, and that the hand wheel M is against the face on which it works when the large weight is being lowered on the bar.

It will now be readily understood that in the position shown, if the hand wheel M is turned round one revolution from left to right (it being a right hand thread), the spindle will be lowered one-sixth of an inch, and, in the meantime, if the disc C had no motion communicated to it, there would now be one-sixth of an inch of space between the face of the disc and the face of the bush; but if the hand wheel and the disc C are connected together in such a manner that when the one turns the other moves as well, but with freedom to slip if an obstacle present itself, to stop such a motion, the disc will always be kept against the face of the bush; for, while the spindle is sinking one-sixth of an inch by one turn of the wheel, the tendency of the disc is to rise one-fifth of an inch, which it would do were it not prevented by coming against the face of the bush. This connection is practically made by the tube J, the lower portion of which fits into the hand wheel, and on the upper, above the collar H, a short brass tube E is fitted, having a slit cut a part of the way down, which, when sprung over the smaller portion of the disc, forms a spring clip possessing sufficient friction to move it round, but at the same time allowing it to slip easily when it comes in contact with the face of the bush; this, then, will always give the deflection correctly proportioned to the fall of the spindle, and it will be perfectly independent of the position of the hand wheel with regard to the face N, which is variable, as will be seen afterwards, in lifting the upper weight. The amount of deflection is read off on the circumference of the disc C, which is formed of a sliding brass ring, graduated into two equal parts of 100 divisions each, every division representing a fall in the spindle, or a deflection in the bar of 1-1000th of an inch, and at each semi-revolution of the ring a stud in it turns the small ratchet wheel above it round a tooth which completes the registration of the deflection to three decimal places.

After the bar, which is to be tested, has been placed in its proper position, and the V-piece in the centre of the spindle just brought into contact with it, the disc C is brought up by hand against the face of the bush B, and the graduated ring turned round till it is brought up to the zero point, the hand wheel is then turned round, and the whole of the lower weight is allowed to come on the bar T. This weight, including spindle wheel and all other connections, weighs 700lb. (but can easily be made up to any dead-weight required), is allowed to come upon the bar. The 700lb. will seldom be found sufficient to cause fracture, and it then becomes necessary to bring additional weight into action. This is done by continuing to turn the hand wheel M till the three little steel rollers, which work in slots in the loose ring L, come into contact with the under side of the weight K, which, it will be observed, is supported by two spiral springs fastened to the angle irons D D at the side of the frame, and if this motion be continued, and the bar be strong enough, the whole of the weight previously borne by the springs will be transmitted to the bar, giving a total testing weight of 950lb., as the small weight K weighs 250lb. this range being found sufficient, with very few exceptions, for all tests required.

The proportion of the upper weight which is brought into service in breaking the bar is read off upon the scale G by the pointer F, the deflection of a spring is always proportional to the amount of weight it has to bear. The actions of the springs and graduations of the scale were verified by having two pulleys fitted into the frame A, and two ropes attached to the weight by the pins I I passed over them, and dead-weights O O hung on the other side, which, with a knowledge of the friction of the pulleys and the rope, easily determined beforehand, gives the best possible check to the scale; and it is very satisfactory to find that when this test is applied it accords exactly with previous anticipation. It is only necessary, then, to determine with accuracy the two extremes of the scale, at the one end by bringing the rollers just up to the weight as it hangs suspended by the springs, and at the other by slackening back the lock nuts under the angle irons, and screwing up the weight till it is seen there is no weight on the springs. If we now suppose the bar to break at any point, the spindle with all its connections will fall on the india-rubber washer V on the top of the bottom bush, and the deflections with which the bar broke at will remain recorded on the deflection disc, while the weight will be given by the pointer on the scale, so that both weight and deflection can be read at leisure after the bar is broken.

The short end of the pointer F is provided with a slot into which is fitted a pin, which, resting on the collar on the top of the tube, moves up with the weight. This provision being made to allow of an adjustment to suit any variations in the strengths of the springs, which will, no doubt, become weaker in time, although there is very little wear upon them in consequence of their being relieved of all strain except when the bars are being broken.

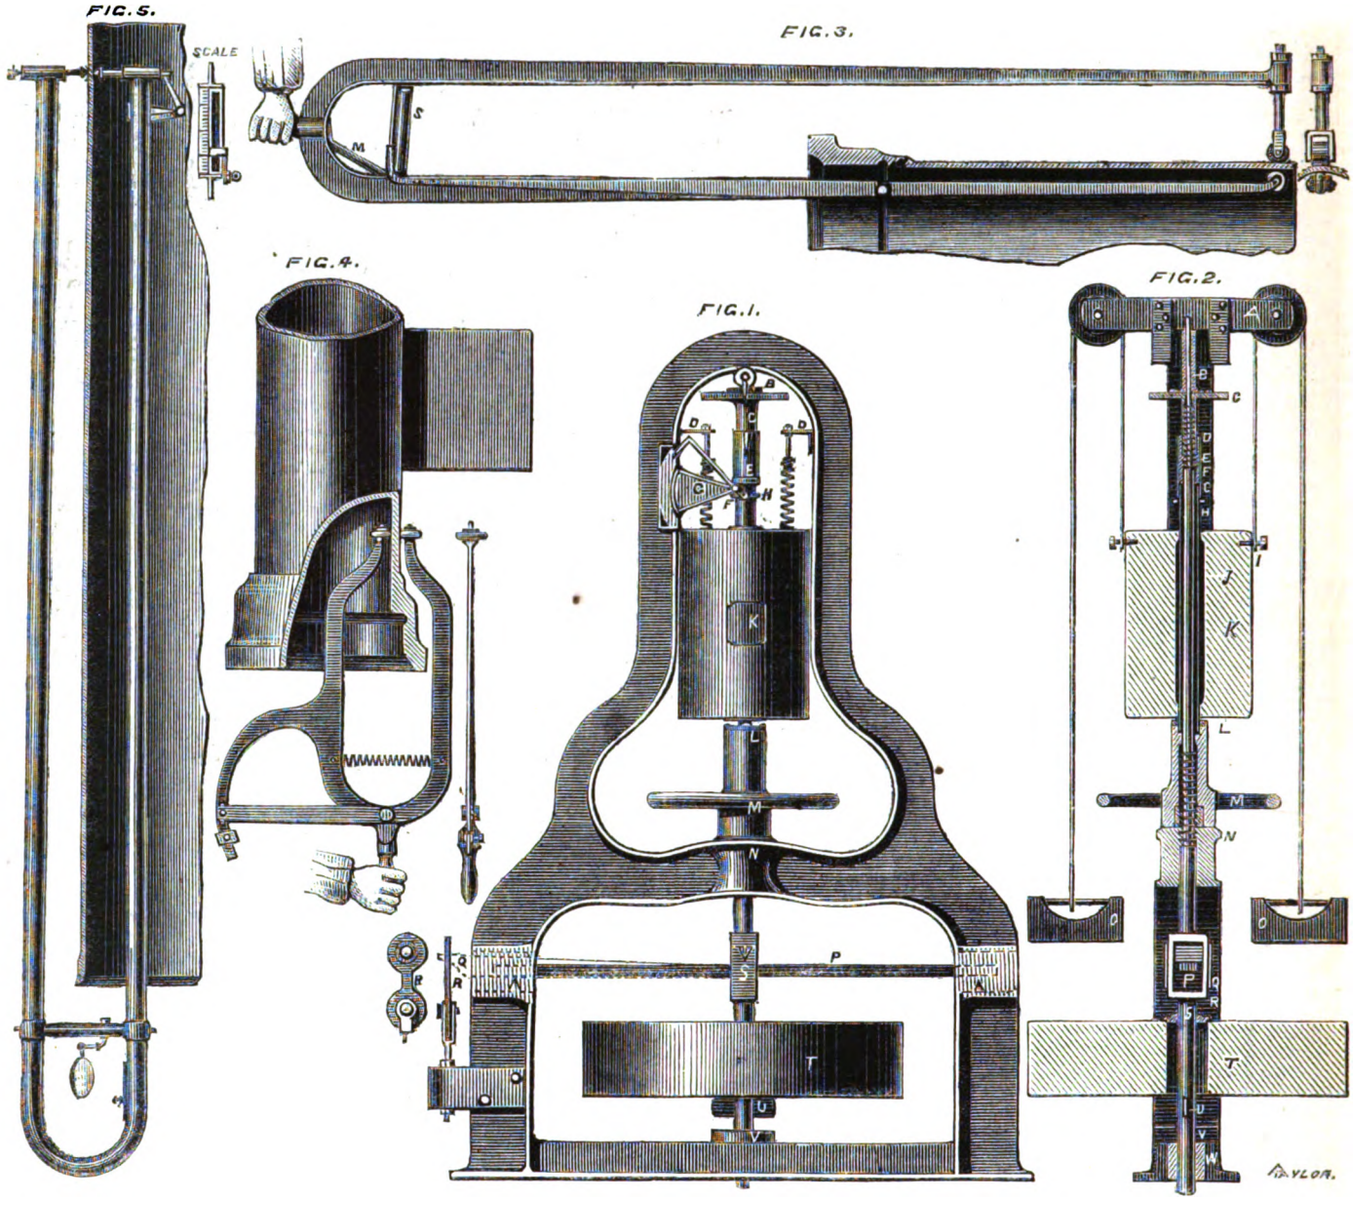
It might be suggested that small lead weights picked up one after the other by the hand wheel as it rose would act with more certainty than springs, but a little consideration will show that an error may be introduced in the breaking weight equal to the amount of one of these dead weights. For instance, when an additional weight of 250lb. is required, this could be made up with ten 25lb. weights, which would be quite as many as could be used with convenience; but here you might introduce an error of 25lb., for it might possibly be the last lb. of a weight which broke the bar, but it would not get credit for the 24lb. which it stood without breaking if the weights are not counted until they are clear of all support, and if this condition is complied with, it is easy to see that the weight which really breaks the bar is never lifted at all. Whereas, on the contrary, if the record is taken as soon as the surfaces of the two weights come into contact, the bars will be represented on the average as standing 12½lb. higher

* Read before the Institute of Engineers in Scotland.

Digitized by Google

BAR TESTING MACHINE AND CALLIPERS.

BY MR. H. J. KING.



than they really did. This difference of reading with the same weights and the same machine, making the average of bars read the one way higher than the other by the amount of the least weight used; but, independently of this, the gradual application of the weight, such as is given by the relief of the springs, must be preferable.

The application of two spiral springs which might be put into tension by the hand wheel as it rose would perhaps be a simpler arrangement than the present one, but the objection to springs used in this way is, that they become weaker in time and there is no way of discovering an error, whereas a dead weight suspended forms an unerring check which detects any variation at once, and enables a correction to be made. It may be mentioned that the little downward thrust produced by the pressure of the deflection disc against the brass bush, but which is very light, is considered to counterbalance the little friction which must exist in the spindle working in the top and bottom bushes.

The machine can also be used for testing the tensile strength of metals, by placing a steel lever on the V-piece and making it the fulcrum; the short end of the lever passing through the frame, and the long one coming under the knife edge in the centre of the spindle. The link to be tested is fastened at the lower end by the pin slipped through the joint connected with the frame, and the other is slipped over the end of the lever. This arrangement being completed sufficient weight is applied in the ordinary way to break it. With the present lever in use the minimum weight that can be applied is 2,100lb., and the maximum 5,700lb. This variation being effected by shifting the centre of the lever on the fulcrum, making the ratio of the long and short ends 3ft. and 6ft. to 1 respectively.

The callipers have been expressly designed for testing the thickness of pipes. The long one, fig. 3, is adapted to measure the thickness of pipe 4ft. 6in. in from the end, and the shorter one, fig. 4, gives the maximum and the minimum thickness at the spigot ends. Upon the upper leg of the long callipers, fig. 3, and at the extreme end, a stud or pin is fitted, carrying a roller, which runs upon the top of the pipe; and on this stud a thread is cut, to allow of adjustment, by means of the nuts at the top and bottom of the boss through which it passes. Upon the lower leg, which is about two-thirds the length of the upper one, a lever works upon a stud at the end. The shorter end of the lever is provided with a small roller, which is kept against the inside of the pipe by means of the longer end, by being of greater weight; and this end records the thickness of the pipe upon the vertical scale S which is fitted between the two sides of the instrument, and likewise performs the office of a stay. In order to read this scale horizontally—which, in practice, is found necessary, to avoid stooping, when testing small pipes, a plate-glass mirror M is fastened to the frame, at an angle of about 45deg., which, reflecting the vertical scale, enables it to be easily read by anybody standing above it.

It is hardly necessary to state that these callipers can only be used for trying the thickness at the top of the pipe; but, practically, there is little advantage in this; as the light side always comes to the top, if a pipe is rolled on a level surface, and it can easily be turned round and tested again, if desired. The reason why the callipers give the thickness of the pipe only on the top is, that there is an error occasioned by its springing, which can only be corrected when held vertically. As long as it is held so, the error is constant. It can be taken into account, and the instrument adjusted accordingly; and if the person using it holds the handle at the extreme end, resting the large roller on the top of the pipe, and allowing the roller at the end of the lever to come against the inside of the pipe, it may be relied upon as giving an uniform result. The scale is divided by passing the rollers over a carefully-prepared iron scale, which is held horizontally in a vice; and the adjustment is easily done at the stud, on comparing the reading on the scale of the callipers with that on the iron scale, as the roller passes over the latter.

The other long pair of callipers—fig. 5—is a modification of the callipers first made by Mr. King. It is made of a wrought-iron tube, in

Digitized by Google

which is carried the rod connecting the bell-crank with the scale, that records the thickness of the pipe. The connecting-rod is thus protected from injury, instead of being exposed, as in the first callipers made by Mr. King; and as the callipers are round, no handles are required, as in fig. 3—a magnifying glass is used to read the scale.

The small pair of callipers, fig. 4, are found to be useful in giving, at a glance, the minimum thickness at the end of a pipe—to try which they are opened by hand and slipped in it, the two small steel rollers being kept up by the spiral spring against the inside and outside surfaces. They are then run completely round the pipe, and, previous to being taken off, an examination is made of the slide on the scale, which is connected with one leg of the callipers, and which is pushed back by the arm on the other, as the surfaces of the two wheels, kept up by the spiral spring, come nearer together, until the minimum thickness is reached, the slide then remaining till it is read off. When put on another pipe, the slide is pushed up by hand to the arm, and the process repeated as before. The ordinary mode of testing a pipe for thickness is to try it with the long callipers at the centre and spigot end, and afterwards run the small pair round the socket end, which shows the minimum thickness there; and, if a pipe stand these tests, it may be considered uniform throughout.

SECURING WOOD TO IRON IN COMPOSITE SHIPS.

WHEN ordinary screw bolts and nuts are used to fasten a wooden planking to an iron frame it is difficult to obtain sound and secure work, because the holes punched in the iron frame are taper, and therefore the bolt touches the frame only on a line of inappreciable width, even assuming that the hole is punched exactly of the proper size; hence the rigidity of the structure depends mainly on the nip of the nut against the frame. This question has been practically dealt with in the patent before us by Mr. James Laing, of Deptford-yard, Sunderland. He uses nuts having a thin and somewhat taper ferrule formed on them on the under side, and this, as the nut is screwed on, enters the upper end of the taper hole, and when the nut is screwed home becomes jammed and ground into it so as effectually to fill the taper hole around the bolt. Such bolts and nuts are applicable in most cases in which it is desired to make an attachment to a metal frame having holes punched in it to receive bolts.

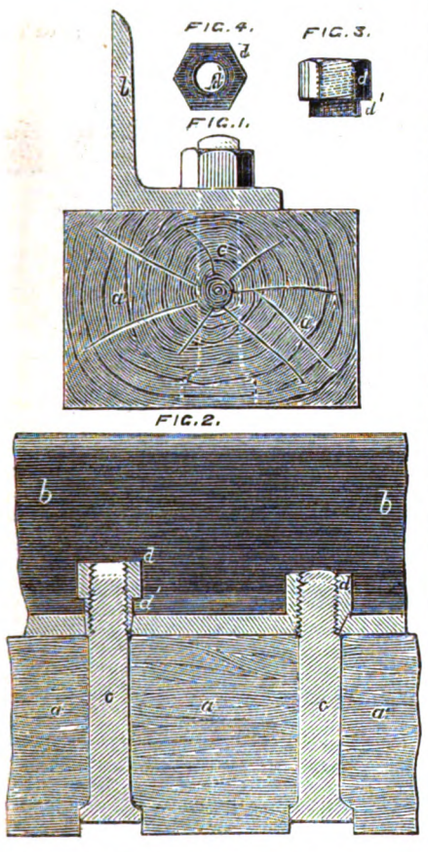


Fig. 1 of our engraving is a transverse section of a wooden plank secured to an iron frame by bolts and nuts, the nuts having ferrules upon them to fill the taper holes punched in the frames; fig. 2 is a longitudinal section; *a* is the wooden plank; *b*, the iron frame; *c c*, the screw bolts; and *d d*, the nuts which the bolts receive upon them. A side view of one of the nuts is shown at fig. 3, and an under side view at fig. 4. *d*¹ is the ferrule formed on the nut; its length should be nearly equal to the thickness of the frame *b*, but less rather than greater; it should be slightly taper, and of a size just to enter the mouth of the taper-punched hole in the frame, as is shown at the left-hand side of fig. 2; then as the nut is screwed home the ferrule *d*¹ becomes ground to fit and fill the hole in the frame, as is shown at the right-hand side of fig. 2, and in this way the working of the bolt in the bolt hole is effectually prevented. We are not yet able to record the practical application of Mr. Laing's system to any vessel, as the invention is a very recent one. It has, however, been highly and deservedly approved of by Lloyd's Committee for Shipping and their surveyors, and the invention is one of such manifest utility that we may safely predict its speedy and general adoption.

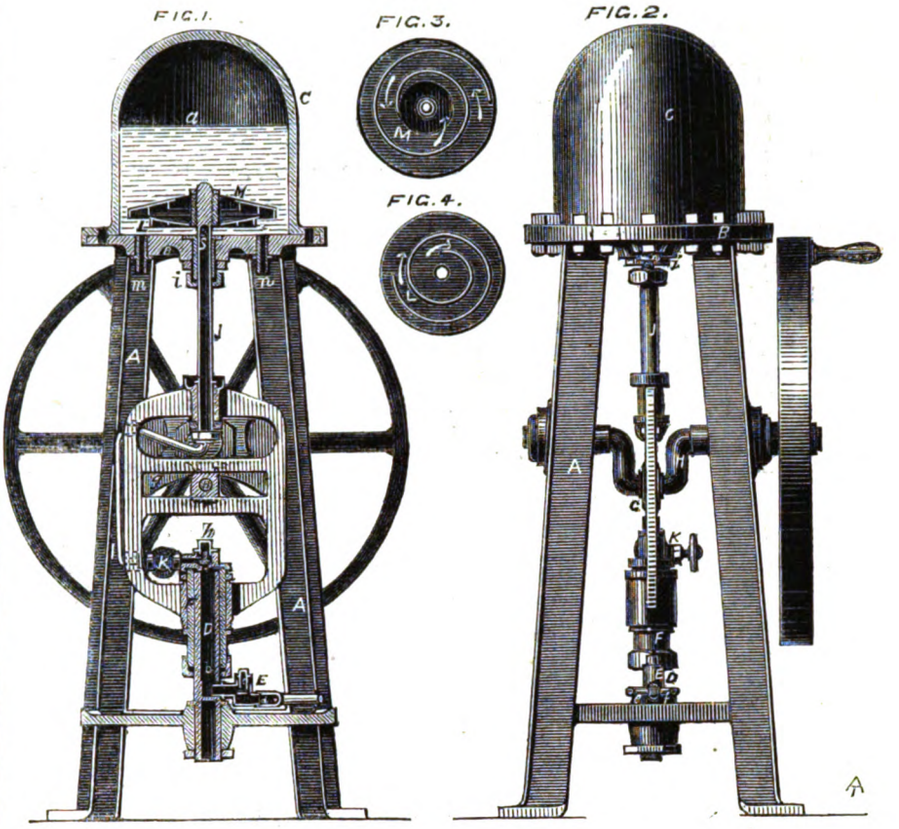
MACHINE FOR MANUFACTURING ÆRATED WATERS.

BY MR. J. MATTHEWS.



MACHINE FOR MANUFACTURING ÆRATED WATERS.

IN the above engraving we show a machine for manufacturing soda water and other aerated liquids, which possesses simplicity, and is steady in work. It has lately been patented in England by Mr. J. Matthews, of New York. In this apparatus the pump feed and agitator to the condenser are connected together without the application of joints to the latter above the average water level. The feed and agitator are operated through the base of the condenser, and the discharge or feed pipe passes from the pump into the condenser and imparts to it a reciprocating action by or with the pump. Thus the pressure of gas or liquid in the condenser is made to assist the pump in its discharging or feeding stroke to the condenser by acting upon the exposed end of the discharge pipe. In combination with the reservoir or condenser there is a pump for charging and keeping up the supply to the latter. The constituent parts of this pump are a stationary hollow plunger and a reciprocating cylinder with suitable inlet and delivery valves, and an upper reciprocating discharge or feed pipe. By this arrangement great simplicity of working parts is effected and a steady guiding action secured to the pump. On the end of the discharge pipe which projects into the condenser from below, one or more volutes, or their equivalents are placed so as (in the reciprocating action of the pump) to catch and distribute the gas in the water, and to agitate the latter within the condenser for the purpose of effecting a thorough mixing of the gas and water.

Fig. 1 represents a sectional elevation of this apparatus as applied to the manufacture of soda water; fig. 2 is an outside elevation of the same seen at right angles to fig. 1, and figs. 3 and 4 are inverted plans of the reciprocating volutes used for mixing the gas and water in the reservoir or condenser. A A are portions of the frame which carry a table B at their top, on which is secured the condenser or reservoir C for holding the carbonic acid gas and water. This reservoir is free from all joints below its water line, the average level of the latter being indicated by the line *a* in fig. 1. Inserted through the table B are tubes *m n* for attachment of the usual bottling nipple and pressure gauge or safety valve. Connected with the frame near its base is a stationary hollow plunger D communicating below by a branch *b* with a valve box E, the valve *c* of which is arranged to open upwards and control the suction by a passage *d* through branches *c f*, one of which serves as the induction pipe for the water, and the other for the carbonic acid gas. F is the working cylinder which plays up and down outside the stationary plunger D, and is connected so as to be operated by a reciprocating yoke G driven through a crank H having play in an oblong slot *g* of the yoke. This cylinder F is provided at its upper end with a delivery valve *h* which in the descent of the cylinder allows of the gas and water entering in the up-stroke of the cylinder through the valve *c*, the plunger D to be forcibly expelled through a branch pipe I and vertical pipe J by perforations *s* into the reservoir C.

The plunger D and cylinder F act as a guide below this reciprocating arrangement, while the pipe J working through a stuffing box *i* in the table B or base of the reservoir C operates as an upper guide thereto. K is a valve for shutting off communication between the pump and reservoir C when necessary while the reservoir is full or under pressure. The gas and water which are forced out through the perforations *s* during the action of the pump are admitted into the reservoir C, or gas may be admitted to water contained therein, and to effect the mixture of the gas and water any desired number of volutes L M may be adapted to the reciprocating discharge pipe J where it projects within the reservoir C the one volute L causing the gas as it rises to work spirally outwards, and passing up into or

Digitized by Google

under the upper and larger reverse volute M to be worked in an opposite direction or spirally inwards, and finally escaping by a central orifice. In this way an effectual agitation is kept up, and thorough mixing of the gas with the water is produced by the volutes as they are worked up and down within the reservoir C.

Among the advantages which are claimed for this apparatus may be mentioned dispensing with all joints above the water level in the reservoir C, the importance of which will be readily understood when the great pressure of the gas contained in the reservoir is considered, and the great difficulty that consequently exists in making a joint above the water level tight against the escape of gas. Another advantage is that the pump is aided in its descent or discharging stroke into the reservoir C by the pressure of the gas, or gas and water contained therein acting on the head of the discharge pipe or agitator that reciprocates within the reservoir. Thus the pump is aided in producing further compression or condensation by the pressure previously effected by it, or where the pump is merely used to force in the water the same is assisted in supplying the reservoir C by the pressure of the gas separately admitted thereto. In addition to these advantages may be mentioned the great simplicity of the working parts and steadiness of action, as produced by the reciprocating cylinder F on the plunger D and discharge pipe J into and through the bottom of the reservoir, the distance apart of the guides to the pump aiding in this result, and the reciprocating action of the pipe or connection J in a longitudinal direction being preferable to a rotary one for working the agitator, as offering greater security against leakage at the stuffing box.

INSTITUTION OF CIVIL ENGINEERS.

AT a meeting of the Institution of Civil Engineers, held March 3, 1868, Charles Hutton Gregory, Esq., President, in the chair, the paper read was on the manufacture and wear of rails, by Mr. C. P. Sandberg, Assoc. Inst. C.E.

This communication was divided into three parts. First, as to the best method of manufacturing rails out of common iron, and as to the time they would last. Secondly, as to the disposal of the iron rails when they were worn out. And thirdly, as to whether iron or steel, or a combination of the two materials, was the most economical to use for rails. The mode of manufacturing iron rails for Sweden, as carried out in South Wales between the years 1856 and 1860, was described; and it was stated that, with a view of ascertaining the best method, it was decided to submit a number of sample rails, made from five different kinds of "piles," to actual practical trials. These experimental rails were laid down at the Camden Town station, by permission of the London and North-Western Railway Company; and the following table showed the number of tons passed over each description of rail before it was crushed, and also before the rails were taken up:—

Mark of Rail.	Crushed.	Worn Out.
	Tons.	Tons.
T	3,680,000	5,060,000
Y	4,140,000	5,290,000
H	3,220,000	5,060,000
E	6,900,000	8,970,000
N	3,220,000	5,520,000

A table, calculated from the above, showed how long the rails would last, supposing them to be passed over by 3,000 trains yearly, each train being composed of an engine weighing thirty tons, and of twenty waggons of ten tons each, or a gross load of 230 tons. From these tables it was ascertained, that the five different descriptions of rails were on the average crushed in six years, and worn out in nine years. The conclusion was thus arrived at, that hammering after the first welding heat, for this particular kind of iron, did not improve the endurance of the rails, but that the simplest mode of manufacture had also the material advantage of being the best. These trials at the same time established the fact, that it was not the wear or the diminished sectional area caused by abrasion, which produced the unsatisfactory results in the endurance of iron rails, but the lamination caused by imperfect welding. This explained the great difference between the wear of rails made in exactly the same way, the welding in the one case being perfect, whilst in the other it had been very imperfect.

These experiments also confirmed the rule laid down in Mr. R. Price William's paper, "On the Maintenance of Permanent Way," viz., that the endurance of rails might be measured by the product of the speed and of the passing weight. Trial rails, of the same kind of manufacture as those marked E in the previous table, but of a heavier section, laid on the Great Northern Railway, might thus be said to have borne 276,000,000 tons at a speed of one mile per hour. The endurance of the rails tried at Camden Town, under unusual conditions, where the wear was occasioned principally by the frequent use of the brakes and by continual shunting, was much less, and might be represented by 120,000,000 tons at a speed of one mile per hour. These experiments seemed to indicate that 220,000,000 tons might be carried over rails, of the section and make referred to, at a speed of one mile per hour; so that any railway company, knowing the load which yearly passed over their line and the speed, might by multiplying the one into the other, and dividing this product by 220, ascertain the life of iron rails in years.

The conclusions the author had arrived at were, that no rule could be laid down for the manufacture of rails that would apply to every manufacturing district; but that in the case of Welsh iron, to which he had more particularly referred, it had been proved that the best method of manufacturing the rail was that now most commonly practised, viz., rolling the iron into bars, piling these, and repeated rolling to the finished rail, without hammering. The author assumed that the prejudicial result from hammering was owing to the large amount of sulphur in the Welsh iron. Where the iron contained more phosphorus, and less sulphur, as, for instance, in the Cleveland, Belgian, and French iron districts, hammering had proved beneficial, and rails had been made direct from puddled bars, without the intermediate process of piling—this being, in fact, the method generally adopted in those places, and being found to answer best.

As to the disposal of the rails when worn out, and as to the possibility of re-rolling old rails with advantage by companies far removed from the seat of manufacture, such as the British Colonies, the country round the Mediterranean or the Baltic, the author thought that for railways near the seat of rail manufacture, the best way would be to continue to sell the old rails to the rail mills. For other countries, situated like Sweden, for instance, it became important to ascertain whether it would not be more advantageous to re-roll them. On this subject precise and detailed calculations were entered into, which led the author to think, that the manufacture might be carried on in that country with advantage, using Swedish Bessemer steel for the head, No. 2 iron for the foot or flange, and old iron rails for the remainder of the pile.

In the third division of the paper, as to the best and most economical material to be employed for rails, the following calculations were made:—Assuming that, under a very heavy traffic, common iron rails would last five years, steel-top rails fifteen years, and solid steel rails thirty years, and that iron rails would cost £7 per ton, steel-top rails £10 per ton, and solid steel rails £15 per ton, and that the old steel-top and iron rails were valued at £1 per ton, and the old solid steel rails at £8 per ton, then, with a rail section of 81lb. per yard, 250 tons of rails would be required for one English mile of double line, and the cost of laying the rails might be estimated at £1 per ton. On these assumptions the author has calculated the following

ANNUITY TABLE, No. 1.

Interest calculated in each case at 5 per cent,

Prices. Per ton.	When Iron Rails last.	Annuity would be for: Iron Rails.	Steel Top Rails.	Solid Steel Rails.
Iron Rails £7				
Steel Top do..... 10				
Solid Steel do. ... 15				
	Years.	£	£	£
	2	587	395	325
	3	417	307	271
Credit for Per ton.	4	332	247	245
	5	280	218	239
Old Iron Rails ... £4	10	179	163	205
„ Steel Top do. 4	15	134	148	201
„ Solid Steel do. 8	20	130	140	200

This table might be thus explained, as to iron rails lasting five years:—

	£.	s.	d.
250 tons, at £7 per ton . . .	1,750	0	0
Cost of laying down . . .	250	0	0
	£2,000	0	0
Which sum at the end of five years, at 5 per cent. compound interest, became . . .	2,552	0	0
The difference between this sum (viz., £2,552) and the value of the old rails (250 tons, at £4 per ton=£1,000) was .	1,552	0	0
The annuity required to recoup this latter sum in five years was	£280	0	0

It might be objected that the prices quoted for solid steel rails were too high. Rails of this kind had been sold in some places as low as £12 per ton, but for the best quality the present price was £15 per ton, and it was only from these that the experience had been gained, as to their enduring six times as long as iron rails. However, Table No. 2 had been calculated for the different kinds and periods at the following prices, viz., iron rails at £6, steel-top rails at £9, and solid steel rails at £12 per ton, crediting the old iron and steel-top rails at £3 per ton, and the old solid steel rails at £5 per ton.

ANNUITY TABLE No. 2.

Prices. Per ton.	When Iron Rails Last.	Annuity would be for: Iron Rails.	Steel Top Rails.	Solid Steel Rails.
Iron Rails £6				
Steel Top do..... 9				
Solid Steel do. ... 12				
	Years.	£	£	£
	2	574	382	288
Credit for Per ton.	3	404	283	233
	4	319	234	230
Old Iron Rails ... £3	5	268	206	174
„ Steel Top do. 3	10	166	149	168
„ Solid Steel do. 5	15	133	136	163
	20	117	126	150

This table showed that in all cases solid steel rail were the cheapest. The amount of traffic must, therefore, decide which material it was the most economical to use for the maintenance of the permanent way. For all railways where ordinary iron rails were worn out in five years, or in a shorter time, solid steel rails were the most economical, at the prices quoted in Table 1. Where ordinary iron rails lasted over five and up to ten years, steel-top rails would be the cheapest; iron rails in these cases being clearly proved to be the most expensive, although the cheapest where they lasted from fifteen to twenty years.

The preceding tables referred to rails of the Vignoles section. Table No. 3 had been made up for the ordinary double-headed rail, for one English mile of double line, according to the prices stated, the considerations being the same as in Table No. 2, excepting that the chairs had been taken into account. Allowance had been made for 140 tons of new chairs per mile at £5 per ton, credit being given for the value of the old chairs at £2 10s. per ton. It might be observed, that steel-headed rails were here estimated to last four times, and solid steel rails eight times, as long as ordinary iron rails,—that was making allowance for the use of both faces.

ANNUITY TABLE No. 3.

Prices. Per ton.	When Iron Rails Last.	Annuity would be for: Iron Rails.	Steel Top Rails.	Solid Steel Rails.
Iron Rails £6				
Steel Top do..... 9				
Solid Steel do. ... 12				
Chairs (140 tons per mile) 5				
	Years.	£	£	£
	2	780	379	296
Credit for Per ton.	3	751	291	249
	4	436	244	228
Old Iron Rails ... £3	5	366	223	217
„ Steel Top do. 3	10	229	177	199
„ Solid Steel do. 5	15	183	166	
„ Chairs 2/10	20	163	162	

Table No. 3 indicated that the iron rails were in no instance the cheapest; but, on the contrary, that when iron rails lasted only five years, solid steel rails had the advantage, and where iron rails had a longer duration, then that steel-headed rails where the most economical.

Another fact had still to be taken into consideration—the safety of the three different materials, in regard to high speeds, severe climate, &c. A report recently published by Professor Styffe, the Director of the Government School of Mines at Stockholm, showed the extent to which the tenacity and elongation of various materials were influenced by the amount of carbon they contained. From the tables which accompanied the report it appeared that the hardest material had the greatest absolute strength, both before and after permanent set had

Digitized by Google

taken place, but it had the least ductility; on the other hand, a softer material had the greatest tenacity or elongation, the Bessemer material giving the same results as that prepared from the same pig iron by puddling, refining, or the cast-steel process. In a diagram illustrating these results, the per centage of carbon and of phosphorus was stated in nearly all cases. The limit for the amount of carbon seemed to be for the Bessemer material 1·2 to 1·5 per cent. With a larger amount the absolute strength, as well as the tenacity, had been found to decrease. When the amount of carbon did not exceed 0·4 per cent., and the material was not worked at too low a heat, the elongation seemed to be 16 per cent., or the same as for puddled iron from the same pig iron; and, as such Bessemer material was not only much stronger, but also more solid or homogeneous than the puddled material, it deserved a decided preference for all railway purposes. The few cases of the failure of rails by breaking might be accounted for as the result of too hard a material not perfectly manufactured, having been made at an early period of the introduction of the process. The experience which had now been gained should certainly prevent any recurrence of this.

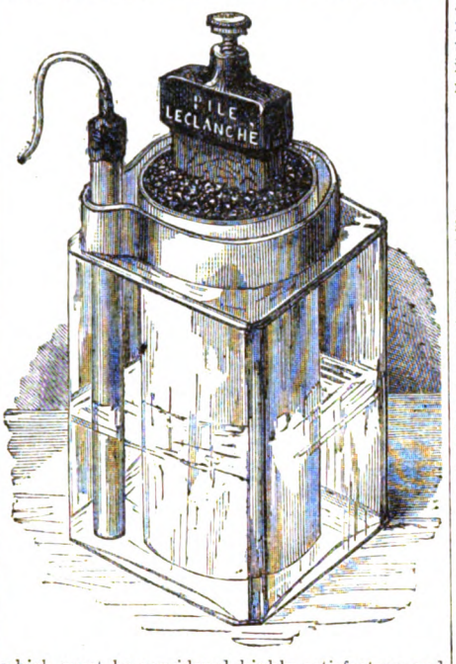
It must, however, be observed that the raw material used in both cases was charcoal pig iron, of a superior quality compared with that used in England for making Bessemer rails, which might be seen from analyses made by two eminent chemists of both countries, which were given. These analyses showed that the great difference between the two was the excess of silicon in the English, and of manganese in the Swedish pig iron; thus explaining why the one gave a better product than the other, although worked entirely without the addition of spiegeleisen. If there were only 0·6 per cent. of carbon in the solid steel, and 0·3 per cent. in the steel for the steel head, the safety ought to be the same for all the three kinds, and this would not influence the former calculations as to which was the best and most economical material for rails.

Having watched the development of the Bessemer process in England, as well as on the Continent, it seemed to the author, that by that process a good and pure raw material had the same advantage over an inferior one as in all other processes, and that a superior product could not be obtained from an inferior raw material by that process any more than by any other. In having mentioned Swedish material as an example, it must not be supposed that it was wished to advocate the use of Swedish iron in this country, but simply to draw attention to the better material; as equally good charcoal iron could be supplied from Canada and India—both English colonies. It might also be remarked, that the author's endeavour had been to arrive at the truth irrespective of prejudice, and that he had no wish to be deemed an advocate for one kind of rail more than for any other.

PEROXIDE OF MANGANESE BATTERY.

THIS battery, the invention of G. Leclanché, has excited a good deal of attention lately from its proving a constant battery, a fact that does not usually accompany single liquid batteries. It differs in many points from other batteries that have been used for electric and telegraphic purposes; as no description has up to the present time been before our readers we give now some details of its construction and working, as it evidently appears that it will come into more general use. M. Leclanché has given his attention a great deal to this subject, and seeing how unsatisfactory was the work done by most of the batteries as practically applied, he set himself to solve the following problem, "to obtain a theoretical battery in which the chemical actions being always perfectly equal to the amount of work done, necessarily leave it, without supervision, a duration equal to that work;" this solution he hopes he has found in his peroxide of manganese battery. Peroxide of manganese possessing considerable conductibility, analogous to metals, made him think that it was possible to construct a constant single liquid battery having a plate of this metal as a positive element. The chemical composition of peroxide of manganese shows that it is inoxidizable and insoluble, and that it has great affinity for decomposable bodies. As negative element he has chosen zinc, seeing that it possesses the qualifications required by theory. For the liquid solution he found it necessary to employ such as would not attack either of the two bodies, and he found that only the salts of alkaline metals would be completely inoffensive. Of the various salts tried, the salts of ammonia were found to answer best, as they allowed the depolarization and the decomposition of hydrogen to operate the most freely. With the salts of ammonia a battery was obtained which produced a current of great electro-motive force, and which allowed rapid depolarization. For practicable purposes the plate of peroxide of manganese is not used, but pounded peroxide in a porous jar, the electricity obtained from it being collected by means of a carbon plate, chlorhydrate of ammonia—the sal ammoniac of commerce—being used as the salt.

M. Leclanché says that in order to obtain good results it is necessary that care should be taken in choosing a pure peroxide of manganese and a good conductor of electricity, the manganese he recommends possessing the following external appearance—crystallized, silky, and having a marked black plumbago brilliancy, and a certain hardness. It requires to be broken into large grains and separated from the powder and mixed with an equal quantity of pounded carbon. The use of large shows a great superiority over small grains. The solution of the salt requires to be concentrated, and care has to be taken that the solution does not reach more than half-way up the porous vase, as the drier the contents of the vase are the better the conditions of working and of conductibility. From his experiments the electro-motive force appears to be considerable. Taking a sulphate of copper cell as 1·, the electro-motive force of this new battery is 1·382



which must be considered highly satisfactory, and in practice a series of forty Daniell's may, he states, be advantageously replaced by twenty-eight elements of peroxide of manganese. In proof of its excellence we may mention that up to December last, 20,000 elements of this battery were in use on different French and other railways; and in numerous stations, supplied nearly two years ago, the batteries have continued to work with a regularity conformable to the above-mentioned theory. Our illustration will explain the appearance of the battery.

The great disadvantage that almost every battery up to the present time used for purposes of practical telegraphy possesses is the amount of supervision that is always necessary; they frequently want fresh material, and do not work long before they require a thorough cleaning, and any battery that will answer for continuously working telegraphic and railway signal circuits without the looking after that the present batteries require, and will last for more than a year, will, we feel sure, be looked upon as a great boon, not only for the absence of supervision but for the decrease in expenditure that must ensue. In a large telegraph company the amount of battery power throughout their system must be enormous. What must not be the amount of saving if a battery can be adopted that works equally well with a smaller number of elements and has a lasting power more than double?

THE NAVY ESTIMATES.

THE Navy Estimates for 1868-9 were published on Tuesday last, and we here give general particulars and amounts. They present a total of £11,177,290, and the net amount, after deducting estimated extra receipts and repayments to be paid to the exchequer, is £10,733,998. The details are made up as follows:—Wages to seamen and marines, £3,036,634; victuals and clothing for ditto, £1,335,842; Admiralty Office, £182,364; Coastguard Service, Royal Naval Coast Volunteers, and Royal Naval Reserve, £263,926; Scientific Branch, £63,565; Dockyards and Naval Yards at home and abroad, £1,223,562; Victualling Yards and Transport Establishments at home and abroad, £87,179; Medical Establishments at home and abroad, £64,824; Marine Divisions, £20,709; Naval Stores, for the building, repair, and outfit of the fleet and coastguard steam machinery, and ships built by contract.—Section I. Storekeeper General of the Navy, £892,908; Section II. Controller of the Navy, £1,092,500; new works, building, machinery, and repairs, £814,237; medicines and medical stores, £78,164; martial law and law charges, £20,365; miscellaneous services, £175,800; making a total for the effective service of £9,352,579, against £9,117,758 for last year. To be added to this is half-pay, reserved half-pay, and retired pay to officers of the Navy and Royal Marines, £700,166; military and civil pensions and allowances.—Section I. Military pensions and allowances, £550,447; Section II. Civil pensions and allowances, £223,498; making a total for the naval service of £10,826,690. To this amount is added a further sum for conveyance of troops, £350,600; making a grand total of £11,177,290, against £10,976,253 for the last financial year, or a net increase of £201,037. The total number of seamen for whom provision is made is 52,070; of marines, 14,700; and of civilians, 350; making an aggregate force of 67,120.

ROYAL GEOGRAPHICAL SOCIETY.

AT the ordinary meeting of this Society, on Monday last, a paper was read on the geography and mountain passes of British Columbia, with reference to an overland route, by Mr. A. Waddington, a gentleman who has devoted many years in exploring, personally or by his agents, the different valleys and passes in order to ascertain which is the most practicable for a waggon road and railroad from the Pacific across the Rocky Mountains. In explaining the nature of the country, the author said that the two mountain ranges—the Cascade or Coast Range, having an average width of 110 miles, and the Rocky Mountains a width of 150 miles—nearly meet on the southern frontier of the colony; but diverge farther north, and leave a fertile central plain 120 miles wide. In the southern part of the country all attempts to discover practicable passes had been in vain, and no through route was possible by way of the mouth of the Frazer River. He had examined the various long inlets or fiords to the northward, and found Bute Inlet to be by far the most suitable as the Pacific terminus of the future overland route. He had discovered a river flowing into the head of the inlet, and had planned a dray-road through the narrow valley thus formed through the whole width of the Coast Range. The road that he had projected ran north-eastwardly across the plain, and struck the Upper Frazer, opposite the mouth of the Quesnelle River; the Frazer is here a navigable stream, and affords a route to the Yellow-head Pass of the Rocky Mountains, which leads to the rich level country on the eastern side of the range, extending towards the Red River Settlement. The yellow-head Pass, according to Dr. Rae, is 3,760ft. above the sea-level, the central plain is 2,500ft. in its southern part, and the Bute Inlet trail runs across it between 51deg. and 53deg. N. lat.; the pasture is excellent and the cereals (including wheat) can be grown. Mr. Waddington stated that the Canadian Government had already begun to construct the eastern end of the overland waggon-road between Lake Superior and Red River, but that no arrangement had yet been entered into with regard to the other section; and he urged the importance of the undertaking, on political and commercial grounds.

The president, Sir Roderick Murchison, bore testimony to the great geographical value of the map constructed by Mr. Waddington, on which all his various explorations were recorded. Captain G. H. Richards, R.N., Dr. Cheadle, Mr. Dallas (late Governor of the Hudson Bay Company's territory), Dr. Rae, Mr. Frederick Whymper, and others, took part in the discussion which followed.

A DESPATCH from the English consul at Zanzibar, dated 11th November, contains no positive news respecting Dr. Livingstone, but states that a white man is said to have been seen beyond the spot where Dr. Livingstone is said to have been murdered.

EXPORTS OF MACHINERY.

NOTWITHSTANDING the outcry about the damaging effect of foreign competition upon our engineering trade, when it comes to actual figures, we find that we have not had such a bad year after all. Facts and figures are stubborn things, and what they say in a late return is, that during the past year the foreign and colonial demand for British steam engines has been tolerably good, the value of the exports in the eleven months ending November 30, being £1,829,578, as compared with £1,611,442 to the corresponding date of 1866, and £1,797,435 in the first eleven months of 1865. It is worthy of note that a decrease, instead of an increase, would have been observed in the demand for British steam engines last year, but for the very large deliveries of locomotives to the Indian railway companies. Thus, the value of the steam engines sent to British India to November 30 last year was no less than £857,627, as compared with £457,987 in the corresponding period of 1866, and £271,298 to the corresponding date of 1865. The exports of other British machinery remained about stationary last year, having attained a total of £2,781,928 to November 30, as against £2,785,908 in the first eleven months of 1866, and £3,015,249 to the corresponding date of 1865. In the ten years ending 1866 inclusive the value of the steam engines exported from the United Kingdom was as follows:—1857, £1,069,249; 1858, £1,097,278; 1859, £973,340; 1860, £1,238,333; 1861, £1,258,164; 1862, £1,624,876; 1863, £1,595,036; 1864, £1,617,117; 1865, £1,958,533; and 1866, £1,750,492. The value of the exports of other machinery during the same period is subjoined:—1857, £2,814,420; 1858, £2,502,074; 1859, £2,757,961; 1860, £2,599,488; 1861, £2,955,506; 1862, £2,467,797; 1863, £2,772,976; 1864, £3,231,475; 1865, £3,264,100; and 1866, £2,998,692.

TIMBER SUPPLY FOR INDIA.

AS the more useful woods hitherto used in India are becoming more scarce, it may be important to know that the forests of Johore contain a variety of timber trees well adapted for use in that country. Upwards of two hundred different kinds of trees exist in the Johore forests, many of them not of much value, but there are some species that for strength and durability cannot be surpassed. Amongst these may be mentioned Baloo, called Johore teak by the Europeans at New Johore. It appears to be a species between saul and teak. This timber has been sent in some quantity to Calcutta and Bombay. Sir Macdonald Stephenson, who visited these forests a few years ago, was the first to introduce it to the notice of the great railway companies. It is worth mentioning that Sir Stamford Raffles in the year 1823 got the Sultan and Tumungong "to forego all right and claim to this wood within Singapore and the islets immediately adjacent." Since then all on the island has been disposed of, most of it going to China, where it is much esteemed and is still in demand.

A grave mistake has been committed in sending some young timber into the market; this timber invariably splits more or less. Attention has been drawn to the prevention of this by Mr. Kruger, who recommends that the trees should not be felled until they are perfectly full grown, and that a year previous to felling they should be "ringed." Subjoined are some experiments of various woods, which we find in the last number of the Calcutta "Engineers' Journal;" it will be seen that the Johore kinds stand the tests well. It may be mentioned, says the above paper, that, owing to the exorbitant duty levied on timber from Johore, comparatively little business has been done in it here. There is no duty whatever on timber imported into Great Britain. As timber goes to improve a country, and as the lower classes in India cannot afford to take much of it in consequence of its price, the abolition of the impost would be highly desirable. The Maharajah of Johore levies no duties whatever on British goods and in justice ought to enjoy reciprocity. A tax of ten per cent. is levied on the export of timber by the Johore Government. There are extensive steam saw mills, at New Johore in full operation. The harbour is capacious and safe; vessels of any draught can load alongside the saw-mills wharf. The Maharajah, a K.C.S.I., is an enlightened ruler, and since his return from England last year, he has begun to make roads, build houses, open up new plantations of gambier and pepper, and otherwise improve his country. He maintains an English school, and is anxious to do all the good he can. His family has always been on the best of terms with the British; it was from his grandfather that the now flourishing settlement of Singapore was originally obtained.

REPORT of TESTS OF SPECIMENS OF TIMBER made for the Inspector-General of Ordnance, Bombay, by LIEUT.-COL. J. B. HATCH, Agent, Gun Carriage Factory, Bombay, in April, 1866.

Description of Timber.	No. of Specimen.	Weight of ditto.	Dimension of Specimen.			Weight at which broke.			Nature of Fracture.	Deflection previous to Breaking. Inches.	Test for direct cohesion, each piece turned down to 1-diameter. Weight at which Broke.			Remarks by J. MELDRUM, Manager Johore Steam Saw Mills Company, near Singapore.

THE MONT CENIS TUNNEL.

THE Mont Cenis Tunnel entered upon a new phase at the commencement of the present year when the works were handed over to a new company to carry out. This company has at its head the engineers Sommeiller and Grattoni, two of the first projectors of the great undertaking, and whose names have throughout been honourably associated with it. The company undertakes to finish the tunnel in four years, ending the 31st of December, 1871, and to pay a stipulated forfeit for every month beyond that time during which it shall not have been completed. If it ends the work before that time the same sum is to be paid to it for every month gained. The "Savoy Journal" says the tunnel is pretty sure to be finished early in 1871, but that this will hardly be the case with the two pieces of railroad which are to connect St. Michel and Susa, the present termini of the railway north and south of the Alps, with the extremities of the tunnel. Ground has been broken on this side, but upon the other it will not be begun until the end of the winter. The work will be carried on with the utmost activity. It is estimated that if 6,000 to 7,000 workmen be employed on the North-Alpine section—and it is said that the configuration of the ground and the limited resources of the country will not admit of a larger number—the line can hardly be opened in less than four and a-half to five years, which is also about the time that will be needed to complete the section from Bardonneche to Susa. The work on those two pieces of line will be of great magnitude and extremely costly. It is estimated at from 1,700 to 1,800 thousand francs (£68,000 to £72,000) per kilometre. The average price in France is only from £10,000 to £12,000. The cost of the tunnel itself is estimated at from four to five millions of francs per kilometre. It seems that Mr. Fell, if he soon begins running his trains, is likely to have a good five years' traffic over the summit of Cenis. The summit railway line and the covered ways were ready two months ago, but some parts of the engines, which were made in Paris, would not stand the tests applied to them, and it was found necessary to replace those parts by corresponding ones of greater strength. One of the experimental engines has been working in a most satisfactory way all along, and carrying materials for the covered ways.

UTILIZING WASTE COAL.

A SERIES of carefully-conducted experiments have been made by a Board of Engineers, appointed by the United States' Navy Department to examine into the various methods of employing anthracite and bituminous coals as fuel, at the works of Messrs. Whelpley and Storer, East Boston, Mass. A furnace for burning pulverized coal was there erected, which the owners have used for several years in their ingenious process for the reduction of metallic ores. No official report of the combustion trials made with this furnace has yet appeared, but the results are thus briefly stated in the "New York Tribune." A series of experiments, each lasting forty-eight hours, showed the relative heating power of bituminous coal in lumps of four inches cube, burned on a grate with a forced blast under an ordinary tubular boiler, and the same kind of coal, one-third in lumps burned on a grate, and two-thirds slack pulverized, and driven in above the fire with a forced blast. Under conditions as nearly alike as practicable it was found that an average of 1lb. of lump coal evaporated 8½lb. of water from a temperature of 140deg. Fahrenheit, while one-third of a pound of lump coal and two-thirds of a pound of pulverized coal evaporated 9½lb. of water from the same temperature. The combustion was so perfect that in neither case were the residual ashes more than 8 per cent. of the coal used. In the latter part of the experiment the increased useful effect of pulverized coal over lump coal rose from 12 to 30 per cent., owing to the acquired skill of the firemen in increasing and regulating the heat. Assuming that the heat generated by pulverized coal is barely equal to that of lump coal, these experiments solved most satisfactorily the question what is to be done with the vast quantities of fine fuel which now lies at the mouths of coal mines in this country and in Europe. Statistics show that while the mines of Great Britain yield more than 100,000,000 tons of marketable coal per annum, about 30,000,000 tons more of waste coal are left at the mines. The percentage of waste coal at the anthracite mines of this country is somewhat less than at the bituminous coal mines, yet it has been estimated at about twenty-five per cent. of the whole weight brought to the surface. The utilization of this waste coal would virtually add one-third more to the value of the annual product of American mines, and eventually cause a corresponding diminution of the prices paid by the consumer; therefore, it may be safely averred that no improvement has been lately proposed which compares in general importance with that which would make available the waste product of coal mines. The inventors of this process of utilizing fine coal are about applying their apparatus to locomotives. Previous experiments have demonstrated that at least one-third of the air required for combustion should be admitted above the fire in the locomotive, and the remaining two-thirds under the grate bars. Still the waste resulting from rapid and imperfect combustion required in the locomotive is very large. It is claimed that by pulverizing coal and admitting it in combination with air above the ordinary coal fire, the rapid generation of heat is successfully accomplished; and what is still more important in the locomotive, that there is an almost entire absence of smoke and particles of unconsumed coal, which in spite of spark-arresters have been thus far the disagreeable and dangerous resultants of accelerated combustion. The trials to which we have referred relate only to bituminous coal. It would be interesting to know whether the same advantages can be gained by pulverizing anthracite, which requires a much higher degree of heat for its ignition.

Correspondence.

SQUARING THE CIRCLE.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

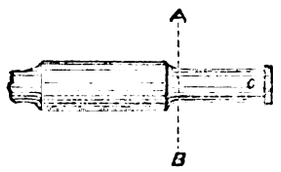
SIR,—To the Rev. Dr. Maskelyne, Astronomer Royal in 1767, navigators are indebted for the "Nautical Almanack." The moon's theory, based upon Kepler's laws of planetary motions, was then so perfected as to enable the Doctor to supply the angular distances of the moon from the sun, and certain fixed stars, at every six and three hours, so as to enable the navigator to determine his longitude by lunar observation. The lunar distances are computed by spherical trigonometry; they are computed for one, two, three, or more years in advance; and as the computed distances agree exactly with the observed distances, the accuracy of the value of trigonometrical lines may be safely accepted. But we need not go beyond our planet for a verification of the accuracy of our present trigonometrical tables; we may reasonably rely upon the trigonometrical survey of England.—I am, sir, yours, &c.,

March 9. COMMANDER, R.N.

FRACTURE OF AXLES AND BOILER PLATES.

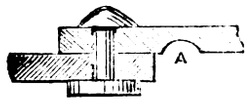
SIR,—Amongst the numerous discussions and descriptions of experiments upon iron and steel which have lately taken place, there is one important element that does not appear, and which enters apparently unheeded into the construction of all our metallic works. I would, therefore, ask those who are so disposed to answer the following questions which will bring forth the element referred to.

First. Taking a railway axle: why should it crystallize, and why on the line A B, leaving the part C almost sound?



Second. If two equal spans of a bridge be built, one on the plan of the Charing Cross bridge, and the other on the plan of the London, Chatham, and Dover Railway, across the river, each span to be of equal strength when erected, and having the same amount of traffic passing over them, why, by construction alone, should one bridge last considerably longer than the other, and which one will give way first?

Third. In the case of steam boilers which I have noticed, why should the plates at their lap be eaten out above the water line, as at the point A?



I have put this in the form of queries, to see how far the element referred to has been considered; and if not satisfactorily answered will, at a future day, with your permission, reply in your columns.—I am, Sir, yours, &c.,

C. and M. E. and ELECTRICIAN.

SPEED OF THE "WATERWITCH."

SIR,—I am much interested in Mr. Ruthven's mode of propelling steam vessels, and observe from the account given in your Magazine of February 28, that in the recent trials the "Waterwitch" attained a speed of about nine knots an hour.

You propose that some experiments should be made on the blades of the turbine, to try if by this means the speed could be improved. I understand that the water which supplies the turbine is drawn from the bottom of the vessel, which has a tendency to pull her down. I would, therefore, further suggest that the pipes for supplying the turbine should be carried forward towards the bow of the vessel. The pressure being taken off the orifices of the pipes in that position would have a tendency to move the vessel forward, instead of pulling it downward as at present, and thus you would have the drawing force forwards to add to the propelling force behind, which, with the same expenditure of power, would produce a considerable increase in the speed of the vessel.—I am, Sir, yours, &c., WM. FREW.

6, Mill-street, Perth, March 10.

MESSRS. CARRETT AND MARSHALL'S PUMPING ENGINES.

SIR,—In your journal of the 21st February, 1868, wherein you give a large cut of our combined engines and pumps for waterworks and other purposes, for forcing any distance or height in one continuous stream, you state 35,000, which should be 350,000 gallons, two and a-half miles and 470ft. high in twenty-four hours.

CARRETT, MARSHALL, AND CO.

Sun Foundry, Leeds, March 10.

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of 21s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith.—T. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

RECEIVED.—J. M.—T. C.—J. P. C.—G. J. C.—M. B.—T. F. C.—J. H. W.—W. N.—R. E. J.—T. M.—H. S.—T. B.—R. F.—F. W. P.—G. E. P.—J. W. M.—T. H.—R. I.—C. B.—W. F.—G. W. H.—J. L. N.—H. C.—J. L.—A. W.—J. N.—W. Meetings for the Week.

MON.—Royal United Service Institution.—Captain J. B. O'Hea, late of the 25th Regiment, on "Cartridges for Breech-loading Small Arms, and the Best Form of Projectile," at 8.30 p.m.

Society of Engineers.—Mr. F. C. Danvers on "Engineering in India," at 7.30 p.m.

TUES.—Royal Institution.—Mr. George Scharf on "Historical Portraiture," at 3 p.m.

The Institution of Civil Engineers.—Continued discussion upon Mr. Sandberg's paper on "The Manufacture and Wear of Rails," at 8 p.m.

WED.—Society of Arts.—Mr. Robert F. Fairlie on "Railways and their Management," at 8 p.m.

THURS.—Royal Institution.—Mr. George Scharf, on "Historical Portraiture," at 3 p.m.

FRI.—Royal Institution.—Professor Matthiessen on "Alloys," at 8 p.m.

SAT.—Royal Institution.—Professor Roscoe on "The Non-Metallic Elements," at 3 p.m.

Naval, Military, and Gunnery Items.

DURING 1867 the cost of the army in India was £12,889,898, showing a net increase of £351,273, arising from the increased pay to private soldiers.

A NEW code of storm signals is to be used at Calcutta, and the meteorological department in charge of them is to give timely notice of impending storms. Four jetties are to be erected along the Hoogly.

THE steam tug boat "Enterprize," blew up at Calcutta on January 31, killing five natives, mortally injuring seven others, and injuring two Europeans and some natives. The chief engineer, Mr. T. Newton, had a very narrow escape.

OFFICIAL information is given by the United States' Lighthouse Board of the re-establishment, on February 20 last, of the light at the southern extremity of Half-Moon Reef, in Matagorda Bay, Texas. The structure is of wood, painted white, upon an iron-pile foundation painted black. The illuminating apparatus is a lens of the sixth order, showing a fixed red light. The light is thirty-five feet above the sea level, and should be seen in clear weather at a distance of six miles.

THE "Eclipse," 6, screw sloop, 1,273 tons, 350-horse power, nominal, having been fitted with surface condenser engines, which were manufactured by Messrs. John Penn and Sons, of Greenwich, and exhibited at the late Paris Exhibition, recently got up steam at her moorings in the basin, and the engines were worked for five hours with very great success, there being an entire absence of hot bearings and priming. The revolutions were 84 a minute. She will shortly be taken on a trial at the measured mile.

WE, "Pall Mall Gazette," have reason to believe that the proposed scheme of army administrative reform, which has been for some time under consideration, will shortly be experimentally tried in action. It is understood that the scene of the first trial will be Ireland, where recent military experience has practically proved the necessity of a change of system, and where Lord Strathnairn, the president of the committee on this subject, will be enabled to superintend the experiment, and overcome any difficulties that may arise in person.

OFFICIAL information is also given by the same Board that, on and after February 22, 1868, there will be shown from a lighthouse recently erected on the east end of Combahee Banks, a fixed white light of the fifth order, illuminating the entire horizon, and should be seen in clear weather at a distance of eleven miles. The substructure is of iron screw-piles painted red. The superstructure is of wood, painted white, surmounted by a lantern painted black. A fog-bell is attached to this station, which will be sounded every ten seconds in foggy weather.

LORD STANLEY, having heard that a balloon had been employed in the course of the war in Paraguay by the allies, wrote out for any information which could be obtained respecting it. It appears that the balloon has been of service, but as it could not be used with long ropes held by soldiers it was difficult to turn it to good account. General Mitre wrote of it:—"My opinion on this subject is that the balloon may be often employed with advantage in war, and that if the one we have has not been of much service it is owing to our not having known how to make proper use of it." An engineer, who had gained experience in the United States, had made observations from the balloon.

THE trial of Major Palliser's 9-inch gun, which was exhibited last year at the Paris Exhibition, has just been concluded at Woolwich. Its test was as follows:—420 rounds of 43lb. of powder, 87 of 45lb., and 4 of 55lb. of powder, with 250lb. shot throughout; in all, 511 rounds. The vent remained serviceable to the end. The great mass of this gun is composed of cast iron, which is lined with two barrels of coiled wrought iron, one inside the other. A crack appeared at the muzzle portion of the inner barrel shortly after firing 200 rounds. This, however, produced no ill effect whatever. It was caused by the vibration of the barrel, which was accidentally loose in the muzzle. The gun was manufactured by the Elswick Ordnance Company, and remains practically uninjured. The successful result of this trial proves the soundness of the advice of the Ordnance Select Committee in having recommended Government to incur the expenditure upon it.

WHILE many have amused themselves with speculations about the cause of the late earthquakes and violent elemental disturbances in the West Indies, we are all likely to be made aware before long of some of their apparent results. Since these occurrences, says the "New York Times," the current of the Gulf Stream has been observed to have nearly doubled its velocity, not only increasing the dangers of navigation among the islands and off the Florida Keys, even for steam vessels, but awakening apprehensions of still greater and more important general changes. The climatic effect of this huge hot water stream along the North European and American coasts is rarely realized. But the fact that the British Isles are in the same latitude with icy Labrador, will show what it does for our cousins, and suggest what terrible changes might be brought about by a shift in the direction of its current—which might as easily take place as increase of its velocity.

Miscellanea.

THE number of visitors at the Patent Office, South Kensington, for the week ending March 7, was 3,291; total number since the opening of the museum, free daily (May 12, 1858), 1,256,889.

THE number of Cornish pumping-engines reported for January last is twenty-three. They have consumed 1,665 tons of coal, and lifted 130 million tons of water 10fms. high. The average duty of the whole is, therefore, 53,200,000lb., lifted one foot high, by the consumption of 112lb. of coal.

LAST week, in a field near Mold, in Flintshire, forty-four teams met to compete for the honours of the day. Among the competitors was Messrs. Ransomes' champion ploughman from Ipswich; the Welshmen, however, beat this formidable opponent, and carried off the first six prizes with the ordinary ploughs of the district.

THE building-up of the Universal Exhibition was peculiarly exempt from accident; its pulling down has been less auspicious. The other day part of one of the external walls fell, crushing beneath its ruins two workmen. Their comrades lost no time in digging out their bodies. One was quite dead, but there are hopes for his unfortunate companion.

ACCORDING to the last accounts from America, new gold fields have been discovered at a locality on the Rocky Mountains, at Sweetwater, in Dacota, fifty miles from Omaha, within 100 miles of the route to be traversed by the Union Pacific Railroad, which in extent and richness, and facilities for working, are likely to surpass any yet opened up.

THE "German Petersburg Gazette" announces that a large railway company has accepted the Government terms for the sale of the Nicolai line, under reserve of the consent of a general meeting of shareholders about to be called. The contract entered into by the Government with an American firm for the supply of working material is to remain in force.

THE Duke of Sutherland attended on Thursday week, with Captain Shaw, and several members of the Board of Works, at the Thames Embankment, at the bottom of Norfolk-street, Strand, to witness the grand inspection of engines and firemen of the Metropolitan Brigade. The two floating steamers and four land steamers, with several manual engines, were tried, and two fire escapes. The whole of the machinery was pronounced perfect, and the officers and men were highly complimented for the efficient manner in which they directed the water from the engines.

Digitized by Google

THE visitors to the South Kensington Museum during the week ending March 7, were:—On Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 9,376; on Wednesday, Thursday, and Friday (admission, 6d.), from 10 a.m. till 5 p.m., 1,460—total, 10,836. Average of corresponding week in former years, 10,344. Total from the opening of the museum, 7,230,864.

THE "Hanover Gazette" announces the establishment, on the railways of North Germany, of fourth-class carriages. These, which will serve to carry ordinary travellers, are at the same time organized so as to transport wounded soldiers. For this purpose hammocks will be suspended in each carriage, in which the sufferers will be laid full length and protected against all shocks.

A MARBLE statue of Charles II. is now placed in Westminster Hall, which completes the number of statues intended to be placed there for the present, viz., Charles I., Charles II., James I., William III., George IV., and William IV. The first of a series of cartoons is now placed between the statues, representing the death of Richard III., and the crowning of the Duke of Richmond.

ACCOUNTS from Alexandria make mention of two smart shocks of an earthquake having been felt there on the 19th of February at midnight. No damage was done. It was blowing hard at the time. The Peninsular and Oriental Company's steamer "Ripon" was detained for two days outside, being unable to enter on account of the weather. Some persons in Malta say they felt a slight shock on the same night.

AT the last meeting of the Royal Geological Society, the following gentlemen were elected fellows:—Chisholm Anstey, Esq.; George Bentley, Esq.; William Bull, Esq., F.L.S.; W. H. Cole, Esq; Frederick Dutton, Esq.; R. G. E. Dalrymple, Esq.; Major Goldsworthy; Hugh Jamieson, Esq.; the Right Hon. Earl of Kellie; W. W. Lane, Esq., B.A.; Major G. D. Pritchard, R.E.; W. B. Watson, Esq.; and W. C. Wentworth, Esq.

THE "Indian Daily News" describes a tea leaf rolling machine, which consists of one or more discs rotated horizontally over a surface on which the leaves are placed. This surface, which represents regular lineal indentations, is covered over with fine matting, and its relative distance from the revolving disc is under control. The latter is bound with a loose rim, which adjusts itself to the space between the disc and the lower surface, and thus imprisons the leaves whilst being rolled.

AT the fifth general meeting of the eleventh session of the Institution of Engineers in Scotland, Mr. Jas. M. Gale, C.E., President, in the chair, the following candidates for admission to the Institution were elected:—As members, Mr. D. G. Morrison, engineer, Elliot Works, Glasgow; Mr. Alexander Morton, engineer, Albert Works, Glasgow; Mr. Edward M. Bell, manager, Tinplate Works, Coatbridge; Mr. James Thomson, jun., mechanical engineer, 13, Royal-crescent; Mr. Jas. Hall, mechanical engineer, Clutha Ironworks, Glasgow.

A CONSIDERABLE quantity of foreign gold coins of the sixteenth century has just been found in the neighbourhood of Napoleon-Vendee, the value being estimated at 30,000f. The larger part of them bear the name of Phillip II. of Spain and other Spanish monarchs, and are not difficult to obtain. There are, however, two which are comparatively rare—a gold crown of Charles III. of Savoy, called the Good, struck in 1543 during the siege of Nice, and another of Cardinal Charles de Bourbon, then Legate of Pius V. at Avignon. From the fact that none of the pieces is of later date than 1571, and that all come from Catholic countries, the deposit is supposed to have had its origin in a Spanish subsidy furnished during the wars of religion.

FOUR companies share the work of cleaning the streets of Paris, the contracts for it being obtained on sealed tender. The persons employed are divided into street-sweepers of the first and second classes, with auxiliaries, men and women. The total number in the service is about 6,000. This little army of labourers is paid, not by the day, but by the hour. The sweepers of the first class receive 38 centimes, and those of the second 29; the male auxiliaries, 25; and the female, 20. As the work is ten hours daily, summer as well as winter, the wages of the men amount to 2f. 50c., and the women to 2f. Nearly all these labourers, of both sexes, come from Alsace, Rhenish Prussia, the Grand Duchy of Baden, and Luxemburg, but chiefly from the latter.

THE North-Eastern Railway Company have set resolutely about the replacement of the whole of their numerous wooden viaducts with stone and iron, and in some places with solid embankments. Upwards of £67,000 have been spent in this way during the past five years, and it is estimated that the work yet to be done will cost £110,000 more in the next six years. The Hutton, Malton, and Whitby viaducts have been completed, the Ripon is in progress, and the Norton is being filled up. The Ouseburn viaduct will be next taken, after which the remaining works of magnitude will be the Esk Valley viaducts (two), and the Scotswood, Willington, Cassop, and Bradbury viaducts. The whole of the wooden bridges, however, cannot be finished till six years hence, and it is proposed to expend yearly a sum of about £20,000 until completion.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

BOILERS AND FURNACES—2268, 2294, 2312, 2313, 2324
BUILDINGS AND BUILDING MATERIALS—None.
CHEMISTRY AND PHOTOGRAPHY—2270, 2305, 2314
CULTIVATION OF THE SOIL, including agricultural implements and machines—2272, 2291, 2215
ELECTRICAL APPARATUS—2307
FIBROUS FABRICS, including machinery for treating fibre, pulp, paper, &c.—2269, 2281, 2299, 2302, 2306, 2323, 2325, 2333, 2336
FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—2319, 2329
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c—2298, 2311, 2338, 2342
GENERAL MACHINERY—2275, 2278, 2283, 2288, 2289, 2290, 2296, 2310, 2316, 2332, 2334
LIGHTING, HEATING, AND VENTILATING—2320
METALS, including apparatus for their manufacture—2282, 2285, 2292, 2308, 2337
MISCELLANEOUS—2271, 2273, 2274, 2276, 2280, 2286, 2293, 2295, 2297, 2301, 2303, 2304, 2309, 2317, 2321, 2326, 2327, 2330, 2331, 2339, 2340
ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—2341
SHIPS AND BOATS, including their fittings—2287
STEAM ENGINES—2284, 2300
WARFARE—2277, 2318, 2328, 2335, 2343

2266 J. LOCKWOOD. *Improvements in steam boiler and other furnaces.* Dated August 5, 1867.

This invention consists in the application of a partition longitudinally of the furnace, constructed of fire-clay, common clay, &c., and either with or without openings through it, thus dividing the furnace into compartments longitudinally, which may be fired or fed with fuel alternately, so that while the smoke or unconsumed products of combustion are issuing from one compartment, the heat from the incandescent fuel of the other part will ignite the same.—Patent abandoned.

2267 T. WHITTAKER and M. ROURKE. *Certain improvements in the preparation of waterproof paper.* Dated August 6, 1867.

This invention consists in submitting long or continuous lengths of paper to a process of oiling, pitching, tarring, or waterproofing liquid, whereby both sides become covered simultaneously with the waterproofing material, instead of and in contra distinction to treating paper in small pieces, and on one side only, as hitherto. In the process of oiling or waterproofing, the roll of paper is mounted in bearings and as it unrolls it passes beneath a guide roller submerged in a receptacle containing boiled oil, or similar liquid, by which means both sides are covered and the paper becomes saturated; it then passes between squeezing rollers, or between blades called "doctors," and on to hot cylinders, or into a heated chamber, or is otherwise dried.—Patent completed.

2268 J. BOLLAND. *Improvements in furnaces for steam boilers and other purposes.* Dated August 6, 1867.

In performing this invention the inventor makes the dead plate hollow, or with an air chamber below, into which air is conveyed from two pipes passing under the fire-grate; the air becomes heated in passing through these pipes, and in the air chamber, and then it enters an arched air chamber with perforations on the inside, and towards the fire-grate surrounding the fire-door; there are sliding dampers or other equivalents between the dead plate and the arched air chamber to shut off the communication between them when required. The firing door is hollow, and the inner partition is perforated to allow the air entering from the air chamber in the dead plate to pass over the fire-grate, and these perforations in the firing door can be opened or closed by a sliding plate, the spindle of which passes through the front of the firing door. The grate bars are made as usual, but the fire-grate is divided into two parts by a midfeather made of a perforated bent plate reaching from the bridge to within about twelve inches from the dead plate. There is a swivel damper near the bridge to open and close the orifices to the main flue alternately, and there is another damper in the main flue which is connected by levers and rod to the firing door, so that when the door is opened for admitting fuel, this damper is closed to prevent the cold air passing into the flues. The two portions of the fire-grate are fired alternately, and when fresh fuel is applied to one side of the grate, the swivel damper of that side is closed, and the smoke is then conveyed around the front end of the midfeather to the other portion of the fire grate, which is then at a red heat, and when fuel is put on the fire that had been red, the position of the swivel damper is reversed, and the smoke is carried over the other fire which has then burnt bright.—Patent abandoned.

2269 A. M. CLARK. *Improvements in reeds for weaving.* (A communication.) Dated August 6, 1867.

According to these improvements all the requisite strength and regularity is retained in the reed, while, at the same time, each tooth possesses such flexibility and elasticity as to permit of the passage of threads of varying thickness, or otherwise imperfect, after which they immediately resume their original position. The teeth of this reed are united at one end by the ordinary process of tying and soldering, while at the other end they are simply received in a grooved sheath without soldering, and without tying, if needed, the space between each tooth being obtained by means of plates threaded on a uniting rod.—Patent abandoned.

2270 T. LUTHRINGER. *A new colouring matter called Geranosine.* Dated August 6, 1867.

The patentee claims, first, the production of this new colouring matter by re-acting on the fuchsine dissolved in water or diluted alcohol by oxygen contained in bi-oxide of hydrogen, or oxygenated water, in co-operation with the mineral or vegetable acids and the action of heat. Second, the above described process for the manufacture and preparations of this colouring matter. Third, its application, industry, and more especially to the colouring, by dyeing or printing of textile fabrics, such as silk, wool, cotton, and thread, and also of paper, feathers, skins, and other materials.—Patent completed.

2271 E. J. W. PARNACOTT. *An improved construction of trenail.* Dated August 6, 1867.

The patentee claims forming trenails with a cutting edge, and capable of receiving a lateral expansion, in the manner and for the purpose described.—Patent completed.

2272 H. H. MURDOCH. *Improvements in means or apparatus for sorting, screening, and classifying corn, seeds, flour, or other substances which it may be desirable to classify.* (A communication.) Dated August 6, 1867.

This invention consists in arranging and combining a series of concentric cylindrical sieves or screens of different diameters one within the other, each sieve or screen having apertures, holes, or meshes of a different size, those of the inner screen being largest, and those of the outer screen smallest, so that the corn, &c., being fed into the inner screen, and rotary motion being communicated to the series of screens, the meshes or apertures in the inner screen will arrest the largest grains or pieces, and the remainder of the corn, &c., will fall through to the second screen, where, again, the largest grains or pieces will be arrested, the remainder passing through to the third screen.—Patent abandoned.

2273 F. RYLAND. *Improvements in pulleys for suspending window frames, and for other like purposes.* Dated August 6, 1867.

This invention consists of improvements in that part of pulleys for suspending window frames, &c., called the mortice plate. The patentee makes the mortice plate with semicircular ends, and he makes in the centres of the semicircular ends the holes through which the screws are passed to secure the mortice plate in the mortice of the window-frame or other article. He also makes the opening in the mortice plate in which the bowl or wheel of the pulley works with semicircular ends.—Patent completed.

2274 M. JONES. *Improvements in kitchen ranges.* Dated August 6, 1867.

The patentee claims constructing and arranging the flues of the top and bottom ovens of kitchen ranges, and combining the said flues with independent vertical back flues, substantially as described, whereby one or other or both of the ovens may be heated at pleasure, and the quantity of heated air circulating about them regulated.—Patent completed.

2275 E. CORNELY. *Improvements in sewing machines* Dated August 7, 1867.

The patentee claims, first, the combination with the revolving looper of the "Willcox and Gibbs" machine of an auxiliary looper under the arrangement described, whereby a "Willcox and Gibbs" machine, without changing its functions as a single thread machine, may be used as a double thread machine, substantially as described. Second, operating the reciprocating auxiliary looper by a circular excentric, substantially as set forth. Third, the combination of the oscillating lever which drives the reciprocating looper with the pitman and its extension, substantially as described. Fourth, the combination of the driving mechanism of the reciprocating looper with the driving mechanism of the rotary looper, and of the needle, by a reciprocating lever receiving its movement by an oblique pin on the connecting rod of the excentric of the main shaft, substantially as described. Fifth, in combination with the lever for driving the reciprocating looper the coupling and uncoupling device, substantially as set forth.—Patent completed.

2276 C. M'DERMOTT. *An eyelet and paper fastener combined.* (A communication.) Dated August 7, 1867.

This invention consists in forming a paper fastener with an eyelet by means of which a hole will be secured through such masses of paper as it is desired to bind together, and through which eyelet or hole tape may be passed for further securing the papers and affording means for the application of seals, legal or other. Also for the threading many separate packages of paper together.—Patent completed.

2277 A. J. PATERSON. *Improvements in cartridges and fire-arms.* Dated August 7, 1867.

The specification of this invention is too elaborate to be quoted here at sufficient length for an intelligible abstract. The invention will probably be described and illustrated in a future number of this journal.—Patent completed.

2278 F. C. MARSHALL and H. STEWART. *Improvements in machinery or apparatus for raising or forcing water or other fluids, and for the transmission of the motive power of water, steam, or other fluid or gases.* Dated August 7, 1867.

This invention is not described apart from the drawings.—Patent completed.

2279 R. H. MICHELL. *Improvements in dredging machinery, and apparatus or appliances for the stowage and discharge of substances dredged up, the said apparatus or appliances being applicable to lighters, barges, or vessels used for other purposes.* Dated August 7, 1867.

This invention consists in the following arrangements:—The patentee makes the upper tumbler or roller over which the buckets pass, and by which the bucket chain is driven, capable of being raised or lowered, so that dredging may be effected in deeper water, and higher barges may be loaded than without such an arrangement. Also he makes the upper tumbler with the ladder frame capable of being lowered to the deck when the vessel is going to sea, so that top weight may be done away with. We cannot here devote space to the details of this invention.—Patent completed.

2280 M. HAMER. *Improvements in machinery for india-rubber thread cutting.* Dated August 7, 1867.

This invention relates to those machines in which the india-rubber is caused to revolve while a cutting tool advances, retreats, and is traversed so as to sever successive strips of the material, and consists, first, in causing

Digitized by Google

the said cutter to advance at an accelerated speed. Second, in an arrangement of self-acting apparatus for causing the cutter to traverse for successive cuts. Third, in a method of adapting the cutter for different thicknesses of material. The invention cannot be described in detail without reference to the drawings.—Patent completed.

2281 T. S. CRESSEY and J. WEBB. *Improvements in apparatus for shrinking cloth.* Dated August 7, 1867.

The apparatus here employed consists of a rectangular trough of tinned iron, &c., and of a wooden box of the same length and breadth, and having a grated bottom and a close-fitting lid. The bottom of the box is fitted into the top of the metal trough, and they are fixed together. The cloth is wound tightly on a roller; it is laid upon the grated bottom of the box, and the cover is put on. The water is then boiled by a gas burner, or a small fire-grate erected under the trough, and the process is continued until the moisture has saturated the roll; or steam from a separate steam boiler may be led into the trough. The cloth, being tightly rolled up is compelled to contract uniformly as it shrinks under the influence of the moisture and heat.—Patent completed.

2282 E. T. HORSLEY. *Improvements in treating cast iron.* Dated August 7, 1867.

The object the patentee wishes to attain is, by fluxing and purifying the cast iron whilst in a state of fusion, either as it runs from the blast furnace or from other smelting furnaces, to convert it into a clear and hard substance for the casting of steam and other cylinders, and for bearings, retorts, and other articles, and to produce iron more convertible into steel, and for making steel. He attains these ends by the use of borates of the fixed alkalies (or alkaline earths), or mixtures of the same, with the alkalies, alkaline earths, or other carbonates, or mixtures of boracic acid with the alkalies, alkaline earths, or such of their salts as when heated with boracic acid yield fusible borates. He works with or without a current of electricity from a battery.—Patent completed.

2283 J. P. BINNS. *Improvements in machinery for the manufacture of paper bags.* Dated August 7, 1867.

This invention has reference to a former patent, dated August 18, 1866 (No. 2129), and the specification is too elaborate to be quoted here sufficiently in detail for an intelligible abstract.—Patent abandoned.

2284 G. HOLCROFT and W. N. DACK. *Certain improvements in steam engines.* Dated August 8, 1867.

The first part of this invention relates to an improved expansion gear for cutting off the steam in proportion to the load. The second part consists in placing a circular or segmental expansion valve within the steam valve; and the third relates to the governor by which the variations in the speed of the engine are made to act on the expansion gear above referred to, or on the steam or throttle valve. The expansion valve is moved to and fro, on and by the slide valve, and the traverse of the expansion valve is regulated by bushes through which the spindle or coupling rod of the expansion valve passes. One of these bushes has a right and the other has a left-hand thread; these bushes are screwed into the boss of a pinion, into which a rack moved to and fro by the governor gears; by this arrangement any variation in the speed of the engine causes the bushes to approach or recede from each other; consequently, the bushes act sooner or later on shoulders on the expansion valve spindle or coupling rod, and thus vary the cut-off of the steam in the proportion required. The improvement in governors consists in the combination of a weight to counterbalance the centrifugal force of the balls with arms crossing each other, and suspended to centres above the point of intersection of the arms.—Patent abandoned.

2285 A. M. CLARK. *An improved metallic alloy, and in the application of the same.* (A communication.) Dated August 8, 1867.

The patentee claims the composition of the improved alloys, to which he gives the name "minargent," the chief features being, first, the introduction of pure tungsten and pure aluminium in the alloys, as described. Second, alloying the considerable proportion of nickel, notwithstanding its known anti-affinity to aluminium. He does not confine himself to the exact proportions of each of the component parts of the alloys.—Patent completed.

2286 C. BENSON and J. BARKER. *Improvements in apparatus for preparing moulds for the casting of pipes, culinders, pillars, rollers, and other forms.* Dated August 8, 1867.

Here the model of the intended pipe, &c., is supported horizontally upon movable and adjustable bearings, by which it may be moved up so as to bear on the opposite surfaces of the mould, leaving only so much of it above the table as may be required for the time to be moulded. The parts of this table are capable of sliding horizontally on guides, and they are moved to and fro by hand, or by screws or racks and pinions, or by other suitable means, so that they may be adjustable for receiving between them models of different sizes. The parts of the table are provided with recesses or openings through which may rise guides, operated by racks and pinions, or otherwise, to retain the mould boxes in position; or such or other recesses or openings may serve to receive parts of the mould boxes. The guides may be held in position when raised by pins or studs. When the desired model has been placed in position between the parts of the table, the parts of the table are slidden close up to it; the mould box is then placed in position on the table, and the sand is rammed in the ordinary way. When this has been done to the extent desired, the model is allowed to drop from the sand by actuating excentric or other motion to the bearing of it. The box may then be turned over, when it will have the mould of the part of the model which projected above the surface of the table formed in it.—Patent completed.

2287 H. W. WITHERS. *Improvements in the construction of boats.* Dated August 8, 1867.

This invention consists in forming externally in each side of the boat a longitudinal recess of curved form, and in fitting in each recess a hollow cylindrical structure, or a corresponding solid structure, of cork or other sufficiently buoyant material. When the boat is stowed away, these structures fit into the recesses, and then form part of the ordinary contour of the boat; but when the boat is required for use, and lowered into the water, and more carrying power is required, they are turned upon their centres, so as to extend out from the sides of the boat, and thus give additional bearing or surface, whereby the buoyancy and lateral stability of the boat are greatly increased. The structures are narrowed towards their ends, so as not to interfere with the way of the boat.—Patent completed.

2288 F. WIRTH. *An improved machine for stamping letters.* (A communication.) Dated August 8, 1867.

This machine has a roller for the letters to rest on, and the roller has pins or claws arranged to project through its surface, and take hold of each of the letters lying thereon. These claws bring the letters into the proper position for another roller with gutta-percha guide wheels to seize and press them against the first roller, while the stamps which are carried by the second roller are printed distinctly on the said letters. This is done, however, without stopping the downward movement of the letters, which are guided by conducting bands into a box, where they arrange themselves in the order in which they enter the machine. In proportion as this box is filled with the letters it is moved on rails by means of an excentric pusher, and a rack, so that the box is emptied as fast as it is filled.—Patent completed.

2289 J. E. F. LUDEKE. *Improvements in apparatus for obtaining motive power, and for raising and forcing water and fluids.* Dated August 8, 1867.

Here the inventor constructs an apparatus consisting of two cones, each mounted on an axis turning in suitable bearings, and so arranged that the cones are in contact apex to apex, and along a straight line connecting the apex and base of each cone. These cones are combined with a close casing so that their bases form portions of two opposite sides of the casing, and the interior of the casing is divided into two chambers; the division on one side is formed by the line of contact between the cones, and on the other by a plane surface or wing fixed to the side of one of the cones in a radial position. The edge of this plane enters a groove cut to receive it in the face of the other cone. The two chambers into which the casing is thus divided are filled with water or liquid, and by suitable passages put in communication with the two ends of a cylinder, also filled with liquid, and having a piston working within it. Then, if motion be imparted to the axes of the cones first in one direction and then in the other, causing them to work through a small arc, a movement will be imparted to the piston and piston rod up and down, and after the first impulse is withdrawn, these motions will continue for an indefinite time, and if the piston rod be suitably connected with machinery it will drive it continuously.—Patent abandoned.

2290 W. R. LAKE. *Improvements in printing presses.* (A communication.) Dated August 8, 1867.

This invention relates to a printing press with a rotating or vibrating impression cylinder or platten, and a similarly operating type-cylinder or bed, with a straight "forme," and the improvements consist, partly, in the peculiar construction of the impression surface of the platten, and in the mode of gearing the same in connection with the type-cylinder, in order to cause the platten and cylinder to operate together to produce the required impressions upon the sheets of paper or other material introduced between them. The details of the invention are voluminous.—Patent abandoned.

2291 T. J. BAKER. *Improvements in the manufacture of wheat and other grain into flour, and in machinery connected therewith.* Dated August 9, 1867.

The patentee claims, first, the use of the fan described and shown, by which air is thrown into the millstone case, and kept at a pressure, and is also caused to partake of the rotation of the stone for cooling the stones, and keeping the metal and millstone case relatively dry. Second, the apparatus described and shown by which the material injected into the millstone case, both by the stones and fan, is divided into two separate streams issuing from the millstone case by two separate ducts, one above the line of the flotation of the dust and meal, and entirely free therefrom, the other mingled with the meal and the products of the grinding through the meal escape, and the apparatus by which such division is effected and adjusted. Third, the recess described and shown into which the air and products of the grinding are thrown, and in which a final separation is effected between the meal and dust and the air, and other gaseous matter, the latter being permitted a free escape upwards, whilst the meal and dust are detained by brushes and contractions so far as to prevent the escape of air downwards. He also claims the throwing of the upper current into the recess at a point at which it can aid in preventing the upward escape of dust or meal, as described and shown. Fourth, he claims the mode of balancing the running stone described and shown, and any modification of the same.—Patent completed.

2292 W. R. DAWSON. *Improvements in smelting titaniferous iron sands.* Dated August 9, 1867.

The patentee claims the use of sawdust or wood in small pieces or particles, either with or without small coal, in, or about in, the proportions stated, for preparing titaniferous iron sands for smelting, as described.—Patent completed.

2293 F. J. SEYMOUR. *An improved case or box for holding twine or cord.* Dated August 9, 1867.

The patentee claims a case or box for holding twine or cord constructed to be suspended from any suitable support, and provided with a brake to prevent the running out or unwinding of the twine or cord by its own weight, as described.—Patent completed.

2294 H. A. AVERY and G. PENABERT. *The application of a certain vegetable powder for removing and preventing incrustations in boilers.* Dated August 9, 1867.

This invention consists in applying a vegetable powder, found chiefly in Central America, and formed of the debris of a ligneous plant. It decomposes the calcareous parts of the water before they take effect, and thereby prevents incrustation.—Patent completed.

2295 W. J. MILLER. *Improvements in table knives and forks.* (Partly a communication.) Dated August 9, 1867.

This invention consists, first, in attaching the blades of table knives to their handles by means of a bolster formed of two parallel plates, between which the end of the ivory or other handle is inserted, the bolster being secured to the handle by rivets passing through the handle from one plate of the bolster to the other. Second, in making the bolsters of table knives of German silver, or some other hard metal or alloy other than iron or steel, and attaching the bolsters to the steel blades by brazing or hard soldering. Third, in improvements in the manufacture of metallic handles for table knives and forks.—Patent abandoned.

2296 R. HEATHFIELD. *Improvements in machinery for the manufacture of cut nails.* (A communication.) Dated August 9, 1867.

This invention relates to the "feeder," which consists of a tube slightly inclined, the end nearest the cutter being lower than the other end. Through this tube the strip of metal from which the nails are to be cut is passed, and to the tube an alternating motion of partial rotation is given in the ordinary way. To the end of the tube, and on one side thereof, an arm is fixed, parallel to the axis of the tube. The extreme or free end of this arm is bent at right angles, and has a slot or opening made in it, through which slot or opening the strip of metal passes. The outer end of the tube, or the end most distant from the cutter, is supported in a bearing which allows the tube a slight motion in a vertical plane. The inner end of the tube is pressed upon by a spring, the end of the spring being formed into a clip or bearing. The action of the feeder is as follows:—The strip of metal fed through the tube and slot, or opening in the arm, is urged forward towards the cutter in the usual manner; after one nail has been cut from the strip, the tube performs a semi-rotation, the end of the arm bearing on the bed of the machine, and constituting an oscillating centre about which the rotary motion is performed. The inner end of the tube, together with the arm and strip, consequently rise and fall in a vertical plane during the semi-rotation of the tube, the tube and arm being pressed down to the bed plate, and lateral motion in them prevented by the spring described. The action of the feeder is, after each nail has been cut from the end of the strip, to turn the strip at the same time, slightly raising it, and bringing it down again in the same position upon the bed plate, the motions being very similar to those effected by the human hand in hand-fed nail cutting machines.—Patent completed.

2297 C. HOHGREFE. *Improvements in apparatus to be applied to chimney tops.* Dated August 9, 1867.

Here the patentee employs a series of funnel-shaped rings having an inner diameter corresponding with the width of the chimney. These rings are fixed horizontally, and one above the other, with their mouths downwards, and with spaces between them. Their surfaces are curved so that the wind blowing against them horizontally becomes deflected upwards in a vertical direction, and the ascending current of air so obtained tends to draw the smoke out of the chimney.—Patent completed.

2298 H. A. BONNEVILLE. *Improvements in stringed instruments having sound boards.* (A communication.) Dated August 10, 1867.

This invention relates to the just equipoising of the resistance with the power in stringed instruments having sound boards, and more particularly in pianos, by using the same metal, so that the expansion and contraction is the same, from which results the more perfect maintenance in tune of the instrument, and a greater sonority, and consists in connecting the board which carries the pegs of the strings, which are made of wire, with that to which the said strings are fixed by forged iron bars bound together by iron connecting rods to prevent their going apart.—Patent abandoned.

2299 H. B. BARLOW. *Improvements in doubling and winding machines.* (A communication.) Dated August 10, 1867.

The patentee claims all the particular and general arrangements of the machine, and especially the use of a single instrument which, bearing both bobbin and stop motion, places them at the same time out of the reach of the moving power when a thread breaks. Also the means of stopping the bobbin instantly, and allowing the bobbin to be moved round at liberty on its axis when this motion is at the end of its course. Also the self-acting arrangement of parts described, or any equivalent system, of lifting the bobbins and disengaging the balanced catches to place them more within the reach of the attendant. Also the particular arrangement of a piece serving at once as bracket, the various parts as a stop-piece for the bobbin, and stop-piece for the counter weight of the self-acting lifter, and as inclined plane to isolate the bobbin at the end of the motion, which causes its rotation to stop.—Patent completed.

2300 J. DAVENPORT and J. KITSON. *Improvements in, or applicable to, slide valves for admitting the flow or passage of steam, water, or other fluids and gases when pressed.* Dated August 10, 1867.

This invention consists in so constructing and arranging slide valves that an equal amount of pressure will be applied to the face as to the back part of the valve; consequently, it will be in equilibrium at all times when in action, thus removing or preventing friction on the sliding surfaces. For this purpose a frame or back plate is applied to the back of the valve, which is kept in position by projections passing through an opening or openings in the ordinary cover of the valve box to about flush with its outer surface, and a flexible plate is placed over the same which overlaps the projections; also an additional cover is applied having recesses formed therein of greater areas than the areas of the steam and exhaust ports, with communicating passages through the said projections of the back plate, where other recesses are formed of equal areas to the areas of the steam and exhaust ports; and passages are also formed through the valve, so that the steam, water, or other pressed media will exert equal pressure on all sides of these parts, while the flexible plate allows for variations of expansion and contraction of the metal.—Patent completed.

2301 E. NEWBY. *Improvements in shackles or joining links.* Dated August 10, 1867.

Here the inventor so forms the iron or metal of which the joining link is made that either one of its two segments will exactly coincide and be identical in its form with the other. He employs a through pin or key which is capable of being riveted at each of its ends, thus securing them firmly together, and preventing them moving in a lateral direction or opening.—Patent abandoned.

2302 G. HODGSON. *Improvements in looms for weaving, and in apparatus for the manufacture of parts of such looms.* Dated August 10, 1867.

The first part of these improvements relates to means for effecting variation in the order of picking, particularly adapted to the use of rotary shuttle boxes. According to one arrangement the picking tappets, whilst they are controlled to revolve in the motion of the loom, are yet capable of sliding endwise on their shaft, so that either may be in position to act on its bowl or wiper arm from a picking shaft, or be out of the way to miss them, whereby several successive picks may be effected from either end of the loom, or the picks may follow each other alternately from one and then the opposite end of the loom. The improvements relate, second, to when successive picks of weft are capable of being effected from the same

Digitized by Google

side of the loom, or what is called "pick and pick," to means by which successive wefts may be lifted out of the way of the fork or feeler just before the throwing in of weft from the opposite side or selvage of the loom.—Patent completed.

2303 A. M. CLARK. *Improvements in refrigerating apparatus applicable for the manufacture of ice and for other refrigerating purposes.* (A communication.) Dated August 10, 1867.

This invention is not described apart from the drawings. —Patent completed.

2304 G. WARSOP. *Improvements in apparatus for cleaning windows.* Dated August 10, 1867.

The main object here is to enable persons to clean the outside of a window from the interior of the room. The patentee employs a frame which clamps on to the window sill or ledge, and on this frame he mounts a horizontal axis perpendicular to the plane of the window. This axis carries a stud on one side, on which a lever is mounted; it has a handle on its inner end, and at its outer end a socket is carried on spindles parallel to the stud on which this lever turns. Into this socket there is fitted a long rod, having at its upper end a brush and rubber for cleaning the window. By means of a spring this rod is drawn inwards, so as to cause the brush or rubber at its end to press against the outer surface of the window. Then, by working the handle up and down whilst the horizontal axis is caused to rock, the brush or rubber may be moved over every part of the surface of the window. The horizontal axis may be controlled either by a handle upon it, or by grasping and guiding the cleaning rod on the outside of the window. Any convenient form of brush may be fitted to the upper end of the cleaning rod; it is made removable at pleasure, and the rubber he employs consists of a palm or flat surface of rectangular form, with a projection at the back, which is jointed to the upper end of the rod, and the joint is so formed as to allow sufficient freedom to the palm or surface to turn every way, so that it may at all times rest flat against the glass, and also that its angles may be able to enter the corners of the window panes; where the surface of the window glass is curved the palm should be curved to correspond.—Patent completed.

2305 R. GIRDWOOD. *An improved composition to be applied to sheep and other animals for the purposes of destroying vermin and parasitical life thereon and for protecting them therefrom.* Dated August 10, 1867.

The patentee claims the compounding or mixing together of an oil or oils obtained from tar or resin, and an alkaline lye to form a dip or composition to be applied to sheep and other animals, as described.—Patent completed.

2306 R. EDMONDSON. *Improvements in the construction and manufacture, and in tools for the manufacture, of pickers used in looms for weaving.* Dated August 10, 1867.

The patentee claims, first, the construction of the entire frame of the picker of malleable cast iron in one piece, having the barrel part filled with bushes of buffalo hide, &c., to work upon the spindle, and with a receptacle for buffalo hide, &c., to act against the tip of the shuttle, substantially as described. Second, the mode of securing bushes of buffalo hide or similar suitable material into the barrel part of metal pickers by screw threads, or by expanding each end of a tube of buffalo hide, substantially as described. Third, the mode of folding, applying, and securing a piece of buffalo hide into a receptacle in a metal picker frame to act upon the tip of the shuttle, substantially as described. Fourth, the mechanism for screw tapping metal pickers, the method and tools for forming screwed bushes of buffalo hide, and the tools and system or method of swelling or spreading over the ends of a piece of buffalo hide which acts against the tip of the shuttle to secure it in the receptacle in the picker frame. —Patent completed.

2307 F. H. HOLMES. *Improvements in apparatus for the production of the electric light.* Dated August 10, 1867.

This invention has for its object the production of electric light by the aid of an electro-magnetic machine, so constructed and arranged that a lower speed of rotation to that hitherto required will suffice to produce the desired intensity of light.—Patent completed.

2308 C. D. ABEL. *An improved method or process for removing sulphur, phosphorus, and other impurities, from iron, steel, and other metals.* (A communication.) Dated August 12, 1867.

This invention consists in removing the sulphur, phosphorous, and other impurities from iron and steel during their manufacture by what is known as the "Bessemer" or pneumatic process, by introducing into the converting vessel carbonic acid gas either subsequent to the introduction of the air blast, or in combination therewith.— Patent completed.

2309 E. MOUNIER. *Improvements in penholders.* Dated August 12, 1867.

This invention relates to pen and ink holding penholders. The handle is in two parts, screwed together, the upper one serving as a reservoir, the lower part bearing the pen being furnished with a spring, the bottom of which terminates in a small flat plate for closing or opening the bottom of the holder, and allowing or intercepting the passage of ink. There are various details given in the specification which we cannot with advantage produce here.—Patent abandoned.

2310 E. COURTIS. *Improvements in the construction of machines for splitting, or for splitting and cutting, sarsaparilla, and other woody or vegetable fibrous substances.* (A communication.) Dated August 12, 1867.

This invention consists, first, in the application to machines for splitting or for splitting and cutting sarsaparilla, and other woody or vegetable fibrous substances, of a pair of elastic rollers of peculiar construction, whereby pieces of various size of the substance to be split may be introduced between the said rollers at the same time, and by them be presented to the splitting knife placed behind them, in such manner that, notwithstanding the variety of sizes in the pieces of the substance, the said knife shall operate to split them more nearly into two equal parts than has heretofore been possible by the use of ordinary rollers. Second, in the application to such machines of a pair of drawing rollers placed behind the above-mentioned elastic rollers, and between the splitting knife and transverse cutting apparatus where such is employed. The object of the drawing rollers is to assist the before-mentioned elastic rollers in pressing the substance against the edge of the splitting knife by gripping between them that portion thereof which has already been split, and by their revolution to draw it over the knife blade in conjunction with the pushing action of the elastic rollers, at the same time presenting the split portions to the action of a rotary or other cutter by which they are cut to the desired length. —Patent completed.

2311 A. TURNER and W. HEMSLEY. *Improvements in the manufactory of gloves, underhirts, drawers, socks, stockings, and other articles of clothing which are usually made from knitted or looped fabrics.* Dated August 12, 1867.

The object of this invention is to adapt and apply a woven fabric for manufacturing the articles of clothing above mentioned. The patentee claims, first, producing the above-named articles from woven fabrics in the manner set forth, instead of from knitted or looped fabrics, as has heretofore been the case. They claim, particularly, producing the said articles with the required degree of elasticity by cutting up a woven fabric diagonally, or (if from a tubular fabric), helically, so as to cause the warp and weft thread to run in diagonal directions across the article, as in fabrics made in braiding machinery. They also claim the application to the purposes above mentioned of a woven fabric produced by introducing the weft at an angle of 45deg., or nearly so, to the warp. Last, they claim manufacturing lined articles of clothing suitable for winter wear, by the use of a double or compound fabric produced by dividing the warp into two sheds, into one of which a light weft to form a face is introduced, while into the other a thicker weft to form the plush surface or lining is introduced, as set forth.— —Patent completed..

2312 J. H. EVERS. *Improved apparatus for generating steam.* Dated August 12, 1867.

This invention relates to that class of steam generators in which the water is regularly supplied in small quantities to a steam generator which is heated by a naked fire in such a manner as to flash the water into steam immediately upon its introduction into the steam generator. The improved apparatus is formed of a coil or coils of pipe wound round and arranged in any desired shape, so as to form a fireplace. This arrangement of pipes is placed in a sand mould of corresponding shape, and round it is cast molten iron, so as to enclose the coil or coils of pipe in solid metal.—Patent abandoned.

2313 E. B. WILSON. *Improvements in furnaces.* Dated August 12, 1867.

This invention (which has reference to a former patent dated December 2, 1865, No. 3090), has for its object the further facilitating of the descent of the fuel, and the clearing of the furnace as well as the obtainment of more perfect combustion. The invention consists, partly, in imparting a rocking motion to the inclined cast-iron plate which carries the fuel. In furnaces constructed as described in the specification of the former patent the inventor rocks this plate by a lever, whereby the fuel is agitated and assisted to descend, thus giving a continual stream of gas into the working chamber, and improving the combustion. The grid may be rocked in the same manner, and an iron plate may be continued above the grid (if such be used), if not above the opening, and likewise rocked so as to assist the descent of the fuel. He also makes the bottom of the fuel chamber in one or more pieces, which are lowered and raised by a lever; but before lowering the bottom, plates should be inserted in order to keep up the fuel; or this may be sometimes done by lifting the lower part of the bottom plates, so as to retain the fuel in its position. By this arrangement the furnace is easily cleaned out. He introduces water into the upper hot-air chamber by a pipe, or in a trough, to be evaporated by the incandescent fuel; and he introduces water into the bottom of the fuel chamber, dishing it so as to cause it to retain the same. The steam or vapour of water passes into the furnace, and is burnt with the fuel, the quantity being under regulation by a tap, &c.—Patent abandoned.

2314 A. MCDOUGALL. *Improvements in the extraction of the sulphur contained in products resulting from the alternate exposure of certain metallic oxides to gases containing sulphuretted hydrogen, and to oxygen.* Dated August 12, 1867.

The document relating to this invention are with the law officers "under objection," and cannot at present be seen.—Patent completed.

2315 J. SHANKS and J. CARGILL. *Improvements in lawn mowing machines.* Dated August 12, 1867.

This invention consists in constructing the sole plates or bottom blades for lawn-mowing machines so as to be reversible—that is to say, the sole plates or bottom blades are made with two edges, so that when one edge is worn, the plate can be unscrewed and reversed or turned round, when the new edge will be brought into contact with the cutter.—Patent completed.

2316 J. J. RAWLINGS and H. WILKERSON. *Improvements in machinery or apparatus for washing coprolites.* Dated August 12, 1867.

According to this invention it is proposed to combine with the ordinary revolving perforated cylinder and water trough an internal rotatory agitator, working inside the outer cylinder, but at a higher speed of revolution, such agitation serving not only to stir or agitate the coprolites while in the water, and so effect their more thorough cleansing, but also serves to facilitate their delivery or passage through or along such outer cylinder, whereby the process is considerably expedited.—Patent abandoned.

2317 W. SWENSON and J. E. HEILMANN. *An improved appliance to be used for carrying and holding railway tickets and labels.* Dated August 12, 1867.

This appliance consists, first, of a metallic frame formed with grooved sides, the shape and dimensions of such grooves being suitable to admit the ticket or label. The frame is attached to a piece of chain, and a spring or other catch, or a ring, by which it may be attached to a button of the waistcoat or elsewhere, and thus, if desired, be worn or carried out of sight, still always at hand in a certain fixed place when required to be exhibited by the traveller. Under the second modification the appliance for holding the ticket consists of a wire bent into the form of a loop, and formed with a point or barb at one end, while on the opposite end a hole or eye is formed. Over the body of the loop a ring slides, so that in using it for holding a ticket or label the point is pressed through the ticket or label, entering the hole in the opposite end of the loop, so that when the ring is pulled over the loop to its lower end the ticket or label is effectually retained. —Patent abandoned.

2318 W. T. ELEY. *Improvements in the means employed for rendering cartridges or cartridge cases for firearms waterproof.* Dated August 12, 1867.

This invention consists in coating cartridges when made up (or in coating the paper cartridge cases previous to being filled or charged) with wax, stearine, paraffin, &c., dissolved in coal tar or other suitable spirit or solvent in such proportions as to remain fluid or semi-fluid when cold. The cartridges or their paper cases are dipped or immersed in a cold solution of the above-named compound or materials, from which they are taken and allowed to dry, and when the spirit or solvent has evaporated, the paper cases or cartridges will be coated with a thin coating of the wax, stearine, &c., contained in the solution employed.—Patent completed.

2319 G. DAVIES. *An improvement in centrifugal apparatus for washing sugar.* (A communication.) Dated August 13, 1867.

This invention consists in providing the ordinary centrifugal tubs with an apparatus by which a wall of dry sugar of uniform thickness, concentric with the wall of the centrifugal tub, may be formed within the same, for receiving the application of jets of water for washing or purifying the sugar, and also in the mode of operating such apparatus.—Patent abandoned.

2320 H. T. EVERIST. *Improvements in apparatus used in the manufacture of gas.* Dated August 13, 1867.

This invention relates to the construction of exhauster governors or regulators, whereby a more uniform pressure may be maintained in the retorts when manufacturing gas, whatever quantity is being produced, than by the use of the exhauster without the interposition of such apparatus. It consists of a circular metal tank or covered case having an orifice in the centre of the bottom plate, through which rises to somewhat less than half its height a pipe which is connected to the outlet of the exhauster. In the top plate of the case an orifice is also cast, and over this is affixed a pipe in connection with the inlet of the exhauster. Within the case, and over the pipe first mentioned, a metallic bell or gasholder-shaped vessel is suspended by a rod working through a stuffing box in the cover, and attached to a chain which passes over a wheel on the outside of the case. The chain terminates in a rod whereon counterbalance weights are hung. In the sides of the bell two, three, or more graduated angular apertures are formed. These openings may be made either in the plain sides of the bell or in recesses constructed in it specially for the more easy passage of the gas. The bell is also provided with guide rollers to preserve it in proper position when in use.—Patent completed.

2321 E. SCORE. *Improvements in quoins or wedges for fixing type or blocks in their chases, and in appliances used therefor.* Dated August 13, 1867.

This invention consists, essentially, in forming quoins or wedges for fixing type or blocks in their chases of metal instead of wood, as heretofore.—Patent abandoned.

2322 J. J. BRIGHT. *Improved gear for actuating screw and other like propellers of navigable vessels by manual, animal, or motive power engine, and for elevating, lowering, connecting, or disconnecting such propellers.* Dated August 13, 1867.

This invention consists of a peculiar arrangement of apparatus (comprising various shafts and cog wheels) for actuating screw and other like propellers of navigable vessels, which is more particularly applicable when the vessel is not provided with steam power, and is chiefly intended for use in calms, or when entering bar harbours —Patent completed.

2323 G. and J. PILLING and F. JENNINGS. *Improvements in machinery for sewing or covering the lists or edges of fabrics.* Dated August 13, 1867.

This invention relates to machinery or apparatus for placing and securing a web of closely woven material over each list or edge of fabrics to be dyed along with the fabric, and technically known as "sewing." The improvements consist in certain mechanical parts for folding the said lists either into rolls, or upon cords, and placing the web or webs in position, and sewing it thereon; also drawing or propelling the fabric forward intermittently. An ordinary frame or table is employed, on which is supported a rotary shaft, which may receive motion by hand or other power. A groove is formed across the table, and a folding instrument is attached, which is constructed of two tongues or strips of metal twisted spirally, leaving a space betwixt them for the list to pass through. A series of guides or curved plates is also attached to guide the web and cord (when used) into proper position, and a pair of fluted rollers is employed to draw or propel the fabric forward under operation, which receives intermittent motion by ratchet wheel and pawl from either a cam, excentric, or crank fixed on the rotary shaft. The patentees employ a circular or curved needle mounted on a spindle, to which oscillatory rotary motion is given by an excentric, cam, or crank on the rotary shaft, and a rod operating a toothed segment wheel in gear with a pinion on the said spindle; also a looper or instrument for taking into the loop of a thread formed by the needle after its passage through the fabric is hinged so as to be operated by a lever and rod attached to an excentric, cam, groove, or crank fixed on the rotary shaft, which, taking into the thread, forms a loop, and transfers it to a suitable position for the needle to pass through on its next insertion.—Patent completed.

2324 B. F. STURTEVANT. *Having reference to blowers for furnaces, &c.* Dated August 13, 1867.

This invention is not described apart from the drawings. —Patent completed.

2325 H. M. MELLOR. *Improvements in circular knitting frames.* Dated August 13, 1867.

Here, in place of a wheel with radial slides, the patentee makes a wheel carrying levers, each capable of rocking on its fulcrum to and from the centre of the wheel. Each lever has a sinking nib at one end, and near its other end it rides upon its fulcrum. The sinking levers are fitted into radial slots in the periphery of a cylindrical boss which carries them, and the whole is carried round by means of a driver wheel in connection with it working on to the stems of the needles, and as each lever comes round to the point where it is to sink the yarn, a cam within the circle of the wheel act on the lever and progresses forward the end on which the nib is formed. The lever is afterwards brought back by another cam surface. Another part of the invention consists, when constructing a circular knitting frame, in using needles with spring beards able to slide in a direction parallel with the axis about which they rotate, as already mentioned, in connection with a sinking wheel having movable sinking

Digitized by Google

blades arranged either to slide radially, or as levers to rock on a fulcrum, as above set forth. Another part of the invention relates to the arranging circular knitting frames to produce work with a trick rib or seam down it from end to end, so that the work may more nearly resemble that produced on a flat frame.—Patent completed.

2326 S. R. WYBRANTS. *Improvements in utilizing certain waste materials, and in manufacturing packing therefrom.* Dated August 13, 1867.

This invention consists in using waste pieces of belting made of cotton, and other textile materials, for manufacturing packing for piston and pump rods or plungers, or other movable parts of machinery, which is effected in the following manner:—The waste pieces are washed and cleansed, after which they may be mangled, calendered, or otherwise treated; they are then laid over and caused to adhere to a thin web or sheet of textile material, such as coarse canvas, a solution of gutta-percha, india-rubber, being used to effect the adhesion.—Patent abandoned.

2327 A. SWAN. *Improvements in apparatus for evaporating or recovering lees.* Dated August 13, 1867.

This invention chiefly consists in employing or utilizing the flame and heat produced from burning lees in the ordinary pan or roaster. For this purpose the inventor places the bottom of a vertical tubular or other boiler upon, or partially upon the pan which contains the thick lees to be burnt or roasted; the flame and heat from the burning lees thus assist in raising steam in the boiler, and he employs the heat from this boiler for evaporating thin lees preferably, as described in the specification of his patent of October 16, 1866 (No. 2671). The pan or roaster is heated by furnaces in the ordinary manner.—Patent abandoned.

2328 M. F. HALLIDAY. *Improvements in breech-loading firearms.* Dated August 13, 1867.

This invention consists, first, in the particular conformation of the rear face of the barrel, the front and rear faces of a movable piece carrying the exploding pin or striker, and the front face of a fixed piece behind the movable piece, as described. Second, in an improved arrangement of extractor. Third, in the formation of an aperture below the movable piece to allow of the escape of the empty cartridge case; and, fourth, in the combination of the parts of breech-loading firearms, all as described. We cannot here give space to the details of this invention.—Patent abandoned.

2329 J. BADGER. *Improvements in kitchen or cooking ranges.* Dated August 13, 1867.

The patentee claims, first, constructing and arranging or combining the parts of the fire-grates of kitchen or cooking ranges so that the fire-grate may be raised or lowered in the fire-place, and fixed or supported at the required height, in order to increase or diminish at pleasure the depth or fire space of the grate. Second, opening and closing the chimney hole of the range, and forming a draught plate or box at the said chimney hole when the grate is an open one, by means of a door constructed and used substantially in the manner described.—Patent completed.

2330 C. E. FLOWER. *Improvements in cooling brewers' worts and beer.* Dated August 13, 1867.

The patentee claims the improvements in cooling brewers' worts and beer described—that is to say, by the use of brine or other dense solution which has been artificially reduced to a low temperature.—Patent completed.

2331 J. FAWCETT. *Improved apparatus for extracting oil from oleaginous seeds and nuts, and making oil cake for compound cake for cattle feeding.* Dated August 13, 1867.

The patentee claims the use of loose open boxes and plates, arranged and worked as set forth, for oil extracting and cake making, as distinguished from the presses now in use, and whereby the use of woollen bags, hairs, or metal substitutes may be dispensed with—Patent completed.

2332 T. WALKER. *Improvements in machinery for cutting grooves in knotchboards of stairs, ladder strings, and in other articles requiring such grooves.* Dated August 13, 1867.

Here the patentee employs arms mounted so as to be capable of being turned to any required angle, and connected together by suitable rods, which are carried by sliding pieces mounted on the arms. The material to be grooved is placed upon the rods, and is moved against a revolving cutter situate above, and is traversed along rollers or other guides for succe sive cuts. The distances apart of the grooves are regulated by a gauge piece which is mounted so as to be capable of being turned upward and downward upon a centre, and is placed in one groove to determine the position of that which is to succeed it. The gauge piece is also capable of being moved horizontally.—Patent completed.

2333 W. TURNEY and J. ACKROYD. *Improvements in jacquard machinery or apparatus used in the production of figured lace and other fabrics.* Dated August 13, 1867.

This invention consists in the employment of two driving shafts and two sets of driving cams, which communicate motion to the several parts of the Jacquard machinery or apparatus. By the employment of two shafts and two sets of cams constructed according to this invention the inventors are enabled to give a greater range to the throw of the bars.—Patent abandoned.

2334 W. B. LEACHMAN and J. HOLROYD. *Improved apparatus for pumping fluids.* Dated August 14, 1867.

The object here is to pump fluids, whether in a liquid or gaseous state, and for this purpose, within a suitable chamber furnished with orifices at the bottom and the top for injection and ejection, the patentees place a cylinder capable of revolving upon a shaft which passes transversely through and is secured to the chamber, such cylinder being provided with bearings on the outsides of the chamber through which it passes. The cylinder is so arranged as closely to fit the chamber (which is of a cylindrical formation in its side elevation) in one portion, whilst it is a considerable distance from it on the opposite side. Upon the shaft, and within the cylinder, they key a grooved excentric or cam, in which, at equal distances apart, friction rollers are placed connected with vanes or floats free to slide within grooves cut in the periphery of the cylinder, such vanes or floats always being in close contact with the inner surface of the chamber.—Patent completed.

2335 A. M. CLARK. *Improvements in fastenings for securing bayonets on firearms.* (A communication.) Dated August 14, 1867.

This invention consists in having the socket or tube of a bayonet formed with a longitudinal slot in which a spring having a shoulder or projection at its inner side is fitted, the lower end of the spring being secured by a screw, rivet, or otherwise to the lower end of the bayonet socket or tube. The exterior of the barrel of the firearm near its muzzle is provided with a projection over which the projection or shoulder at the inner side of the spring catches when the socket or tube of the bayonet is fitted on the end of the barrel, and firmly secures the former on the latter.—Patent completed.

2336 C. HOLLIDAY. *Improvements in means or apparatus for printing woven and other fabric or material.* Dated August 14, 1867.

This invention relates to printing spots and other forms or figures on the surface of fabric or material, particularly when using for the purpose paint, japan varnishes, or other matter of a semi-fluid or glutinous nature, the fluidity of which is increased by heat, so as to facilitate its application, and of which comparatively large quantities are required to be unpressed at a time, and the improvements consist in adaptations or combinations of means for applying the heat required, and by which several different colours may be so applied at the same time.—Patent completed.

2337 J. A. JONES, R. HOWSON, and J. GJERS. *Improvements in puddling and other furnaces employed for melting, boiling, or heating iron.* Dated August 14, 1867.

This invention consists in a mode of utilizing the waste heat of puddling and other similar furnaces by causing it to heat a mixture of air and steam, which mixture so heated is employed for the combustion of fuel, thereby economizing the consumption thereof and preventing smoke.—Patent completed.

2338 C. F. BOWER. *An improved combined bed, couch, and chair, for the use of invalids.* Dated August 14, 1867.

This invention consists, according to one arrangement, in providing a strong rectangular frame supported on four legs with castors, to one end of which frame there is coupled, by a hook or otherwise, a carriage supporting an invalid's chair, such carriage having the usual pair of hand-propelling wheels in front, and a swivel wheel behind.—Patent abandoned.

2339 W. BETTS. *Improvements in metallic capsules for bottles and other like receptacles.* Dated August 14, 1867.

Here the patentee produces the name of the firm with or without a special trade mark or ornamentation upon one or more parts of the body or outside of the cylindrical or conical part of the capsule itself. This may be accomplished by taking type or a printing block made the reverse to ordinary type, and applying gold size, or other suitable adhesive preparation, to such printing surface. He then presses thereon a sheet of foil, and from this sheet he transfers the impression to the side of the capsule by rubbing or pressing the foil, the flexibility or pliability of the foil facilitating the transferring of the edge to the side or curved surface of the capsule. Gold or other metallic leaf or powder or powdered pigment is then to be applied to the capsule, when the name or device will appear clearly thereon. These names and trade marks may be produced, if desired, in two or more colours by successive printings, whereby the effect of multicoloured trade marks will be obtained.—Patent completed.

2340 W. BETTS. *Improvements in metallic capsules for bottles and other like receptacles.* Dated August 14, 1867.

Here the patentee produces the trade mark in intaglio, or sunk upon the capsule, and in the interior, or upon the body, of such trade mark he produces the name of the manufacturer or firm employing the same, or other words or devices in relief. The die required for producing this trade mark should, of course, have the trade mark engraved in relief thereon, and the name of the manufacturer or firm using the capsule engraved in intaglio, or sunk upon the raised device. By adopting the method described in the specification of his patent, dated April 15, 1864 (No. 953), he is enabled to obtain a multicoloured effect, the trade mark being in one colour whilst the name or names of the manufacturer or firm using the capsule, or any other words or symbols raised within such trade mark, are of a different colour.—Patent completed.

2341 G. BUXTON and S. BANN. *Improvements applicable to axles of engines and carriages for railways and other roads.* Dated August 14, 1867.

This invention consists in mounting axles of engines and carriages of railways and other roads so that the blocks which carry them shall, independently of their usual vertical motion, be capable of swivelling upon centres, so that, if one side of the engine or carriage become more elevated than the other, the axle, by turning upon centres of motion, will accommodate itself to such position without a strain being put thereon.—Patent completed.

2343 H. BESSEMER. *Improvements in ordnance and machinery to be used in throwing projectiles, part of which machinery is applicable for other purposes.* Dated August 14, 1867.

The patentee claims, first, in the construction of ordnance, the formation of cells around the bore of the gun adapted to contain elastic meriform matter to operate by its expansion on the shot. Second, in the construction of ordnance, the employment of longitudinal flanged bars surrounded by cylinders or hoops. Third, casting ordnance with air cells around the bore, as described. Fourth, the construction of ordnance by building up flanged hoops or rings by turning such rings or hoops, and riveting the same together. Fifth, in the construction of ordnance, the employment of a tube and jacket having a space between them for the storing of compressed air, as described. Sixth, forcing the projectile into the gun by means of hydraulic apparatus, as described. Seventh, in the construction and working of ordnance, causing the projectile to form the valve closing the main air passages by which air is admitted to the rear of it for it propulsion. Eighth, the employment of studs in rifled projectiles arranged to alter their position to suit the differential pitch of the rifling, as described. Ninth, the employment of a disc or cover to the muzzle of guns, using compressed air for the propulsion of the projectile, and forming a partial vacuum in such guns, as described. Tenth, constructing ordnance in such manner that the projectile may be forced into a contracted part of the bore, and so retained until when the discharge is required it is started by the admission of air to its rear by a small valve or cock. Lastly, in ordnance constructed to throw projectiles by compressed air, the employment of a cock or valve to prevent the premature accumulation of air at the rear of the projectile, as described.—Patent completed.

PROVISIONAL PROTECTIONS.

Dated October 24, 1867.

2988 W. E. Gedge, Wellington-street, Strand. A novo kind of nail or tack for upholstery and cabinet work. (A communication.)

Dated October 28, 1867.

3028 J. de Silva, Liverpool, painter and paint manufacturer. Improved compositions for coating the bottoms of iron, steel, and wooden ships, and other navigable vessels and marine works generally.

Dated January 10, 1868.

93 J. H. Glow, Howland-street, Fitzroy-square. Improvements in the manufacture of boots, shoes, and gaiters.

Dated January 28, 1868.

302 J. D. Brunton, Leighton-crescent, Kentish Town, engineer. Improvements in machinery or apparatus for cutting, dressing, planing, turning, and shaping stone.

Dated February 6, 1868.

410 C. Brakell, Windsor-road, Oldham, Lancashire, engineer. Improvements in apparatus for measuring fluids.

Dated February 11, 1868.

456 T. Smith, Walnut Tree-walk, Lambeth, modeller and machinist. Improvements in steam engine counters or registering machines.

Dated February 12, 1868.

471 H. S. Barron, Alexander-terrace, Barking-road, West Ham, mechanical draughtsman. Improvements in double-action reciprocating pumps, by which the usual suction and delivery valves are dispensed with, and their functions performed by means of a sliding action of the barrel.

472 J. Smith, Cheetham, Manchester, bleacher, dyer, and finisher. Improvements in apparatus for boiling animal and vegetable substances, and for evaporating the solutions obtained in such processes.

473 A. F. Bayford, Hamilton-terrace, St. John's Wood, N.W. Improved apparatus for facilitating the watering of plants in pots, in conservatories, greenhouses, and other similar structures.

Dated February 14, 1868.

495 D. Elland, High Ousegate, York. Improved apparatus for signalling in railway carriages between drivers and guard.

502 G. A. F. Eichbaum, Southampton-buildings, Chancery-lane. Improvements in means or apparatus for indicating the amount of money received by omnibus conductors and other persons.

Dated February 15, 1868.

507 R. H. Rimes, Bradford, boot and shoe manufacturer. Improvements in boots and shoes.

513 A. M. Clark, Chancery-lane. An improved material applicable for the manufacture of felted and other fabrics. (A communication.)

516 J. Leetch, Birmingham. An improved apparatus for transmitting signals by pneumatic pressure.

Dated February 18, 1868.

527 J. Cronier, Hyde-road, Middlesex, boot and shoe maker. An improved universal rotary heel for boots and shoes.

528 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in kilns and apparatus employed in the manufacture of bricks. (A communication.)

530 R. Butterworth, Patricroft, Lancashire. Certain improvements in looms employed in the manufacture of smallware goods.

531 R. Baguley, Blackburn, shuttle maker. Improvements in shuttles for looms for weaving.

532 J. and J. Hinks, Birmingham, manufacturers. Improvements in portable stoves.

533 A. M. Clark, Chancery-lane. An improved vegetable extract for culinary purposes. (A communication.)

534 C. E. Brooman, Fleet-street, City, patent agent. Improvements in breech-loading firearms. (A communication.)

535 W. Perkins, Russell-place, Fitzroy-square, chemist, and G. G. Tandy, Anerly-road, Penge, Surrey. An improved preparation or compound applicable for insulating electric conductors, and for such purposes as india-rubber and other vulcanizible gums are applicable.

536 W. E. Newton, Chancery-lane. An improved material for the base of artificial teeth and for other purposes, and also an improved construction of mould for forming dental plates. (A communication.)

537 J. Thompson, Manor House, Camberwell-road, and J. Thompson, Camberwell Green, Surrey. Improvements in fastening railway rails.

539 W. Weild, Manchester, engineer. Improvements in the process of treating sewing threads to prepare, starch, dress, polish, and wind the same, and in some of the machinery to be employed therein.

540 W. Betts, Wharf-road, City-road, capsule manufacturer. Improvements in the production of trade marks or other designs upon metallic caps ules for bottles and other like receptacles, and in the apparatus or means employed therein.

541 H. Chamberlain, St. John's Wakefield, Yorkshire, civil engineer. Improvements in the manufacture of compressed bricks, and in the machinery or apparatus employed therein.

Dated February 19, 1868.

542 J. Higginbotham and L. Moore, Manchester, mechanics. Improvements in machinery for turning, grinding, and polishing rollers or cylinders composed of metal or other material.

543 T. Beeley, Hyde, Chester. Improvements in keirs.

544 R. Blezard, Liverpool, millwright. Improvements in machines for cleaning wheat and other grain.

545 J. Kirkland, Liverpool, engineer. Improvements in the construction of pumps.

546 E. Wright, Bradford, engineer and millwright. Improvements in self-acting means or apparatus applicable to steam boiler and other furnaces for the consumption or prevention of smoke.

547 W. and J. Cooke, Tinsley, Yorkshire, iron and steel manufacturers. Improvements in the manufacture of finished irons.

549 J. J. King, Glasgow, warehouseman. Improvements in sewing machines.

550 W. H. Steel, Park-road, Clapham. Improvements in hand saws for cutting dovetails, and for other purposes.

551 W. Edwards, Wolverhampton, manufacturer. Improvements in roughening the shoes of horses and other beasts of draught and burden.

552 R. P. Faucheux, Caversham-road, Kentish Town.

Digitized by Google

Improvements in reels or bobbins, and in means or apparatus to be applied thereto.

554 G. P. Dodge, Upper Thames-street, City, india-rubber manufacturer. Improvements in the manufacture of india-rubber valves, valve seats, and other similar articles.

555 G. P. Dodge, Upper Thames-street, City, india-rubber manufacturer. Improvements in packing for the stuffing boxes of steam engines, and for other like purposes.

556 F. H. Renault, Rue de la Chaussee d'Antin, Paris. An improved combined umbrella and walking stick.

557 J. G. Jones, Blaina Ironworks, near Newport, Monmouthshire. Improvements in machinery for exhausting air, suitable to be used for ventilating mines, and for other similar purposes.

558 W. S. Guinness, Cheapside, City. Improvements in sewing machines.

559 J. Lord, Oadby, Leicestershire, manufacturer. Improvements in apparatus for coupling and uncoupling railway carriages and vehicles.

560 L. B. Joseph, Upper Norwood, Surrey. Improvemens in carriage and other wheels and tyres.

562 W. Myers, Birmingham, jewellers' factor. Improvements in lockets, miniature bracelets, and miniature brooches.

Dated February 20, 1868.

563 P. Bauer, J. Johnson, and W. Jones, Manchester. Certain improvements in apparatus to be employed for lubricating revolving shafts or axles.

566 P. N. Goux, Rue de Longchamps, Paris, agricultural proprietor. Improvements in collecting and in disinfecting human excreta, and converting the same into manure, also in the apparatus or means employed therein.

567 J. H. Johnson, Lincoln's Inn-fields. Improved means for increasing the draught in steam boiler and other furnaces or fireplaces. (A communication.)

568 J. Hullett, Purbrook, Hampshire. Improvements in aeronautical apparatus.

569 J. G. Tatters, W. Keeble, and B. Newbery, Plymouth. Improvements in the preparation of cigars.

570 T. A. L. Murray, Brompton. Improvements in rails for tramways.

572 G. Davies, Serle-street, Lincoln's Inn. Improvements in taps. (A communication.)

573 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in apparatus for shearing or clipping the wool or hair of sheep and other animals. (A communication.)

575 R. Fennelly, Wellington Chambers, London Bridge, and P. Kenny, Waterford, Ireland. An improved method and apparatus for singeing off the hairs, bristles, and other matters on pigs in order to prepare them for being converted into bacon.

Dated February 21, 1868.

576 G. Davies, Serle-street, Lincoln's Inn. Improvements in the manufacture of gas for lighting and heating. (A communication.)

577 G. A. Bridgett, Rose Bank, Fallowfield, near Manchester. Improvements in steam engine slide valves, valve gear, and governors, parts of which are applicable to other purposes.

578 L. M. Becker, Guildhall Chambers, Basinghall-street, telegraphic engineer. Improvements in the manner of indicating the position and supply of fire plugs, fire cocks, fire alarms, and for other purposes.

580 W. Thompson and T. Stather, Kingston-upon-Hull, engineers. Improvements in apparatus for washing and drying grain.

581 H. Walmsley and T. W. Taylor, Manchester. A self-acting registering apparatus to register the number of persons entering into and on omnibuses, or similar vehicles plying for hire.

582 M. A. F. Mennons, Southampton-buildings, Chancery-lane. An improvement in certain descriptions of bristle brushes. (A communication.)

583 T. Altham, J. Clark, and S. Ridehalgh, Nelson, Lancashire. Certain improvements in machinery or apparatus employed for sizeing yarn, termed tape legs, being also applicable to other similar machinery.

584 T. and J. R. Bury, Blackburn, shuttle makers. Improvements in shuttles for looms for weaving.

585 J. Wheatley, East Mousley, Surrey, builder. An improved construction of chimneypot.

586 A. V. Newton, Chancery-lane. Improvements in reaping and mowing machines. (A communication.)

587 W. Wilson, Newcastle-on-Tyne, hat manufacturer. Improvements in apparatus for lubricating the sliding valves and pistons of steam engines. (A communication.)

Dated February 22, 1868.

588 A. de Metz, Wolverhampton. Improvements in commode pots or vessels to be used as water-closets or for other purposes.

590 J. M'Call, Houndsditch, City, provision merchant. An improved mode or process of preserving meat.

591 C. J. Galloway, Manchester, engineer. Improvements in wrought-iron and steel piles, pillars, and columns.

592 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in machinery for supplying type formes in printing presses with various coloured inks for each impression. (A communication.)

593 J. Needham, Piccadilly. Improved fastenings for gloves, boots, and other articles.

594 A. V. Newton, Chancery-lane. Improvements applicable to steam boiler and other furnaces. (A communication.)

595 J. J. Aston, Middle Temple, Barrister-at-law. Improvements in machinery or propellers applicable for the propulsion of ships, boats, and other vessels on and over the water.

596 B. E. R. Newlands, F.C.S., Malvern-terrace, Charlton, Kent. Improvements in treating spent oxide of iron, or oxide of iron which has been used in gas works or otherwise, to separate sulphur from sulphuretted hydrogen, and in the purification of sulphur obtained from such oxide of iron.

597 W. H. Ryland, Birmingham, manufacturer and factor. Improvements in fastenings for articles of dress and jewellery.

598 F. Sangster, Dacre Park, Lee, Kent. Improvements in parasols and umbrellas.

599 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in electrical signal or alarm apparatus. (A communication.)

600 S. Firth, Leeds, merchant. Improvements in machinery for cutting coal, stone, or other minerals.

601 E. J. Nicoll, Oxford-street, and T. M. Ablett, High Holborn, shoemaker. Improvements in waist springs for boots and shoes.

603 R. Heathfield, Birmingham, manufacturer. Improvements in the manufacture of cut nails.

Dated February 24, 1868.

605 J. W. Watts, Norway-street, St. Luke's. Improvements in machinery for preparing vegetable fibre.

607 P. H. Hancock, Tachbrook-street, Pimlico, and J. P. French, St. Andrew's-terrace, Wandsworth-road. Improvements in printing machines.

609 J. Macintosh, North Bank, Regent's Park, and W. Boggett, Lindsey House, Chelsea. Improvements in the manufacture and application of elastic goods or fabrics.

611 W. E. Newton, Chancery-lane. Improvements in the manufacture of illuminating gas. (A communication.)

613 G. S. Dracopulo, Cardiff. A new apparatus for raising or forcing water, applicable to ships, mines, and other purposes.

615 R. and J. J. Bodmer, Newport, Monmouthshire, and L. R. Bodmer, Lansdowne-road, Notting Hill. Improvements in the manufacture of artificial stone, and in machinery to be employed therein.

Dated February 25, 1868.

617 H. Defries, Houndsditch, City, manufacturer. Improvements in the manufacture of opal or glass lamp and gas globes, chimneys and shades of every description.

621 E. T. Hughes, Chancery-lane. Improvements in the manufacture of hoop skirts. (A communication.)

623 E. Hutchinson, Darlington, Durham, iron manufacturer. Improvements in the construction of planing machines.

625 J. and W. Dobbs, Manchester, hatters. Improvements in the ventilation of hats and similar coverings for the head.

629 J. M'Leod, Renton, Dumbarton, engineer. Improvements in apparatus for washing yarns.

633 C. Pieper, Finsbury-square. Improvements in machinery for grinding or preparing wood for the manufacture of paper. (A communication.)

635 C. Pieper, Finsbury-square. Improvements in reaping machines.

637 A. M. Birchall, Preston, Lancashire, tobacco manufacturer. Improvements in the manufacture of twist tobacco, and the making of the same into rolls, and in the machinery or apparatus employed therein.

Dated February 26, 1868.

639 G. C. Mackrow, Orchard-yard, Blackwall, naval architect. Improvements in the construction of batteries for ships of war.

641 L. Pocock, Gordon-square, London. An improvement in bookbinding.

645 W. E. Gedge, Wellington-street, Strand. An improved machine intended to divide, break, or crush all substances capable of being triturated, more especially bones and horny substances of every kind, for converting them into manure. (A communication.)

647 A. V. Newton, Chancery-lane. Improvements in electro-magnetic apparatus. (A communication.)

649 F. Mittonette, Deepfields, Staffordshire, engineer. Improvements in furnace doors.

651 W. Dowell, Rhyl, Flintshire, whitesmith, and J. Dowell, Penmaenmawr, Carnarvonshire, ironmonger. Improvements in locks.

PATENTS APPLIED FOR WITH COMPLETE SPECIFICATIONS.

Dated February 27, 1868.

653 F. Wirth, Frankfort-on-Maine, Germany. Improvements in pedals and damping apparatus for pianofortes. (A communication.)

658 C. C. and W. T. Walker, Shropshire, engineers. Improvements in centre valves for gas purifiers and other apparatus.

Dated February 28, 1868.

674 J. G. Stidder, Hanover-street, Long-acre, engineer. Improvements in water-closets, lavatories, and urinals, and in regulating supplies for same by water valves.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the "London Gazette," March 10, 1868.

2988 W. E. Gedge. Nails or tacks. (A communication.)

3014 G. and E. Dorsett and J. B. Blythe. Burning gases.

3027 W. Payne and A. B. Fraser. Ships' pumps.

3028 J. de Silva. Compositions for coating the bottoms of ships.

3029 G. Smith. Marking boards used in the game of billiards.

3030 H. A. Bonneville. Machine for manufacturing paper bags. (A communication.)

3045 E. T. Hughes. Machines for twisting lines. (A communication.)

3047 W. Bishop and B. Burningham. Preventing effluvia entering tanks.

3049 W. P. Savage. Excavating soil.

3051 G. Davies. Preventing incrustation in steam boilers. (A communication.)

3052 W. H. A. Bowhay. Constructing horse ploughs.

3056 T. E. Symonds. Construction of ships.

3057 F. Piercy. Tinting photographs.

3062 R. Clegg. Pumps.

3064 W. S. Dixon. Producing a blue dye.

3069 W. R. Lake. Exhausting the air in vessels for food-preserving purposes. (A communication.)

3070 I. Kendrick. Steam boilers.

3080 S. Parr and A. Strong. Construction of buildings.

3083 W. Darcy. Fastening gates.

3086 W. E. Gedge. Hat cover. (A communication.)

3117 C. E. Brooman. Reckoning apparatus. (A communication.)

3118 E. C. Vine. Stays.

3119 A. M. Clark. Railway brakes. (A communication.)

3122 W. E. Newton. Steam boilers. (A communication.)

3124 A. M'Dougall. Apparatus for stirring solid substances.

3137 A. M. Clark. Pianofortes. (A communication.)

3140 T. J. Baker. Manufacturing wheat into flour.

3149 J. Wheeler. Gloves.

3151 T. Clark. Permanent way of railways.

3152 T. Blackburn. Looms for weaving.

3153 C. Anderson. Regulating the position of endless travelling webs.

3159 W. Inglis. Shaft couplings. (A communication.)

3163 W. Chippendale. Coupling railway carriages.

3166 S. Hall and M. Whittingham. Locks.

3169 J. Gresham. Giffard's injector.

3171 M. Rollason. Suspended gas lamps.

3177 J. H. W. and A. W. Biggs. Joining warp ends.

3191 F. L. de Gerbeth. Treating oils.

3195 H. A. Bonneville. Lubricating boxes. (A communication.)

3223 P. de Bavay. Attenuating the effect of shocks between engines or carriages composing a railway train.

3249 R. Holliday. Cleansing wool.

3306 R. Leighton and T. Kirksham. Sewing sheets of paper forming books.

3336 R. M. Letchford. Matches.

3376 T. S. Horn. Miners' safety lamps.

3433 J. Eckersley and D. Martin. Permanent way of railways.

3449 R. M. Letchford. Circular boxes.

3488 J. Rae and G. Miller. Railway wheels.

3668 J. Lightfoot. Printing certain textile fabrics.

3685 J. Goodfellow. Metallic pistons for steam cylinders.

168 N. H. Rolfe. Machinery for cutting laths.

326 E. T. Mainwaring. Bale or metallic tie.

357 C. E. Brooman. Steam valves. (A communication.)

438 W. T. Sugg. Valves.

540 W. Betts. Producing trade marks.

602 W. Krutzsch. Machines for washing clothes. (A communication.)

647 A. V. Newton. Electro-magnetic apparatus. (A communication.)

653 F. Wirth. Pedals for pianofortes. (A communication.)

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list, who have given notice of their intention to proceed, within twenty-one days from the date of the "Gazette" in which the notice appears, by leaving at the Commissioners' office, particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed March 6, 1868.

2533 S. Smith	2756 E. P. Alexander
2538 J. and T. Bayley	2761 J. L. Field
2544 E. J. C. Welch	2865 W. E. Newton
2559 J. H. Brown	2981 J. L. Norton
2564 J. Rae	3013 R. Carter
2567 J. Pottle	3305 H. James and E. Drewett
2580 W. F. Cooke	3389 C. Albisser
2584 J. Perrin	3457 W. A. Herring
2607 J. A. M'Kean	3490 J. Beatty
2653 W. E. Newton	3712 J. Novikow
2693 R. Wilson and J. Nuttall	80 T. Greenwood
2708 G. H. J. Simmons	198 W. R. Lake

Sealed March 10, 1868.

2314 A. M'Dougall	2641 W. Potts
2438 G. Haseltine	2724 J. E. H. Andrew
2583 J. Wilderspin	2728 A. M. Clark
2591 J. Reid	2750 I. Dimock
2595 J. M. Napier	2779 W. R. Lake
2596 S. Dalton	2788 G. Mellor
2597 W. Whitehead	3003 G. J. Gunther
2598 H. A. Bonneville	3092 W. Cooke and W. Francis
2602 H. A. Bordin	3207 J. D. Scally
2603 R. Canham	3302 W. G. M'Ivor
2609 G. F. Bradbury and T. Chadwick	33 W. H. Atkinson
2621 A. M. Clark	179 H. A. Bonneville
2623 W. W. Burdon	184 J. Davidson
2637 J. G. Willans	

PATENTS ON WHICH THE STAMP DUTY OF £50 HAS BEEN PAID.

585 S. Chatwood	648 J. Shanks
597 D. and J. Manwell	659 W. Clark
608 H. Taylor	660 J. T. Harris
615 W. E. Newton	662 R. G. Fisher
617 A. Akeroyd	665 W. D. Allen
619 C. F. Varley	668 G. F. Ansell
636 L. Perkins	669 V. Delperdange
637 A. E. A. Aubert and G. E. M. Gerard	699 J. Atkins
	718 L. Gantert
639 W. Clark	748 B. Lawrence
642 F. Tolhausen	790 R. J. Gatlin

PATENTS ON WHICH THE STAMP DUTY OF £100 HAS BEEN PAID.

THE

MECHANICS' MAGAZINE.

LONDON: FRIDAY, MARCH 20, 1868.

SUBURBAN RAILWAYS.

THE growth of the suburbs of the metropolis, and the almost total emigration of everybody to those localities after the hours of business, has necessitated the construction of special lines of railway for nearly the sole purpose of carrying them backwards and forwards. Of this description of line, the Metropolitan—commonly, but not quite fairly, termed the Underground—Railway, the Metropolitan Extension, and the North London, are the most prominent examples. No two could possibly form a greater contrast, with respect to the principle adopted in their construction, than the two former. The Metropolitan proper, from Farringdon-street Station to that at Edgware-road, is wholly beneath the surface of the ground, although not arched over continuously, while the extension from Grosvenor-road Station, which is built upon the Victoria Bridge, to Ludgate-hill terminus, is carried the entire distance upon arches and intermediate bridges. Apart from the question of land, the cost of which is so variable as to vitiate all comparative estimates, the relative economy of the two systems would be an interesting subject. The cost of the permanent way would also stand as a constant in the comparison. We should thus have the cuttings, tunnels, retaining walls, and over bridges of the low-level system balanced against the embankments, viaducts, and under-bridges of the high-level line. So far as the bridges are concerned, the advantage lies upon the side of the low-level principle, as an over-bridge, from the far less weight it has to carry, can be more economically constructed than an under one, which has to bear the maximum load that any bridge is ever subjected to. The test of a string of locomotives covering the span of a bridge, which is the maximum load supposed possible to be brought upon any railway structure, entails the employment of an amount of material and a weight of iron sufficient for a couple of ordinary over-bridges. Against this comparative saving upon the side of the low-level lines must be placed the items of tunnels and retaining walls, features altogether foreign to the other system. There are additional reasons for employing retaining walls, in the cuttings of a metropolitan line, over and above those influencing their adoption in other situations. To prevent landslips, the choking up of the way, and stoppage of traffic, are the principal reasons for building retaining walls in cuttings in the open country, but while this is also the case in the example we are considering, there is a more serious result attending a slip. It might entail not merely the interruption of the traffic, but by precipitating valuable property, in the shape of houses and offices, into the gulf, cause an enormous expenditure in the shape of damages and compensation.

Besides necessitating the construction of special suburban locomotive routes, the matutinal and nocturnal journeys to and from the City by the inhabitants of the environs, have caused a very considerable increase of traffic to the main lines running through suburbs affording eligible sites for building upon. Virtually, a regular metropolitan traffic has been developed upon these lines, of which, perhaps, the London and South-Western and the South-Eastern are the best examples. As a consequence of this augmentation to the existing traffic, and, in some instances, an establishment of it where previously there was little or none, those stations in proximity to the terminus where formerly trains rarely stopped, now possess a complete service of their own. This is, however, attended with disadvantages in other respects. Let us select a place—Acton, for instance, the first station upon the Great Western line. This locality is developing rapidly, and the Company has recently put up additional accommodation there. Assuming that only five trains per diem stopped there some years ago, and that in a few years to come it will be necessary to run a dozen, how is this increased service to be effectually carried out without detriment to the rest of the traffic? One plan would manifestly be to run a greater number of trains, and the other to cause more to stop on their outward and home journeys. It would, however, be impracticable to run a large number of trains upon a main line solely for the accommodation of places scarcely ten miles out of London, especially over the same pair of rails. The Metropolitan Extension has demonstrated the absolute necessity of laying down separate tracks for different systems of traffic by providing for the main line, and the Extension proper, distinct lines of way. This obviates the difficulty, which would otherwise have to be surmounted, of stopping main line fast trains at small stations, which would not merely cause a serious delay in the time of accomplishing a long journey, but would be a great and unwarranted inconvenience to passengers bound for distant destinations.

It has been long proved that the running of two descriptions of traffic over the same metals is not an economical method of working a line. The shunting of the slower trains to make way for the faster, the danger of collisions in consequence, and the thousand and one hazardous contingencies involved, which in numerous instances have culminated in lamentable catastrophes, bear witness to the unsoundness of such an arrangement. Stephenson is stated to have remarked that the time would come when there would be a separate line of way from London to Newcastle, purposely to bring coals to the metropolis, and, but a short time ago, it was seriously mooted whether the experiment would not be worth trying. It may probably be ultimately accomplished. The remark applies with full force to the carrying on of suburban traffic. There is no question but that whenever a locality in the vicinity of a large city which was formerly but little resorted to becomes thickly populated, and is capable, with the assistance of the adjacent neighbourhood, of constituting a considerable and permanent source of passenger traffic, it ought to have its wants of intercommunication adequately supplied. To effect this, additional lines of rails should be laid down connecting it with the metropolitan terminus. In fact, it should be considered as an individual metropolitan extension, and not as a portion of some gigantic main line. The two should have a distinct line of demarcation maintained between them. Upon the present Extension this arrangement is adhered to so rigidly that passengers starting from either the Victoria or Ludgate-hill termini are not permitted to travel by a main line train to a station upon the Extension route, although the train stops at it for the purpose of taking up. The argument justly is, that there is an abundance of Extension trains running between Victoria and Ludgate, and the main line trains are essentially intended for those travelling beyond the bounds of the metropolis, and that, therefore, their seats should not be occupied by others whose journey is confined to a couple of miles, and for whom there is ample accommodation provided elsewhere. A great obstacle to any of our existing main lines adopting the plan of laying down additional rails to meet the requirements of an increase of traffic is the enormous price of land. In some instances, as upon the London and North-Western, space has been gained here and there by cutting off the toe of the slopes and building dwarf walls, the usual method of gaining additional breadth of road when wanted. There is, however, a limit to this, and even to cutting away nearly the whole slope and constructing regular retaining walls, and at the last the extra space can only be obtained by the purchase of the adjoining land.

THE COST OF OUR SHIPS OF WAR.

THE frequency and persistency of Mr. Seely's motions and speeches in the House of Commons, coupled with occasional violent articles in the press, have tended to invest the question of the cost of our ships of war with an interest it would not otherwise have possessed. The public has been told from time to time, through the two sources above named, that the waste and general mismanagement in our Royal dockyards have been so great that it would, upon all considerations, be a wise policy to entirely confine to private firms the building of ships for our Royal Navy. Indeed, some speakers and writers have gone so far as to advocate the closing of our Royal dockyards, for every purpose, both in peace and in war, and to trust solely and absolutely to the resources of private shipbuilding firms for the construction and repair of our fleet. We need scarcely add that we are not ourselves prepared to go this length. It is a question which, like all others, has two sides, and we believe we shall best discharge our duty to our readers, and render service to the State, by examining impartially into the facts of the case, and drawing those conclusions which the facts alone justify.

We have before us the blue book ordered to be printed by the House of Commons, July 22, 1867, showing the expenses incurred on her Majesty's ships building, converting, repairing, fitting, &c., during the financial year 1865-66, being the last return published. In the first place, we may state that, by the direction of the Lords of the Admiralty, Alexander Glen Finlaison, Esq., actuary of the national debt, was requested—with the view of determining the amounts which should appear in the accounts to be presented to Parliament as the current estimated annual charge for pensions of officers and workmen—to reduce to a present annual charge, if possible, in the shape of a per centage on the present amount paid as salaries and wages, the deferred charge incurred by the pensions of dockyard officers and artificers. Mr. Finlaison's report is published in the return before us; it is as lucid as can be desired. From it we find that the number of established artificers on the books of the various dockyards is (or was) 9,486, and the sum annually paid them for wages £622,358, the average wages per man being £65 12s. 1d. per annum, and the average pension per man £33 2s. 11d. per annum. There are 214 officers promoted to salary from daily pay, to whom, in the aggregate, the sum paid is £42,865, the average salary per man being, therefore, £200 6s. per annum, and the average pension per man £117 10s. 4d. The class of officers who have been on salary for the whole period of their service comprises 233 persons, to whom, in the aggregate, is paid for salaries a sum of £63,186 per annum, the average salary per officer, therefore, being £283 6s. 10d., and the average pension £253 9s. 11d. per annum. Assembling the sums paid to the three different classes of recipients under the head of wages and salaries, and the sums computed to represent the increase of charge caused by the prospect of allowances in superannuation, Mr. Finlaison obtains the following general result:—

Digitized by Google

	Issue of wages and salaries.		Latent increase on account of superannuation allowances.
To artificers	£622,358	...	£43,565
To officers promoted from day pay.....	42,865	...	3,890
To officers on salaries whole period of service	63,186	...	5,045
TOTAL.....	£728,409	...	£52,500

It, therefore, appears that there is a latent addition to the total sum paid for wages and salaries equivalent in amount to a further charge of £52,500 per annum by reason of the prospective charge for pensions. This latent addition amounts accurately to £7 4s. 2d. per cent. (in decimals 7·2075); but owing to considerations which have to be taken into account for mortality and secession, it appears that, for ordinary purposes, the rate of enhancement given to the wages and salaries of all classes combined by the prospect of pension on retirement may be placed at 7 per cent. We have given these figures in order that our readers may know the result of a careful and elaborate examination of this subject by Mr Finlaison—the most eminent authority we have upon such matters.

We now come to the more important part of our subject. On reference to the published return before us, we find that ships built in our Royal dockyards are charged with a very large sum for "incidental expenses" and "establishment charges," a sum much larger than any that has to be borne by a contract-built ship. Of course, private shipbuilders, in estimating the amount at which they can tender for the building of a ship for the navy, have to make provision for establishment expenses, interest on plant, &c., but they have not to provide for such vast charges as are placed to the debit of ships building in our Government yards—charges amounting, in many instances, to 50 per cent. upon the actual cost of the ship. It scarcely seems possible that gentlemen possessing the least acquaintance with business generally, and accountantship in particular, should tolerate a system which charges a ship building at Sheerness, Portsmouth, or Chatham, with any portion of the cost incurred in keeping a ship in seaworthy and efficient condition at the other side of the world. It is, nevertheless, the fact that many thousands of pounds expended in our naval establishments at the Cape of Good Hope, Hong Kong, Sydney, and other ports (we have eleven naval establishments abroad) are charged to ships building, &c., in our home dockyards. We cannot see the reason or justice in making a ship building, repairing, or converting in our Royal dockyards bear a pro rata charge for the chemical branch of the service, the chapels, the schools, scholarships, Southsea Castle lighthouse, coaling and watering service at Portland breakwater, &c. At any rate, it must be evident that if such charges as these are added to the cost of our Government-built ships, any fair ground of comparison of cost between them and ships built in private yards does not exist.

We cannot within the scope of one article deal with this subject in the comprehensive manner it deserves, and we must, therefore, at present content ourselves with one or two illustrations in support of our views. From a long list of items we take the following:—"Harbour and dockyard gear—viz., cables, pendants, chains, swivels, bridles, and buoys, transporting hawsers, warps, and docking and launching rope gear." This item amounts at the home yards to £42,183; at our naval establishments abroad to £2,753, making a total charge of £44,936. Now, this amount includes expenses which in no way spring from the shipbuilding, converting, and repairing operations carried on in our dockyards. It is also evident that a ship built in a private yard bears no portion of this charge, although as soon as she is out of the hands of her builders she occupies her position in one of our harbours, and has the use of the aforesaid gear, and which has been charged to ships being either built, converted, or repaired in a Government yard. Other items include fire-engines, buckets, hose, and other gear connected therewith; also, waterworks. There are also charges for shipping of timber and stores to other yards at home and abroad; for landing, surveying, receiving, depositing, and issuing timber and stores; for the preservation of timber, boats, and other stores; for deterioration of the value of timber and stores, &c., &c. It will be seen that some of these items (and we have only mentioned a few out of many) are directly attributable to a State policy, and are no more chargeable to Government-built than to contract-built ships. The ships built in our Royal dockyards have also to bear the whole charge for experiments, the advantages resulting from which are equally available for private shipbuilders as for the Government service.

We will conclude with the following illustration of the effect of the system we complain of. The "Agincourt," built by Messrs. Laird, of Birkenhead, undocked on the 27th March, 1865, figures in the return before us as follows:—"Total expenditure to 24th March, 1866, exclusive of indirect charges," £451,596 11s. 4d.; "incidental expenses" and "establishment charges," £7,418. The "Bellerophon," built at Chatham, undocked 26th April, 1865, stands as follows:—"Total expenditure to 24th of March, 1866, exclusive of indirect charges," £353,682 16s. 4d.; "incidental expenses" and "establishment charges," £121,842: so that although the "Bellerophon" cost nearly £98,000 less than the "Agincourt," she is charged with £114,424, "incidental expenses" and "establishment charges" in excess of that ship. It is now many years since sundry red-hot reformers turned their attention to Admiralty account-keeping, but the result of their labours seems wretchedly unsatisfactory.

"ACCIDENTAL DEATH."

THE above two words comprise the almost stereotyped verdict of coroners' juries at the inquests held after fatal boiler explosions. Now, there are thousands besides ourselves who know and feel that this is, in nine cases out of ten, an insult to human understanding—in fact, a very farce. We have never lacked opportunity to point this out, and, further, to insist that fuller investigation by more competent witnesses should be enforced. We have, also, held that since there is such a lack of moral responsibility in the matter, there ought to be some steps taken to enforce a legal responsibility. A man at 15s. a week is set to drive an engine; from, what in him is excusable ignorance or carelessness, an explosion occurs, life is sacrificed, and a verdict of "accidental death" is returned. Another thickhead ties scraps of iron and brickbats to his safety-valve lever to get more work out of his boiler: a similar result follows, and a similar verdict is returned. A penny-wise and pound-foolish steam user buys up a cheap boiler: it bursts, kills someone—verdict as before. Another wiseacre never overworks his boiler, and so goes quietly on for years, brooking no interference, because he never works above a proper pressure. At last a seam gives out through corrosion, or some similar cause, down comes—or rather up goes—his roof: death follows, and verdict as before. And we could fill a page with such and many other cases of ignorance, carelessness, prejudice, and shortsightedness which pass unpunished, because of the irresponsibility attaching to the culpable parties.

Now, it is very obvious that since society cannot take care of itself, authority ought to step in and override moral obliquity. Our guns and our cables are proved; why not, then, our boilers? In other countries the Governments insist on this, and were we to do so it would be the first step towards remedying a very dangerous condition of matters. But this would not be enough. The conditions under which guns, cables, and boilers are used imply wear and tear, and of a hard and trying nature, too. Then, if the users are not competent to judge for themselves as to the soundness or unsoundness of their machines, and if a wholesale destruction of life and property is probable by their failure, surely it is time for authoritative intervention. But as there appears no disposition to take the question up in this form we must turn to another view of the case, if haply we may find some means of checking the evil in a different direction. Prevention is certainly better than cure, and there are hundreds who have the good sense to act out this adage in a practical way, by joining one of the boiler insurance associations, and having their boilers inspected periodically. But the frightful accidents which constantly occur from boilers "not under inspection," induces us to look around for a legal cure since there is no legalized system of prevention.

Working, then, in a circle, we again arrive at our starting point, coroners' inquests. And here the first thing we have to notice is the notoriously unsatisfactory evidence which is adduced on these occasions as to the cause of the sad catastrophes under investigation. We cannot help thinking that an important step towards the reduction of the number of steam boiler explosions would be accomplished if it were made compulsory on the part of coroners to call to their assistance competent scientific men. These witnesses should be experienced in the construction and working of steam boilers. They should examine the exploded boiler, and make a searching investigation into all the facts relating to the occurrence. They should prepare plans and detailed particulars, which should undergo the careful consideration of the jury. By this means the blame would be brought clearly home to the right party, and we hope the law would be found to provide a punishment proportionate to the merits of the case. It is but reasonable to infer that by the above course of proceeding we should have, in the first place, reliable evidence, and verdicts in accordance with stated facts. Were this so, boiler owners—knowing that in the event of an explosion occurring to their boilers, a searching investigation would be made—would exercise greater care and precaution in the purchase of their boilers, the selection of their attendants, and would adopt all the precautionary measures at their command in working. That we should then have greater immunity from such fatal occurrences is not a mere matter of speculation or conjecture, but an absolute certainty. One, too, proved over and over again by the returns of the boiler insurance companies, which tell the ever-constant tale of boilers saved from bursting, by timely examination on the one hand, and of the explosion of boilers not under inspection on the other.

We are very glad to be able to say that not only are we not alone in our views of the subject, but that these views are now finding expression in a quarter where they are likely to lead to a practical issue. We may write and write till we are tired, and still may fail to convince some who choose to hold a contrary opinion. But when it comes to publicly recording the unanimous opinion of such gentlemen as Mr. Fairbairn, Mr. Whitworth, Mr. McConnel, and others of the same stamp, the most supine and apathetic may be led to see that there is something of responsibility attaching to steam boiler ownership after all. In view of this, it was certainly with satisfaction that we noticed the resolution on this head, which was passed

Digitized by Google

at the annual general meeting of the Manchester Boiler Association, held at Manchester last week, under Mr. Fairbairn's presidency. The resolution, which was supported by Mr. Webster, the eminent Queen's counsel, sets forth:—"That investigations conducted by coroners, as to the cause of steam boiler explosions, are, as a rule, unsatisfactory, the evidence unsound, and the verdicts contrary to facts, in consequence of which the public are misled, and these disastrous occurrences allowed to continue with constant loss of life. Fuller investigation would prevent this, and it is, therefore, highly desirable that coroners should at all times avail themselves of competent and independent engineering assistance in conducting inquiries having reference to steam boiler explosions, and this meeting requests the Committee of Management to take such steps as they may find necessary to ensure this becoming the established practice."

We rejoice to see such a resolution emanating from such a body of men as were assembled at its passing, and we have now some hope that the subject will assume a definite and tangible form. It was some four years since discussed by the Society of Engineers whether it was not within their province to bring the subject under the notice of the Government upon public grounds. We think it was; and if the members are still of the same opinion, it is doubtless still open to them to aid in the movement by co-operating with the authors of the resolution. This will be the more easy when it is borne in mind that Mr. Fairbairn and Mr. Whitworth are enrolled amongst their honorary members. But however this may be, and from whatever quarter the movement may receive support, it may depend upon ours. We are strongly of opinion that. having been once set on foot, the question will not rest until satisfactory provision has been made for enabling coroners' juries to arrive at more just conclusions than they generally do, and to give occasionally a verdict somewhat the opposite of "accidental death."

ELECTRICAL COMMUNICATION IN TRAINS IN MOTION.

THE vexed and long-agitated question of communication in trains in motion has received a step in advance, by the report Colonel Yolland has just sent in to the Board of Trade upon "experiments recently made on various lines of railway in which some of the trains have been run wholly or partially fitted with different systems of electrical communication between passengers and the servants of railway companies in charge of those trains." By instructions issued from the Board of Trade, certain experiments were to be carried out with the view of testing again the feasibility of the various plans of passenger communication that had already been tried; in addition to the fitted trains already running on the London and South-Western and the South-Eastern Railways, trains on a different plan were fitted on the London and North-Western, and on Mr. Preece's system (the South-Western) on the Midland Railway. In order the better to test the working of these communications, instructions were issued that the trains should be started from the stopping stations by the rear guard using the communication to the head guard and driver, careful reports being made of the daily workings of the communication. In the document now before us, Colonel Yolland gives an exhaustive report of the various workings, of which we give some details, but, as some description of the different systems is necessary, we state simply, for the information of our readers, their various peculiarities, and the manner in which each resembles or differs from the others. The plans tried were Mr. Preece's on the South-Western and Midland, Mr. Walker's on the South-Eastern, and Mr. Martin's on the North-Western. They have each a single conducting wire running throughout the train; for extra safety, two couplings, fixed at one end to the carriage, are used by Preece and Martin, whilst Walker uses one movable coupling. Each system provides a bell with battery and signalling arrangement in the guards' vans, a signalling arrangement in the carriages, on the plan that the communication once made remains so until the advent of the guard; the principle in each is identical, but different in detail. Preece and Walker have bells on the engine—on the Midland a semaphore on the weather board was used—Martin has none. Walker alone uses an external visual signal to indicate the compartment or carriage from whence the alarm was raised. The three plans are worked identically on the same electrical system, that known as "current equilibrium," and first used on the South-Western, where it is used in its integrity, requiring no adjuncts, such as the switches in the vans as used on the South-Eastern and North-Western; they are not required, and must render the working more confused by introducing further complications, which, in this case, are unnecessary.

Current equilibrium may be simply stated. If an insulated wire be continued for any length, and at various points in it similar poles of equal batteries be connected, the opposite poles being to earth, it is evident that the current will be in equilibrium, that the batteries are inactive. Let any point of the insulated wire be put to earth, the batteries immediately start into activity, and can be made to act upon any bell, indicator, or other apparatus. We can thus easily understand the electrical system in trains, the batteries in the various vans connected to the insulated wire, and each compartment being a point where a mechanical arrangement is brought into play for putting that wire to earth, and causing an action on the bells in the guards' vans. This is the system which may be said to be the only true one for working trains electrically. On the North-Western the results are reported as satisfactory; the experiments commenced on January 8, with a train of two vans and seven carriages making twenty-five double journeys of 125¾ miles, representing a mileage of 6,287 miles. Three failures are spoken of, all being in the conducting wire, which had "been unnecessarily twisted and broken by porters in the act of taking off the electrical coupling wires." On the South-Western experiments were made with the up and down Exeter expresses on the system of Mr. Preece, which has the merit of being constantly in use on this line since May, 1865—nearly three years. These trains usually consisted of the fitted engine, two vans, and five carriages, the distance being 219¾ miles. Forty-eight double journeys were made, giving a mileage of 21,096 miles. Seven failures in starting signals are reported, but these are all satisfactorily accounted for—two are due to the bell being placed on the tender—blowing off steam preventing the driver from hearing it; four occurred at Exeter station on account of the train standing on turn-tables preventing the "earth" being made good; the remaining failure is supposed to be due to the guard making the signal improperly. These seven failures cannot be looked upon as due to the system itself, and practically are not failures at all. Colonel Yolland remarks, "I travelled by this train on the 19th inst., and found the communication complete to the guard." "I think these experiments must also be regarded as satisfactory."

On the Midland, the Leeds express was fitted up with the same system, with the difference of a semaphore on the engine instead of a bell; this train did not work so satisfactorily as the above: this is not to be wondered at when we consider the changes made in the journey. The train left King's Cross with the fitted engine, two vans, and six carriages, one of which was not fitted. At Trent, the train was broken up, the two vans, two fitted and one unfitted carriage going on to Leeds. At Chesterfield, two unfitted carriages were added on. At Normanton, one unfitted van was taken off, and the train arrived at Leeds with "two fitted and two unfitted carriages, two vans, and the engine fitted." On the up-journey the reverse would take place. It is to be wondered at that the communication acted as well as it did. This train ran thirty-four double journeys of 201 miles each way, giving a mileage of 13,668 miles. A good many failures took place, but they were most of them satisfactorily accounted for. Two were due to weak batteries—a fault that could not occur if trains were well looked after; the others were principally mechanical, and are due more to the way in which the train was fitted up, which was without Mr. Preece's supervision. The substitution of a visual signal, such as the semaphore, in the engine does not appear to have been a satisfactory change; the travelling inspector, who was told off to carefully watch this train, reports "there is no dependence upon the drivers observing this signal; many of the signals given have been missed by them. The men say that looking out and watching their engines occupies their attention so much that there is no dependence to be placed upon their seeing the signal."

On the South-Eastern three down and the three up corresponding trains were fitted on Mr. Walker's plan, and ran respectively 96, 116, and 112 journeys of 88 miles each journey, giving the following mileage—8,448, 10,208, and 9,886 miles. The trials of these trains were reported as being very satisfactory, eight failures being reported, besides "six others where the train was not fitted." The failures are accounted for by weak batteries or mechanical defects. A train running so short a distance, and with so very few stoppages, place these trials upon the most favourable footing, and we are rather surprised at hearing of any failure at all. The comparative statement of mileage of these trains would be—

	Miles Daily.
Midland, one train running	401
North-Western, one train running	251½
South-Eastern, three trains running	each 176
South-Western, two trains running	„ 219¾

With the exception of the South-Western all these trains made double journeys, stopping for some hours at the terminal station, being cleaned and made up again, and returning to their original departure station same day.

These trials may be looked upon generally as a trial of one electrical system worked with slightly different mechanical arrangements. The success of any one proves the correctness of the system, whilst the success of all three places it beyond doubt. In all these trains the communication was frequently tried from the various carriages, and in all cases the mechanical arrangements were found to be equally satisfactory.

Referring more particularly to these electrical experiments, Colonel Yolland remarks, "the more simple the means of communication provided, the better it will be. Visual signals outside each compartment of a carriage or on the engine are useless, and only serve to increase the cost of the apparatus. Electric bells to ring in the guards' vans and on the engine are all that can be necessary." Colonel Yolland considers that there are some differences which should be got rid of. He only mentions one—the use of a single coupling on the South-Eastern (the position of which he objects to), and the use of two on the other lines; two couplings are used to ensure a good electrical contact, and render

Digitized by Google

failure less likely. Another question is, should these couplings be entirely disconnected at both ends or remain a fixture at one end to the carriage. We certainly think the latter the more approved method, and prefer using two couplings to one. This is a point there should be unanimity in. The manner of coupling on every line should be the same, for then a carriage would always be able to work in connection with foreign stock. No mode of communication will, in his opinion, be considered efficient which does not provide that a signal shall be given to the driver in the event of a train breaking away, and this can, he says, be effected with the electric apparatus. Many inventions were shown to him for carrying out the required objects, but he has declined expressing an opinion upon any that have not been in practical working on a line. As regards the possibility of establishing and maintaining electric communication throughout the entire length of a railway train, he thinks it is impossible to doubt that it can be done; but in order to keep such a system in order, it will be necessary that by starting trains and frequent signalling, it should be so worked as to be always in order, for fear that from disuse, it may, when required, be found wanting.

We are glad to find that our own opinions on this subject are so fully borne out, not only as to the practicability, but also to the necessity of such a communication, of both of which Colonel Yolland is thoroughly persuaded. Colonel Yolland considers that the question for decision is, shall railway companies be compelled by legislative enactment to provide the means of communication in trains—the decision pending on the questions, "Is such communication necessary, in order to provide for the public safety? Is it practicable?" For nearly three years the system of the South-Western has been working successfully; that fact is sufficient answer to the second question. As for the first, we certainly consider that for express trains and trains for long journeys, such a communication is necessary, and we should be glad to see some law passed rendering it compulsory.

PROTECTION OF THE EYES OF METAL WORKERS.

DR. HERMANN COHN, of Breslau, an oculist of some standing in the medical world, who is particularly well known by his examination of the eyes of 10,000 school children, has recently occupied himself with statistically ascertaining the effect which the occupation of metal workers has upon their eyes. The results he obtained by examining 1,283 factory workmen of Breslau are of the utmost interest for both masters and men in this branch of industry, and are worthy of a short abstract from the original paper, published in a medical journal, the "Berliner Klinische Wochenschrift." Although his range of observation was necessarily very limited, inferences on other similar branches are easily made. Dr. Cohn examined the workmen of six engineering establishments, whom he thus classifies:—599 fitters, 386 blacksmiths, 129 turners, 35 drillers, 13 planers, 27 enginewrights, 5 screwers, 15 boilermakers, 69 foundrymen, 8 cleaners of castings—altogether, 1,283. He did not include any labourers in his examinations, because their occupation is too shifting, and, therefore, he confined himself to mechanics with a constant occupation of the same character. About 90 per cent. of these men declared that their eyes had often been struck by small chips of iron, turnings, borings, or filings, which had been removed by some of their fellow-workmen. In every workshop there is a man or two who have acquired by long practice a remarkable proficiency in removing foreign bodies from the cornea. All those minor accidents were excluded by Dr. Cohn, and all the following figures refer only to such accidents of the eyes as required medical aid, and caused, for the most part, an interruption of work. Of the 1,283 workmen examined there had been 633—that is, 49 per cent.—under medical treatment for accidents caused to their eyes by metal chips, &c., and this on an average twice over, the number of accidents to the eyes being 1,231—that is, 96 per cent. of 1,283. The cleaners of castings seem to be most exposed to such accidents—87 per cent.; then come the enginewrights, 83 per cent.; turners, 69 per cent.; drillers, 54 per cent.; boilermakers, 53 per cent.; fitters, 49 per cent.; planers, 46 per cent.; blacksmiths, 44 per cent.; foundrymen, 26 per cent.; screwers, 20 per cent. Out of the 633 wounded men, 354 were soon relieved by medical treatment; but 279 required more or less time before their eyes were cured, and they consequently had to stay from work all this time. The whole time lost in this way amounted to 4,726 working days—that is, on an average, 17 days for each wounded man. The eye wounds of drillers, cleaners of castings, and turners, were soonest healed (four to ten days); next come planers, screwers, enginewrights, fitters, and blacksmiths; foundrymen and boilermakers seem to be exposed to the most dangerous eye-wounds, requiring from 40 to 47 days for curing. Out of the 1,231 eye-wounds, 1,172 were completely cured, 38 = 3 per cent. were not completely, and 21 = 2 per cent. not at all cured. This means that of 1,000 metal workers, 28 lose part of their seeing power, and 16 the whole use of one eye in consequence of their occupation.

It would not be much to the purpose in this place to follow Dr. Cohn in the medical detail of the different wounds, and their effect on the eye; only so much may be mentioned that the wounds of blacksmiths and fitters are, as a rule, of a much more dangerous character than those of other men, and that they lose one of their eyes much oftener than these. This is no matter of surprise, since their eyes are mostly hurt by red-hot metal. Now, the question arises—Cannot this danger to the eyes of metal workers be avoided by their using protecting spectacles? Of the men examined by Dr. Cohn, only 21 used blue conservation spectacles, in consequence of previously received wounds; and 31 used ordinary convex glasses, owing to their being far-sighted. Not one used protecting glasses. When asked why they did not take more care of the most noble organ of their body, the men always replied, "Spectacles are too easily broken," "They are too heavy, and they are too dear." These objections are unquestionably valid, and caused Dr. Cohn to consider what other preventive means might be resorted to against those too frequent accidents to the eyes of metal workers. There happens to be a manufactory of objects of mica, such as lamp chimneys, &c., at Breslau, where Dr. Cohn resides, and thus mica suggested itself to him for his purpose. He caused Mr. Raphael, the proprietor of the just-mentioned establishment, to try experiments with manufacturing protecting spectacles from mica, and those experiments were crowned with perfect success. They seem to have completely solved the above-named difficulties. The mica spectacle glasses are curved somewhat in the shape of watch glasses; they not only protect the eye in front, but their brass frames fit closely on the osseous circle round the eye sockets, so that no chips can enter the eye from any part, and still the eyelashes do not touch the glasses. The frame is made of thin brass wire, which can easily be bent by hand into any shape. As hinge-joints would have caused too much expense, the side parts are soldered on to the frame. The thickness of the mica is one-half millimetre. Only the purest kind of mica being used for this purpose, these spectacles are just as transparent as real glass ones. They impart, to be sure, a slight pale grey tint to the objects, but they do not in the least weaken the optic power of the eye. For blacksmiths and foundrymen, such a grey tint is rather an improvement, and for other metal workers it is not in the least objectionable. Now, these mica spectacles, besides protecting the whole eye, have the following advantages:—First, they cannot be broken; heavy blows with a sledge-hammer only squeeze them flat, without breaking the glasses. They may be thrown to the ground with full force without being damaged in the least. Red-hot metal poured on the mica does not make any impression on it. The shower of pointed particles of iron which issues from lathes, &c., only rebounds from the perfectly elastic mica glasses. Secondly, Mica spectacles are almost twice as light as glass spectacles; a pair of French watch-glass-shaped spectacles weighs 13·9 grammes; mica spectacles only 7·5 grammes. Thirdly, mica spectacles keep the eyes of the workmen cool, mica being a very bad conductor of heat. Fourthly, mica spectacles are very much cheaper than glass spectacles, especially watch-glass spectacles, which are the only ones that protect the whole eye. The mica spectacles are sold at Breslau for about eightpence English money a-piece. They would be, of course, a few pence dearer in this country, as carriage, duty, commission, &c., would add to the expense. But, at all events, their cost would be exceedingly trifling when compared with the very serious expense, loss of time, and pain that are caused to iron workers by the frequent accidents to their eyes. No doubt, Mr. Raphael will soon establish an agency for the sale of mica spectacles in this country, and we shall then hear more about them. As it is, we strongly recommend our metal workers to look into so important a matter.

PREPARATIONS TO PHOTOGRAPH THE GREAT ECLIPSE.

IN the middle of August next there will be a total eclipse of the sun, of almost the longest possible duration, and visible in India. The Indian Government has, consequently, made preparations to obtain a photographic record of the phenomena presented during the obscuration, in order to gain still further information as to the physical constitution of the sun. Major Tennant and a party of sappers have spent some days at the observatory of Mr. Warren De La Rue, at Cranford, in order to perfect themselves in astronomical photography before they attempt the work before them next August in India. The telescope to be employed upon the occasion is now in course of construction by Mr. Browning, F.R.A.S., and it is almost an exact copy of the one used at Cranford by Mr. Warren De La Rue. The mirror, of silvered glass, is 5ft. 9in. in focus, and the image of the sun—which it will throw out at the side of the tube, because of the interposition of a plane mirror, as in the Newtonian telescope—will be a little more than 1in. in diameter. This small size of image of course gives an enormous concentration of light, but when the pictures are taken the dark body of the moon will obscure all but the prominences upon the sun, thereby reducing the overaction which might otherwise be expected. The process to be adopted is that hitherto used with so much success by Mr. De La Rue in lunar photography. The collodion will be salted with iodine of cadmium only, excited in a 30gr. or 35gr. bath, developed with pyrogallic and acetic acids, and fixed with hyposulphite of soda. The totality will last nearly five minutes, in which time it is expected that six negatives will be obtained. Each plate will be enclosed in a metallic dark slide, and rest against ledges of chemically pure silver, the latter metal giving security against stains. Great

Digitized by Google

care has been taken by means of micrometer wires and other devices to secure the accurate "register" of each plate, and to make the pictures comparable one with the other in the matter of measurements. No attempt will be made to magnify the image of the sun by the interposition of lenses between the mirror and the photographic plate, because this plan would diminish the intensity of the light, lengthen the exposures, and interpose possible sources of imperfection in the matter of focussing.

By long experience lunar photography has been brought to a high degree of perfection, and the processes adopted are sound in principle, both theoretically and practically. Solar photography is open to a little more criticism, because every practical photographer knows that bromides are much better adapted for taking brilliantly-lighted objects than iodides. It is only within the last few months that the right method of working with bromide of cadmium only, and no iodide, has been discovered. In the early days of photography it was thought that bromides alone were useless in collodion, because they gave nothing but thin grey images, devoid of pictorial beauty, and the mistaken opinion was caused by the fact that experimentalists worked with bromides in conjunction with the same baths and solutions found so successful with iodides.

The fact of the matter is, that a bromized collodion must be treated in an altogether different manner to give the best results. The silver bath should be double the ordinary strength, that is to say, sixty or seventy grains to the ounce, and the collodion, containing ten or twelve grains of bromide of cadmium to the ounce, should be excited in it for about ten minutes. When taken out, the solution upon the plate will be much too strong for clean development: hence the plate should be dipped in a second nitrate bath, weaker than the first and very pure, after which it is ready for exposure. This second bath may with advantage consist of the ordinary preservative used in the glycerine process, as the purified organic matter contained therein has a beneficial effect on the pictorial qualities of bromized plates. The bromized collodion works best a month or two after mixing, and sometimes the addition of a minor proportion of iodized collodion is an advantage. A pyrogallic acid developer is probably the best under ordinary circumstances, though when the organic preservative is used, the pictures given by iron development are so delicate that it is doubtful whether they would show symptoms of granulation under the microscope.

In photographing the great Indian eclipse, it is quite evident that the operators must not be allowed to try novel photographic experiments, yet the views here set forth demand serious consideration. It is an established fact that bromides will photograph details in brilliantly lighted objects, which iodides are incompetent to produce, showing in place thereof a dark patchy blank. Bromized glycerine plates will secure good pictures of brilliantly-lighted fleecy clouds after an exposure long enough to utterly spoil the same clouds upon an iodized plate. Solarization may in all cases be checked by a trace of citric acid in the developer, yet this acid must be added very sparingly, because an excess of it lengthens exposure. For lunar, stellar, and planetary photography, we acknowledge, upon theoretical grounds, that the use of iodized collodion is right in principle, but in the matter of the intense light incidental to solar photography, the presumptions are very strong in favour of bromides. When a commercial photographer wishes to secure detail in a brilliantly-lighted white object, his rule is to use a "highly bromized collodion, slight over exposure, and slight under development." Till experiment shall prove the contrary, it is difficult to see why the same principles should not hold good in solar photography. At all events, no stone should be left unturned in the attempt to bring solar photography to such perfection that the plates will take impressions of every feature presented by the sun, and set at rest the dispute whether interlacings, like "willow leaves," are ever seen upon its disc, since one set of observers says they are sometimes to be seen, and other observers ascribe the alleged phenomena to imagination. Moreover, bromides are sensitive to more of the rays of the spectrum than iodides, so are calculated to include a slightly greater range of actinic phenomena. An experienced practical photographer would be a valuable addition to the Indian expedition.

NOTES ON RECENT SCIENTIFIC DISCOVERIES AND THEIR PRACTICAL APPLICATIONS.

TO SEPARATE BUTYRIC ACID, AND OBTAIN PINEAPPLE ESSENCE FROM GLYCERINE—A NEW MODE OF ORNAMENTING PAPER—A PROCESS FOR SILVERING HOOKS AND EYES MADE OF IRON WIRE.—THE PHYSICAL PROPERTIES OF PETROLEUM—A DISCOVERY IN MAGNETISM—NEW CHEMICAL DISCOVERIES.

GLYCERINE separated from most fats is contaminated with butyric acid. Its pre , according to H. Perutz, may easily be recognized by distilling the glycerine with some sulphuric acid and alcohol, by which means butyric ether will be obtained and at once identified by the pine-apple odour. On the large scale, the butyric acid may be separated by filtering the glycerine through animal charcoal. The acid will be retained in combination with lime, and the butyrate of lime may afterwards be extracted by alcohol, and the solution, on distillation with sulphuric acid, will give pineapple essence in commercial quantities at a cheap rate; or the butyrate of lime may be decomposed by the addition of oxalic acid, and the butyric acid purified by distillation.

Puscher gives a simple process for ornamenting paper with silky crystals, an improvement on the method we published last year, in which sugar of lead was employed. He now recommends sulphate of magnesia to be used. He dissolves six parts by weight of Epsom salts and six parts of British gum in six parts of water, adds a small quantity of glycerine, and boils the liquid for a moment. He then strains the solution and allows it to cool a little. Before it is quite cold he spreads it with a camel's hair brush upon paper previously done over with a thin solution of glue or gelatine. As the paper so prepared dries it becomes covered with a beautiful crystalline surface. The crystals are long or small according to the strength of the solutions, and rapidity with which the paper is dried. To obtain variegated crystals, the solution may be coloured with various aniline colours, and the paper must be prepared with a mixture of equal parts of white of egg and water instead of the gelatine solution. Paper so ornamented, it is said, may be glazed by passing it between rollers or putting it under a press. In consequence of the presence of the glycerine, the paper does not completely dry, and may be printed upon by the lithographic process without being moistened. The process is recommended for ornamenting envelopes, dinner, pattern, and visiting cards, and also playing cards. One perhaps useful application remains to be noticed. A solution prepared with one-third the quantity of gum before mentioned, and with no glycerine, may be applied to a lithographic stone, and a copy of the crystallization obtained may be transferred to another stone by the usual lithographic process. A transfer may be made from this to three or four other working stones, from which many thousands of impressions of the crystals may be taken. The author recommends the impressions from these stones on yellow paper as a back ground for bank notes, for as no two exactly similar crystallizations are likely to be obtained it will be impossible to commit a forgery. The yellow paper is, of course, recommended to prevent a copy being made by photography.

A process for silvering hooks and eyes made of iron wire has been patented in Bavaria by Toderer. Such hooks and eyes are first suspended by means of zinc in a copper vessel containing dilute sulphuric acid until the iron shows a clean bright surface. They are then well rinsed with water, and afterwards placed in a bath of a mixed solution of sulphate of zinc, sulphate of copper, and cyanide of potassium. Here they remain until they receive a bright coating of brass. They are lastly transferred to a bath of nitrate of silver, cyanide of potassium, and sulphate of soda, in which they quickly receive a coating silver. This new manufacture, it is said in "Dingler's Journal," answers all requirements. To us it looks complicated, and the result improbable, but we give it in case any of our readers should like to try the experiment.

The physical properties and calorific power of American petroleum have been investigated by M. Henry Deville, who has just communicated his results to the Academy of Sciences. We shall return to the memoir for some useful facts it contains, and now only notice one important point established. M. Deville shows that Pennsylvanian petroleum increases in bulk by one hundredth of its volume for every 10deg. Centigrade of heat. This, the author points out, is a fact to be considered when storing petroleum for fuel in steam vessels, where it will necessarily be exposed to a higher temperature. Space should be left in the casks to allow of this expansion, or they may burst and give rise to an explosion. Another source of danger on board ship—and, as dealers and speculators in the article well know, a cause of great loss—is the power petroleum has of penetrating wood. The loss and the danger, however, may both be obviated by paying over the interior of the casks with a strong solution of glue or albumen. This, when dry, forms a coating impermeable to the oil. There are other solutions used for the same purpose, but nothing, we believe, answers better than glue, although M. Garnier states that he can send petroleum about safely in paper bags saturated with a preparation of his invention. M. Deville makes the recommendation quite unnecessarily we think, that the lighter oils should be distilled off when the petroleum is intended for fuel.

M. Gerard has discovered a very curious fact. If a metallic ring made of wire, the diameter of which varies regularly, so that at one side of the ring it is very thin, and at the other side relatively very thick, be suspended over an electro-magnet, it will begin to revolve. The author sees in this fact the germs of a new system of electric telegraphy, for the details of which we wait.

The indefatigable Dr. Hofmann announces the discovery of a new acid which bears the same relation to napthaline that acetic acid bears to marsh gas. A few weeks ago the same eminent chemist communicated to the Royal Society the discovery of "the mustard oil of the ethyl series."

HAVRE INTERNATIONAL MARITIME EXHIBITION.

THIS exhibition, which is to open on the 1st June, proposes features of special attraction for the shipbuilders and engineers from the opportunity it affords of bringing prominently before a large public at a great shipping port all new inventions and improvements calculated to be useful in navigation. The classes embrace everything relating to the construction, fitting, preservation, and navigation of ships and steam vessels. Models of lighthouses, port and harbour constructions, signals, diving and salvage apparatus, appliances for loading and unloading vessels. Indeed, no matter that can add to the completeness and comfort of a ship, whether for the purposes of war, common passenger trade, or fishing operation, seem to have been omitted in the programme published by the committee. The promises of support and contributions from the principal maritime nations of Europe and America, holds out the prospect of its being, indeed, an international display. There can be little doubt that special exhibitions are more likely to be generally beneficial than those great 'omnium gatherums where exhibits are swamped from the multiplicity of objects shown, rendering it impossible to form a just appreciation of merit. English exhibitors who have not already secured space have little time to lose, and should send in their applications forthwith to the concessionaries for the United Kingdom, Messrs. J. M. Johnson and Sons, of Castle-street, Holborn.

THE tolls received on the Chelsea-bridge in the financial year 1866-67 amounted to £6,014. The year's expenses were £2,398. The result was that the balance in the hands of the Paymaster-General was raised to £10,892.

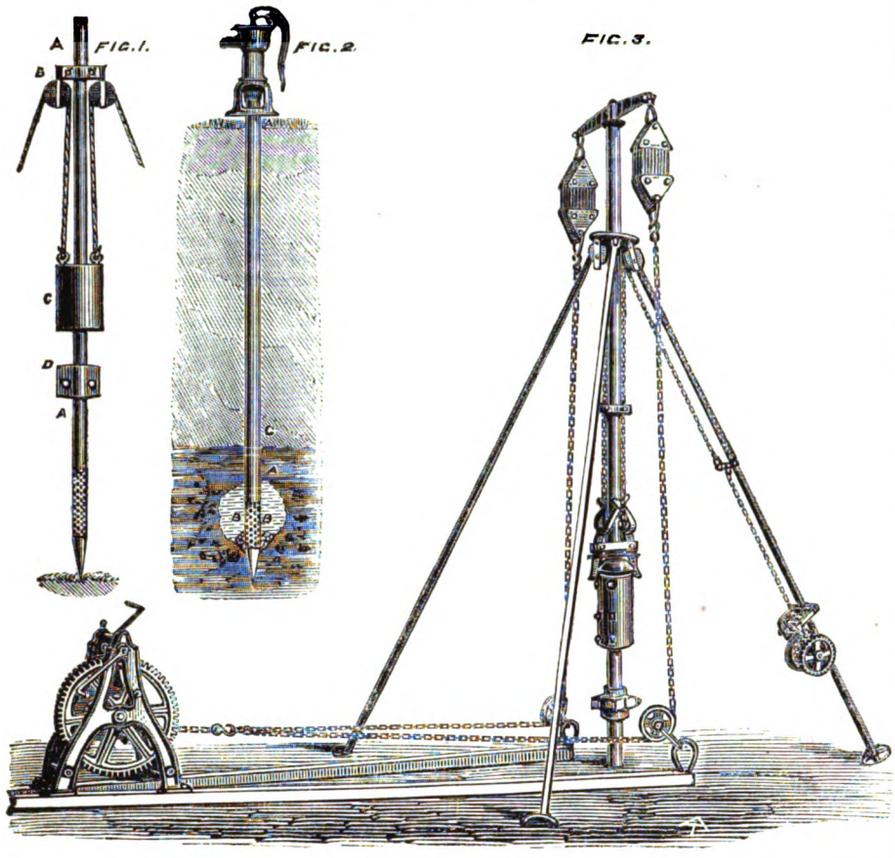
THE AMERICAN TUBE WELL.

BY MR. J. L. NORTON.



THE AMERICAN TUBE WELL.

SOME three months since we noticed in general terms the very ingenious and practical invention of Mr. J. L. Norton, of No. 38, Belle Sauvage-yard, Ludgate-hill, for obtaining a speedy supply of water. It is with pleasure that we now again refer to the subject, for the purpose of describing it in detail and of recording some highly successful experiments which we witnessed on Saturday last. The invention in question is generally known as the American tube well, and it has earned a substantial reputation from its successful working in the Abyssinian operations. First, to describe the tube well, we will refer our readers to fig. 1 of our engraving, where the lower portion is seen in elevation. The tube well is made of wrought iron of various lengths and diameters, the ends being screwed. The lower part is perforated for about 2ft. from the bottom, and the driving point is of steel. The tube well A is driven into the ground by a monkey C, suspended over pulleys attached to the clamp B, from which it is worked by ropes. The monkey falls on the clamp D, which is made in two parts bolted together on the tube. The insides of each of the clamps are serrated so that they take a bite into the tube, and are thereby prevented from slipping. When in the course of driving the clamp D reaches the ground level, it is unscrewed and raised to a higher position, and the operation of driving is resumed, the monkey clamp being also raised. This is repeated until the well is driven the necessary distance to secure a plentiful supply of water, which is ascertained by dropping a leaded line down the tube. With 5ft. or 6ft. of water in the tube or well, an abundant supply may always be depended on, though it may be driven further if thought advisable, care being taken not to drive through and out of the water stratum. As soon as the well is driven the required depth a cleansing pump is attached, and by pumping for a short time the sand, fine gravel, and dirt around the perforated end of the tube is pumped up and a closed reservoir is formed. The tube well as sunk, and having the pump fixed ready for working, is shown at fig. 2, where B shows the reservoir, and C the line of the water-holding stratum. The first water is accompanied by sand and gravel, &c., and when it runs free from these the cleansing pump is replaced by a permanent pump, which completes the well and fits it for use. Should any stoppage occur by reason of the tube having been sunk through clay, or from any cause, water is forced down the tube under any required pressure and clears a ready passage to the water-bearing stratum.

Having described the tube well, we will now direct attention to the experiments which were made last Saturday in a field at Thames Ditton. The little Abyssinian tube was the first point of interest. This tube well is 1¼in. in diameter, and is worked by two men, with a 70lb. monkey, driven over pulleys attached to a light iron tripod, as at fig. 3. This obviates the necessity of shifting the upper clamp, and insures a direct vertical blow. In the present instance, the tube was driven 14ft. into the earth—a gravelly soil—in 17min., when it was found by sounding that water was reached, there being about 5ft. in the well. The cleansing pump was then put on, and in 2min. more, or 19min. from the commencement of the operation, water was pumped. Having demonstrated this point, it was proposed to show how easily the tube well could be removed. By means of a lever the well was drawn up and laid upon the field in a minute and a quarter. In another part of the field a 2-inch pipe was driven 30ft. into the soil, in a proportionately short time water being as readily obtained. Further on was a larger tube of 3in. in diameter, which had been driven to a depth of 14ft., and in which the water rose to a height of 5ft. 6in. The operation of sinking this large tube derived additional interest from the application of Mr. Norton's patent accumulator in the process. This special feature is seen at fig. 3, which represents the method of driving the 3-inch pipe by the aid of the accumulator. This apparatus consists of a crosshead, which is kept in place on top of the tube, and to each end of which is attached an apparatus, formed of two sets of triangular iron plates, bolted through at various points, but kept about half an inch apart. These iron frames are connected by a series of strong india-rubber bands which pass over the connecting bolts in each set. From the bottom of each accumulator a chain passes away to the crab, which is turned sufficiently to bring a pressure on the top of the tube. A constant downward pressure on the pipe of ten, fifteen, or twenty tons, as the case may require, is thus secured. By this highly ingenious arrangement the inertia or rebound of the pipe, when the blow from the monkey comes upon it, is effectually overcome. This result was practically demonstrated on Saturday by the rapidity with which a tube of the comparatively large diameter of 3in. was sunk. The several experiments, which were attended by a number of scientific gentlemen, were a decided success, and showed that tubes of large as well as of small diameters could be sunk with facility and certainty.

The general merits of this system of well sinking are known and admitted, having been proved in all parts of the country, and having been brought prominently under notice by the operations in Abyssinia. Our notice, however, would hardly be complete did we not draw attention to its numerous advantages, and make some deductions from Saturday's trials. But, first, let us say that the inventor does not pretend that the tube well can produce water under any conditions, or where that element does not exist. It is simply an easy, economical, and efficient system for obtaining water in water-holding strata, and as such our experience of its working enables us to recommend it with confidence. The invention facilitates the operations of testing for and obtaining water quicker, cheaper, and purer than by the ordinary tedious and expensive process. In strata where water varies very much in its quality at various depths, instances have been met with in which large sums of money have been spent in attempting to sink curbs or rings in quicksands to form a well, and have failed, where, on the patent tube plan, the most successful results have followed. The difficulty of drawing water from a quicksand is admirably overcome by a filter, which is placed in the perforated end of the tube well. This filter is thus constructed. Within the perforated end of the tube is an inner tube, also perforated, and around which is coiled a sheet of wire gauze, which fills the annular space between the two tubes. By this simple expedient wells are successfully sunk in soils such as the Bagshot sand. In a sanitary point of view, too, the tube well must prove valuable, inasmuch as it frequently happens in sinking a well on the old principle that a stratum of bad water has to be gone through, and which it is impossible to keep out, whilst, under the tube system, no surface or other water can filter through. Water obtained by this plan is thus free from all atmospheric influences, surface drainage, sewage, or cesspool leakage. The conclusions to be drawn from the recent experiments are, that the operation of sinking the tube wells is simple, cleanly, effected without disturbing the ground, and may be performed by unskilled labour. Should the sinker be disappointed in finding water the well may easily be withdrawn and driven in another place, without any loss except that of a little time and labour. On the other hand, especially with a little knowledge of the locality and strata, or if judgment be displayed, should water be present, it will assuredly be found and rendered available more quickly by the tube well system than by any other known means.

TRIALS OF ARMOUR PLATES.

SOME trials of armour plates, from Messrs. Cammell and Co.'s, Cyclops Steel Works, Sheffield, took place last week on board the "Thunderer." They comprised an 8in. plate, for the colonial turret ship "Cerberus," building by the Palmer Shipbuilding Company, Jarrow-on-Tyne, and a 6in. plate for the second-class armoured iron frigate "Audacious," building by Messrs. Napier, of Glasgow. The 8in. plate was 12ft. in length, by 3ft. 6in. in width, and was struck by nine shots within an area of 32in. vertical, and 18½in. longitudinal measurement. The maximum indent was 1·6in., and the minimum 1·5in. Two shots fell on the edge of a bolt without doing any injury, and the result of the total pounding only brought out slight surface cracks within the area of the indentations. On examination, the plate exhibited favourable results, the greatest amount of bulge on its reverse side being only 2⅜in., all the openings in the metal being longitudinal. The 6in. plate measured 16ft. 7in. by 3ft. 8in., and was struck by five shots, within an area of 19in. square. No damage on the obverse side of the plate was done outside the area of the shot indentations. The maximum indentation was 2·1in., and the minimum 1·9in. On examination, this plate was found to have only longitudinal openings on the reverse side, but although undoubtedly one of good character, the plate was softer in metal than the average of plates are found on trial, the extent of the bulge being 3⅞in. On the whole, the plates exhibited favourable results.

RAILWAYS AND THEIR MANAGEMENT.

A PAPER was read at the meeting of the Society of Arts, on Wednesday night, on the subject of Railways and their Management, by Mr. Robert F. Fairlie, C.E. The Marquis of Clanricarde presided, and there was a numerous attendance of members and their friends. The paper commenced by showing that at least 20 per cent. of existing railway investments are unproductive, but that the whole might be rendered remunerative by an adequate system of working and management. In this respect Ireland furnishes an opportunity for effectively developing the principles by which such results could be secured. An imperial guarantee of 3½ per cent., which would not involve the State in a liability of more than £100,000 per annum, would evoke from private sources sufficient capital to construct nearly one thousand additional miles of railway in Ireland, by which its most distant points would be connected with the best markets for their produce. And this guarantee would not remain a burden upon the State for many years, provided the outlay was judiciously made, and the management adapted to the actual requirements of each locality. At present, Ireland, with less than 2,000 miles of railway, had between thirty and forty independent boards of direction. The consequence was that fares were unnaturally high, and the management without proper combinations for the public benefit. Experience had shown that concentration of control did not involve monopoly, and that it was indispensable to successful administration, as well as to remunerative action. Referring to the English lines, Mr. Fairlie expressed his strong dissent from the practice of expending capital upon palatial stations; and observed that, in future, attention must be directed to the economy of capital. As a general rule, the natural configuration of a country would permit the working of railways upon the principle of surface construction, securing public safety and convenience on the one hand, and on the other a fair return for the capital invested. Capital accounts must be closed, which he contended might be effected without difficulty, if the administration was based upon sound principles. Charges for renewals of road, stock, and stations ought to be placed against revenue; but every new work of an original kind ought to be provided for by a special capital, which capital should be redeemable out of the surplus annual revenue. He strongly condemned the raising of capital at a discount as the worst possible mode of raising money, because its simple effect was to increase all the expenses attending the line, and because it was impossible such a mode of raising money could improve railway credit. The more rational way was to raise the money required by loan, and to redeem the debt by half-yearly payments set aside from profits.

Mr. Fairlie next showed that revenues might be increased concurrently with a large reduction of working expenses. Railway managers seldom took the trouble of ascertaing the returns from each train, compared with its expenses; but he would recommend a debtor and creditor account to be kept of every train run, as the only safe means of ascertaining profits and loss. The gross earnings of the London and North-Western Railway in 1866, were at the rate of 5s. per train per mile for passengers, and 6s. 3¾d. per mile for merchandize; but he contended that the earnings ought to be in proportion to the speed. For passenger trains at twenty miles speed per hour the gross earnings ought not to be less than 7s. 6d. per mile; 10s. for thirty miles; 14s. for forty miles; 20s. for fifty miles; and 30s. for sixty miles. It was absurd for companies to make such slight differences in their charges for high and low speeds, seeing that the cost of working increased in proportion to velocity. The gross earnings of the Brighton line were under 4s. 10d. per mile, though many of their express trains must realize not less than £3 per mile. It was clear, therefore, that a large number of trains on this line must be run at a loss. He counselled, in all cases, the abandonment of non-paying trains, believing that the public would not expect the companies to carry them without a proper return. As to expenditure, he strongly urged the disadvantage of overweighting trains by the use, for example, of tenders, observing that generally they were 200 per cent. in excess of the paying load carried. The load of fuel and water carried by the tender should be made available to increase the power and efficiency of the engine itself. At this moment he had at work on a Welsh railway engines without tenders, where the fuel and water were in the highest degree conducive to the power, economy, and safety of the engine. The weight was distributed equally upon a large number of wheels, thus increasing their adhesion upon the rails, while the weight on each wheel was reduced in proportion. Here was the basis of an entire revolution in our locomotive arrangements, which would be attended with enormous economy. It would reduce the proportion of dead weight to paying loan; and, applying the same principle to passenger traffic, he showed, by calculations, that a saving might be effected equal to a dividend of over 3 per cent. per annum. Ordinary omnibuses weighed about one ton, and carried twenty-eight passengers, or two tons, thus giving two tons of paying to one ton of unpaying load; but the Metropolitan Railway on its present system, carried only one ton of paying load to thirty tons of dead weight. Its effect on the rails was destructive, and it accounted for the necessity of frequent renewals. Mr. Fairlie illustrated by diagrams the mode in which a constant battering was kept up against the rails by the wheels under this arrangement, destructive alike to both; and how effectively this destruction was prevented by engines of his own construction—engines which would turn any curve and ascend any gradient; and he quoted Captain Tyler's and Mr. Eborall's report of their adaptability to such lines as the Grand Trunk of Canada, as combining a minimum of wear and tear to themselves and the rails, with a maximum of adhesion to the rails, and of economy in working. Models were exhibited in demonstration of these conditions, and after some further references to the necessity for the construction of cheap railways in Ireland, Mr. Fairlie concluded.

The paper was followed by a good discussion, at the close of which the Marquis of Clanricarde, in a very able and humorous speech, proposed a vote of thanks to Mr. Fairlie. The Marquis expressed himself very much in favour of Mr. Fairlie's system, and considered it particularly applicable to Ireland, where a cheap and efficient system of railways was very much required.

AERONAUTICAL SOCIETY OF GREAT BRITAIN.

THE proposition to hold an exhibition in London, of objects of an aeronautical character, having met with encouragement, the council have determined to act upon the proposition, with the hope that the guarantee and prize fund will be materially increased. The objects hitherto announced for exhibition promise interesting features for the engineer and mechanic, and there will not be wanting experiments of a practical character, which can scarcely fail to interest the general public. The objects are classified as—1. Light engines and machinery. 2. Complete working aerial apparatus. 3. Models. 4. Working models. 5. Plans and illustrative drawings. 6. Separate articles connected with aeronautics, including objects of interest illustrative and commemorative of previous experiments. 7. Kites or other similar apparatus proposed to be used in cases of shipwreck, traction, or in the attainment of other useful ends. 8. Painting and drawing of cloud scenery and landscape as seen from a balloon. The exhibition will be opened on Thursday, the 25th of June, at the Crystal Palace. Arrangements have been made, by order of the Treasury, for facilitating the passing of goods intended for the aeronautical exhibition, through the Custom House, upon the production of a document specifying the mark, number, and contents of each package. The packages will be received at the Crystal Palace on and after the 1st of June, until the day of opening. It may be observed there is no duty upon philosophical instruments or machinery of any kind.

The fund out of which prizes will be apportioned has not attained that amount which will allow of complete specification; but the council are gratified in being able to state that the Shipwrecked Mariners' Society have devoted £50 as a prize for the best form of kite or other aerial arrangement, or modification thereof, for establishing a communication from a wreck on shore, or between two vessels at sea. The Crystal Palace Company have also declared their intention of giving a prize of £50 to the exhibitor of a machine to carry and be worked by a steam engine or other motive power, which shall sustain and move itself in the air, at a height of not less than 10ft. from the ground, for a period of not less than twenty minutes. The Duke of Sutherland offers a prize of £100 to the inventor of a machine which, not being of the nature of a kite or balloon, shall ascend with a man to the height of 120ft. The Aeronautical Society offers a prize of £50, aided by the contributions of several members, to the exhibitor of the lightest engine in proportion to its power, from whatever source the power may be derived.

During the exhibition, it is proposed that daily experiments and partial ascents be made in a captive balloon, upon the plan lately pursued in Paris by M. Giffard. This gentleman's meteorological experiments, confined to an altitude of 1,000ft., were greatly appreciated by the higher classes, who crowded to take advantage of the opportunity to ascend to that height. Of the repetition now contemplated, Mr. Glaisher will probably largely avail himself. During the nine days that the exhibition will remain open under the auspices of the society, arrangements will be made for evening meetings of members and their friends, for explanation and discussion relative to the merits of the various objects exhibited.

MR. SEELY'S PIGS ONCE MORE.

IN our Parliamentary Notes last week, we stated our belief that Mr. Seely's pigs were a drug in the market, seeing that they still remained in dock. But it appears that we were mistaken, for instead of being a drug on market, they are so tightly tied down by red tape of the strongest make, that they cannot get loose from the dockyard. At any rate, this is the only conclusion at which we can arrive, after perusing a letter from Messrs. Shaw and Thompson, of Leadenhall-street, to Messrs. Bird, the metal merchants, of Laurence Pountney-hill. Messrs. Shaw state that on March 22, 1867, they bought, through Messrs. Wm. Bird and Co., 2,000 tons of "Seeley's pigs." They had the option, in the first instance, of taking 100 tons for experimental purposes, and were anxious to obtain immediate delivery of that quantity. They waited patiently, but in vain, for three months, to get delivery, and, at the end of that time, said to Messrs. Bird that if the Admiralty could be persuaded to give them only ten tons they would be willing to make a commencement. They could not even get ten tons, and state that the difficulty entirely lay with the Admiralty. It was only in December of last year, nearly nine months after their purchase, that Messrs. Bird were enabled to offer delivery of 100 tons, but in doing so they stated their inability to supply a further quantity. The natural consequence was that Messrs. Shaw abandoned the affair in complete disgust. They, however, express a very strong opinion that if this ballast iron were fairly tested, the 170,000 would soon be bought up.

GREAT NORTHERN EXPRESS ENGINE.

IN our page engraving we give a side elevation and sectional plan of one of the engines recently supplied to the Great Northern Railway Company by Messrs. J. Fowler and Co., Leeds, which are specially designed for running the heavy express trains on that line of railway. These engines have recently completed the journey from King's-cross to Peterborough, a distance of seventy-seven miles, in one hour and twenty-eight minutes, although they had to contend with heavy gradients for forty miles of the distance, and with twenty carriages behind them. The leading dimensions of these engines are as follows, viz.:—The driving and trailing wheels are 7ft. in diameter, and coupled together; the leading and tender wheels are 4ft. 3in. in diameter throughout; the barrel of the boiler is 10ft. 1in. long by 3ft. 10in. in diameter inside at the smallest part; the firebox casing is 6ft. 4in. long by 4ft. wide outside; the cylinders are 17in. in diameter, with a stroke of 24in.; the heating surface in box is 114¼ square feet, and in the tubes 907 square feet, making a total heating surface of 1,021¼ square feet, with a grate surface of 19⅔ square feet; the tender holds 2,500 gallons of water and two tons of fuel; the propelling power of the engine is equal to 12,000lb., and the adhesion on the rails may be taken at 11,700lb. The designs are by Mr. Sturrock, the late locomotive engineer of the Great Northern Railway, and the engines were built at Messrs. John Fowler and Co.'s works at Leeds, by Mr. Frederick Parker, the late manager of the works of the Great Northern Company at Doncaster, who has the entire management of their works. The engines are fine specimens of English workmanship and finish.

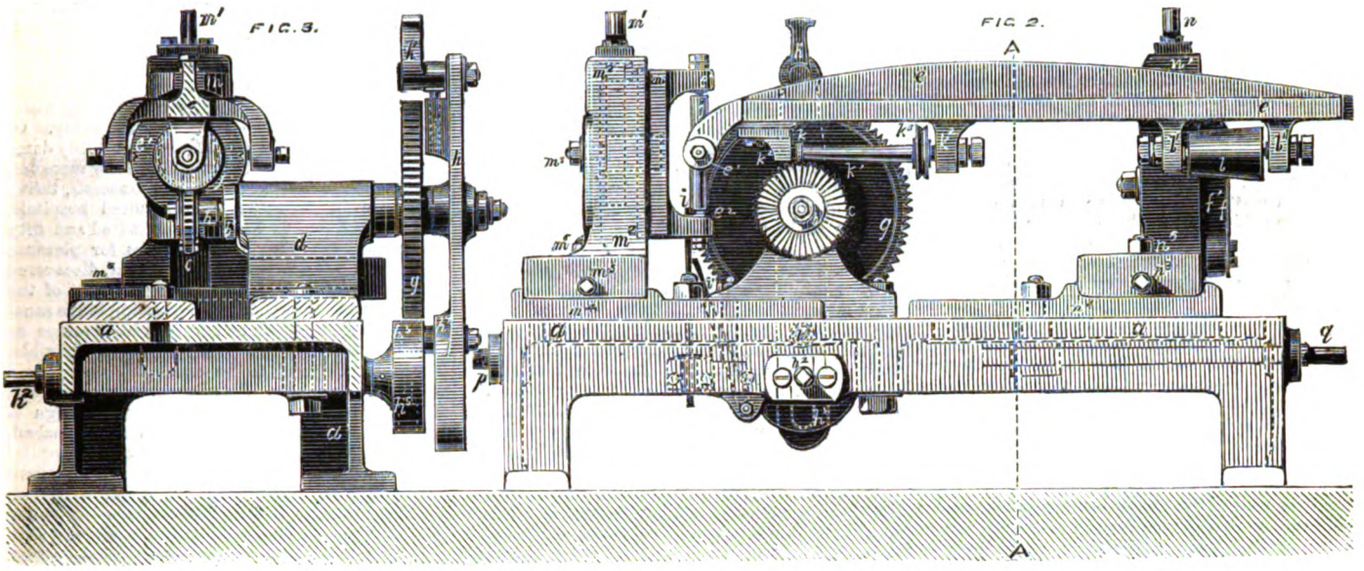
MACHINE FOR MANUFACTURING CIRCULAR CUTTERS AND MILLING TOOLS.

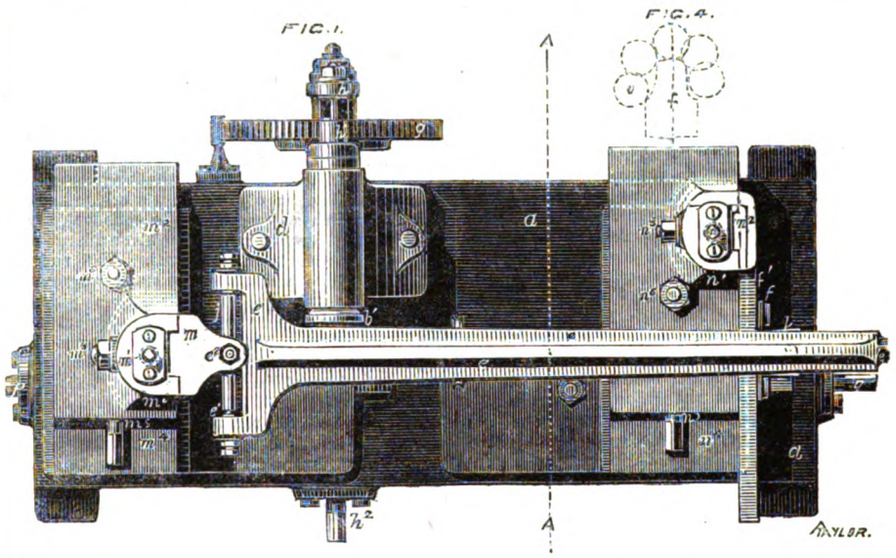
BY M. PAUL FRANCHAT.



MACHINE FOR MANUFACTURING CIRCULAR CUTTERS AND MILLING TOOLS.

THE above engraving illustrates some material improvements in machines for manufacturing circular cutters and milling tools, which form the subject of a patent recently granted in England to M. Paul F. Franchat, of No. 6, Passage des Jardins, Paris. Fig. 1 is a plan of the machine complete, fig. 2 a front elevation, fig. 3 a lateral sectional elevation through A A, figs. 1 and 2, and fig. 4, a diagram. This machine is composed of a table or frame a on which are fitted its four main or constituent parts, which are, firstly, a small horizontal spindle b carrying the cutter to be operated on fitted transversely over the table in a fixed support d. Secondly, a horizontal lever e suspended over the cutter at one of its extremities by an universal joint, and resting by its other extremity on an adjustable guide plate f; this lever carries the working cutter. Thirdly, a front adjustable headstock carrying the universal joint; and, fourthly, a back headstock, also adjustable, to which is attached the guide plate f on which the extremity of the lever e rests. The spindle b carrying the cutter is fitted into a little hollow shaft b^1 which is rotated intermittently in the standard d; a ratchet wheel g is keyed on the extremity of b_1, and outside the ratchet is hung a loose vertical lever h, to which is imparted a to-and-fro motion, in order to partially turn the ratchet either in one or the other direction, according to whether the pawl h^1 is turned over to the right or to the left. The to-and-fro motion is transmitted to the lever by making one revolution of the shaft h^2, which carries on its extremity a disc h^3 with a pin h^4 passing in a slot formed at the lower extremity of the lever h; this pin h_4, as shown in dotted lines, fig. 3, is attached to a small screw h_5, by which it can be moved from or brought towards the centre of the shaft h_2, in order to regulate exactly the throw of the lever, and, consequently, the number of teeth taken.

That the cutter may remain stationary whilst the cut is being made there is a spring lock i which penetrates one of the ratchet teeth, and before rotating the ratchet the spring is disengaged by the point of the lever i^1 suspended at i^2. To produce this result there is on the side of the lever a small roller i_3, and a nick is made on the circumference of the disc in which the roller enters whilst these parts are abreast, but immediately the disc commences to rotate, this roller is expelled from the nick, and the spring i disengaged, the roller remaining in contact with the circumference of the disc until an entire revolution has been completed. The horizontal lever e is suspended at one of its extremities by the two points e^1 e^1 which enter the disc j, so that without in any way moving this disc the lever can be raised and lowered, and since the disc is suspended on the two vertical centres e^2 e^2, the lever can also be moved in a horizontal direction, and by the combination of these two motions, any point within the range of the lever can be reached. The working cutter k is fitted underneath the lever e on a spindle k^1 revolving in bearings k^2 k^2; it is provided with a driving pulley ^{3} to receive rotary motion, and underneath the other extremity of this lever is a conical roller l turning freely on the points l^1 l^1, and



which, during the cutting, rests constantly on the guide plate f. The taper of this roller should correspond exactly with two lines converging to the centre of the disc j, its axis of rotation being exactly on a line with the centre.

According to the dimensions of the cutter to be cut, it is necessary that the position of the two headstocks may be varied vertically as well as transversely. For this purpose, with respect to the front headstock, the points e^2 e^2 of the disc are fitted in a vertical slide m which can be raised or lowered in the standard m^2 by the screw m^1, so as to bring the working cutter k on the top of the circumference of the cutter to be cut, whatever its diameter may be. The bolt m^3 serves to fix the slide at the requisite height, according to the depth or thickness of the cutter to be cut. The lever should be moved transversely, because it is advantageous that the working cutter should describe the same angle in order to reach one or the other of its extremities; for this purpose the standard m^2 is moved on the saddle m^4 by means of the horizontal screw m^5, parts being fixed in their requisite position with the bolt m_6. The same arrangement is adapted to the back headstock, its vertical motion being effected by the screw n in the standard n^1 moving the slide n^2, whilst the screw n^3 actuates the standard n^1 transversely on the saddle n^4; the bolts n^5 and n^6 serve to hold these parts in their definite positions.

In working the machine, the cutter to be cut c being fitted on its spindle b, the guide plate f is attached on the back headstock, which plate represents exactly, on an enlarged scale, the profile of the cutter to be cut (in practice it is found that the relation of five to one gives excellent results), care being taken that this plate coincides exactly in a line with the cutter. The workman then regulates the position of the lever e, so that the working cutter is brought exactly over the centre of the cutter c, whilst the conical roller l is over the guide plate f. He then adjusts the position of the pin h^4 in the slot of the vertical lever h, according to the number of cuts to be made on the cutter. Making sure that the little roller i^3 rests in the nick of the disc h_3, he holds the lever e raised by its handle e_4, puts the working cutter k in motion, and lowers laterally the lever e until its roller l bears on the extremity of the guide f, as shown at o, fig. 4. Then, pressing on the lever he passes the roller successively on the entire profile of the plate, thus making one cut on the cutter. He again raises the lever, bringing it to its former position, revolving once the shaft h^2, in order to rotate the cutter c the required quantity, and then makes another cut, repeating these motions until the entire circumference has been cut.

Instead of converging all the cuts to the centre of the cutter, it is sometimes advantageous that they take an angular direction; for this purpose M. Franchat has provided a means of bringing the working cutter out of the centre of the cutter being cut by moving the saddle m^4 with the screw p. In order to maintain the same relation of five to one between the cutter and the guide plate he also actuates the saddle n^4 by means of the screw q. This faculty of bringing the guide plate f closer to or further from the cutter by means of the screw q is also of great utility, inasmuch as by varying the fixed relation of five to one, it is possible to augment or to diminish within a perceptible limit the calibre of the cutters to be cut.

A RECENT circular from the Minister of Marine draws attention to the regulation which forbids all persons belonging to the French navy to wear moustaches or imperial, and only permits whiskers.

SOCIETY OF ENGINEERS.

AT the meeting of the Society of Engineers, held on Monday evening, March 16, Mr. Baldwin Latham, president, in the chair, the following paper was read on engineering in India, by Mr. F. C. Danvers, of the India Office:—

Abundant evidences exist that for many centuries past the natives of India have, from time to time, done much towards the improvement of their country by the construction of public works; for the remains of many such works exist to the present day, whilst others have been absorbed in the structures erected within the present century by our own engineers. A full account of the public works constructed by the earlier native rulers of different parts of India would suffice to fill a volume, and in the present necessarily hasty review of what has been done in that direction, it will be sufficient merely to refer to some of the principal noteworthy points of interest as proofs of the existence of a liberal and public spirit in former ages, such as can scarcely be said to be exceeded, if indeed it be equalled, by the present Government of Hindustan. It is worthy of remark that the principal evidences of civilization under former dynasties consist in the lasting monuments raised under their respective sways of public buildings, works for the supply of water, and the planting of trees along canal banks, and by the sides of so-called roads. The almost total absence of the use of wheeled conveyances, except by the wealthy of the land, caused but little attention to be paid to the proper construction of roads; and in many parts of the country even the use of water carriage, where available, would seem to have been but slightly employed.

It is unnecessary to refer more particularly to the numerous mosques and other public edifices which are to be found all over India, as evidences of the architectural taste of former ages, since pictures of many of them must already be familiar to all. With regard to the state of the country as to internal means of communication, the following is an extract from the "first report of the commissioners appointed to inquire into and report upon the system of superintending and executing public works in the Madras Presidency," dated December 23, 1852. In their review of the condition and the treatment of the roads in former times, the commissioners stated, "With regard to the communications of the country, the case was far otherwise" (than with works of irrigation). "It cannot be said that there was any capital invested in the ancient rods; and canals, for the purpose of navigation, had no existence in the south of India. Throughout the whole peninsula there was not one complete road of any length on which it would have answered to employ wheel carriages; their use, therefore, was very limited, and the distant traffic of the country had nowhere the advantage of them. Trucks were used by those who collected stone for the dams and tank embankmeuts, and in some localities the harvest was brought in by carts upon wheels, either formed of solid pieces of timber, or cut from a solid block of stone; these carts were drawn by several pairs of bullocks, and carried nearly a ton, but they were never used for distant journeys; even the main streets of many of the largest towns were not practicable for wheels; and when the most wealthy used light carriages, they rarely left the precincts of their village. The only made roads (if they deserve the name) were the mountain passes, which in the later wars were opened for the passage of artillery; but they had generally been destroyed by the monsoon rains, before the country came into the possession of the East India Company. The only proof of attention to the great roads was to be seen in the fine avenues of trees, which in some districts measured several hundred miles in length; but as the roadways beneath them had never been properly formed or drained, and bridges had not been built, or care taken to keep the pathway practicable, they were roads no longer; but in most cases, from being worn down by former traffic, and washed by the rains of the monsoon, they had become the drain of all the country that they passed through, and were so much more rugged than the land on either side, that their only use was as a guide to travellers who took a course as nearly parallel as the ground permitted. With such a want of roads, it might have been expected that water-carriage, wherever it was available, would have been turned to the best account; but such was not the case; little use was made of the rivers, and nothing seems ever to have been done to improve their navigation. In the heavy freshes, rafts of timber, and circular boats of wickerwork, covered with leather, were floated down some of the larger streams; but on very few of the rivers was any attempt ever made to take laden vessels up the stream. Still less use was made of the canals of irrigation, though many of them were well adapted for water-carriage during six or eight months of the year. The backwaters, both on the eastern and western coast, were turned to somewhat more account; but the boats in use upon them were canoes made from single trees, which, from their narrowness, and consequent deep draught of water, were very ill-suited to the shallow lakes they navigated. A considerable traffic was carried on by means of coasting craft, but that was expensive, slow, and dangerous. On the Coromandel coast the dhoneys were badly shaped for sailing, even when the wind was fair, and from their want of keel could never work to windward. In some respects the pattimar on the other side of the peninsula had advantages, being well built for speed, and having a better form of sail; but in both cases they were quite unfit to trust in such storms as the coasts are subject to. That the carriage was expensive to what it might have been, is to be accounted for by the indolent manner in which the vessels were worked, by the number of men necessary to manage their unwieldly sails, and the time lost by the necessity for waiting till the wind was fair. The cost was also greatly increased by the difficulty of shipping and landing goods, to facilitate which no attempt seems ever to have been made by any of the native rulers of the country."

Whilst on the subject of communications, it may be as well to notice a peculiar instance of a bridge constructed in Mysore, for facilitating access to the town and fort of Seringapatam, which is noticed by Dr. Buchanan in his account of a tour through that province at the beginning of the present century. "Seringapatam," he states, "as is well known, is situated at the upper end of an island surrounded by the Cauvery, which is here a large and rapid river, with a very extensive channel filled with rocks and fragments of granite. At certain seasons it is in many places fordable with facility; but during the rains it rises very high, to the great inconvenience of the inhabitants. On the south branch of the river a bridge has been erected, which serves also as an aqueduct, to convey from the upper part of the river a large canal of water into the town and island. The rudeness of this bridge will show the small progress that the arts have made in Mysore. Square pillars of granite are cut from the rock of a sufficient height to rise above the water at the highest floods. These are placed upright, in rows as long as the intended width of the bridge, and distant about 10ft. from each other. They are secured at the bottom by being let into the solid rock, and, their tops being cut to the level, a long stone is laid upon each row. Above these transverse stones others are placed contiguous to each other, and stretching from row to row in the direction of the length of the bridge. The whole breadth of this may be 20ft. One half is occupied by the aqueduct, which is secured at the bottom and on both sides by brick and plaster. The road is laid with gravel, and secured by a parapet wall on one side, and by the aqueduct on the other."

In Bengal, communications were almost entirely effected by means of the several branches of the Ganges River, which itself acted as the great highway between the Lower and North-Western Provinces for many years after the British occupation of Hindustan; and at the beginning of the present century the traffic on that river gave employment to no less than 20,000 boatmen. Many other rivers also were navigated to a limited extent in former days, including the Indus, the Godavery, and, indeed, most of the great inland rivers; but, under native rule, no attempts appear ever to have been made to improve their channels.

Some of the ancient Indian writings show how highly prized water has ever been for drinking and agricultural purposes, and that the natives used to consider the construction of such works not only an act of benevolence, but also one of religious merit. The Poorana, or ancient chronicles of India—which are Sanscrit works of considerable antiquity, the dates of their compilation being lost—give many proofs of this, as will be seen from the following extracts. In one place it is stated, "No satisfaction is felt without water in the three worlds—heaven, earth, and hell; therefore, a wise and learned man should cause reservoirs, tanks, wells, &c., to be made." Again, "A person that makes wells, gardens, establishments for the distribution of water—also, he that causes trees to be planted, gives his daughters in marriage to others, causes bridges, dams, &c., to be made over rivers—and all these for charity's sake—obtains a perpetual bliss in Paradise. Also a person in whose pond or lake there is a constant supply of water obtains perpetual felicity without question." And in another place it says: "Oh, thou son of Kunti, get large supplies of water made at the sacrifice of your whole property; for the man at whose reservoir the cow becomes satiated of her thirst, becomes the preserver of his family."

It is not, then, surprising to find that hydraulic works were early cultivated throughout Hindustan. The first Indian canal of which we have any satisfactory record dates from the year 1351, and it is stated to have been constructed by Feroze Toghlak, whose reign was distinguished by many improvements in legislative and fiscal policy. Of this monarch it is recorded that he built fifty dams across rivers to promote irrigation, forty mosques, thirty colleges, one hundred caravanserais, thirty reservoirs for irrigation, one hundred hospitals, one hundred public baths, one hundred and fifty bridges, besides many other edifices for pleasure or ornament. An interesting document, discovered by Lieutenant S. A. Abbott, being a decree of the great Akbar, dated A.D. 1568, referring to the canal of Feroze Shah, which at that date had become so choked that its bed was scarcely discernible, directed the canal to be excavated deeper and wider than formerly. Sixty or seventy years later, new works were undertaken during the reign of Shah Jehan. The foundation of Shahjehanabad, and the natural desire to secure for his new capital and favourite residence the benefit of an abundant supply of water, induced the Emperor to project the Delhi Canal. In Ali Murdam Khan—a person distinguished for his architectural taste and skill—he found an agent admirably qualified to give effect to his wishes. For a century and a quarter after its original construction, in 1626, the Delhi Canal continued efficient. Aged men informed a British officer, on survey duty in the neighbourhood in 1807, that they were finally deprived of the canal water about the year 1753, in the reign of Alumgir II. The canal of Feroze had ceased to flow in Hurriana about 1707, and at Suffidun in 1740; so that the Mogul canals became practically extinct nearly in the middle of the eighteenth century. About the year 1780, Zabita Khan, Rohilla, is said to have reopened the Eastern Jumna Canal—a work which is also attributed to Ali Murdan Khan—but his canal is supposed to have remained open only for a few months. The late Colonel Baird Smith, from whose writings the above information regarding early irrigation works in India has been obtained, remarks that the canals of the Mahomedan dynasty in the North-Western Provinces of India were remarkable for their sinuosity of channel, arising from an ignorance of the modern means of regulating the excessive slope of the country, and an irregularity in the distribution of the fall, which caused alternations of rapids with almost still water.

Irrigation works seem to have been very general in the Peninsula of India under its native rulers; but in this part of India tank irrigation was perhaps more general than canal irrigation, although there were evidently many works also constructed of the latter class. Some very interesting works in the Southern Maratha country are clearly traceable to the Hindoo dynasty, and those about the headwaters of the Tombuddra and its tributaries may be especially referred to. "In the delta lands of Tanjore," says Colonel Baird Smith, "it is probable that artificial irrigation was contemporaneous with agriculture itself; but the first marked development of that native system upon which modern improvements have been grafted is traceable to a period corresponding with the close of the second century of our own era, and to the reign of a certain Rajah Veeranum, to whom many of the gigantic pagodas, as well as the great irrigation channels in Tanjore, are attributed. It is worthy of remark that these works were all executed under an intrusive and foreign monarch, who, leading an army from the comparatively desolate tracts in the northern portion of the Peninsula, established himself in the fertile southern regions. In the Teligoo country, from which the invader came, there is not a trace of any such contemporaneous works as are found in Tanjore; and it gives a striking idea of Rajah Veeranum's clearness of perception and energy of character that he should at once have appreciated the system of irrigation pursued by the subject race, and should have given to it that vast and rapid development which, making allowances for exaggeration, is still distinctly traceable to his reign. In the religious works of the period there are evidences of great constructive skill, immense labour, and, in some respects, marked architectural

Digitized by Google

taste; while in the works of irrigation there is great boldness of design, considerable knowledge of hydraulic principles, mixed, however, occasionally with curious indications of ignorance, a massiveness of construction so disproportioned to the necessities of the case, as to indicate a very exaggerated idea of the forces dealt with. There was, however, one great object which was entirely lost sight of, and this was the means of intercommunication; for, while the soil was fertilized and protected, its produce found its way into commerce through all sorts of difficulties, from the entire absence of roads, bridges, and other elements of free movement. Besides canals, which were taken from the rivers of the district, tanks were largely employed for purposes of irrigation; and some of these were formed on such a scale as fairly to be denominated gigantic. The embankment of the Poonary Tank, in the Trichinopoly district, for example, was thirty miles in length, that of the Veeranum Tank about ten miles; and numerous others of scarcely inferior dimensions are scattered over the face of the country. All these tanks were provided with sluices for distributing the water to the fields, with escape weirs for regulating the surface level of the water, and with other necessary works of detail. The same authority also refers to native works of a similar character which were in existence in the delta of the Kistnah when the country fell into our hands in 1766. In Guntoor, two ancient channels, having all the characteristic marks of natural rivers, and called respectively the Boodaimair and Pollier, traverse the district in different directions, and for ages have been subservient to the irrigation of the Delta. All the irrigated portion of the Madras Presidency abounds in tanks, and the extent to which tank irrigation there is extended is truly extraordinary. An imperfect record of the number of tanks in fourteen districts shows them to amount to no less than 43,000 in repair and 10,000 out of repair, or 53,000 in all. It would be a moderate estimate of the length of embankment for each to fix it at half a mile; and the number of masonry works in sluices of irrigation, waste weirs, &c., would probably not be overrated at an average of six. These data, only assumed to give some definite idea of the extent of the system, would give close upon 30,000 miles of embankments (sufficient "to put a girdle round the globe" not less than 6ft. thick), and 300,000 separate masonry works; and the whole of this gigantic machinery of irrigation is of purely native origin.

Turning now from ancient to modern engineering works, it is purposed to give a brief account of some of the principal peculiarities of construction as adopted in India. The principal public buildings of modern date will be passed over as appertaining generally more to architecture than engineering.

With respect to communications, there are two classes of roads generally constructed in India, viz., what are called "fair-weather roads," and "first-class roads," the former of these being often little better than cleared tracks, whilst the latter are both bridged and metalled. Prior to the introduction of wheeled conveyances into the country, camels, horses, mules, asses, and bullocks, and not unfrequently even sheep, were employed for the purposes of transport. To construct a fair-weather road, the line is first cleared of jungle for a width of 10ft., 20ft., or 30ft., a ditch is cut on either side to serve as a drain, and the earth excavated is thrown into the centre of the road to assist the rain water to run into the ditches. It is necessary, of course, to level inequalities of surface as far as possible, and small streams are either crossed by means of temporary bridges, if wood is available, and, if not, their banks are cut down, if necessary, to a gentle slope, so as to enable carts to pass when the stream is dry, or nearly so, and such slopes, as well as the bottom of the stream, are in some instances paved, if material suitable for the purpose is available. There are several temporary expedients which may be used as a substitute for metalling; thus stable litter, when available, or even grass strewed on the sandy or dusty surface, will greatly improve it. A road passing through the deep sandy bed of a river may be much improved by cutting down through loose sand to the moist and firmer stratum; on this should be laid a flooring of fascines 6in. in diameter, made of jhow, or of the strong grass which generally grows upon the banks of rivers in that country, and over all, from 1ft. to 1ft. 6in. of earth well beaten down. This plan has been pursued with great success at several of the large rivers, such as the Sutlej. Such a road will hardly last more than one season, but it is inexpensive and greatly facilitates the draught of heavy loads.

Of first-class roads it is not necessary to say anything here beyond that they are rendered passable for wheeled conveyances during the whole year, being metalled and bridged, whereas the fair-weather roads just referred to are generally only passable for, at most, nine months in the year. Even in first-class roads the metalling does not always extend across the entire width of the roadway, but it is often confined to the central portion of it.

For the purposes of crossing rivers there are several temporary expedients which are often resorted to where the want of time, money, or skill prevents the employment of more durable methods. Many Indian watercourses are dry, or nearly so, except during the rainy season, and in some of the very dry districts of the North-West, the watercourses often contain no water for eleven months out of the twelve. The beds of such rivers or streams are, therefore, in general, passable without a bridge, but they require to have the banks cut down to an easy slope, and the bed of the stream to be paved for a sufficient width to save the labour of draught through heavy sand, or sand and water combined. The largest of such causeways is that constructed across the bed of the River Soane on the line of the Grand Trunk road. The distance from the western extremity, or head of the causeway, to the point where the Baroon bank of the river rises above ordinary floods, and the metalled Grand Trunk road again commences, is 11,450ft. The line of the causeway having been marked out, common jungle piles were driven in two parallel lines, at a distance of 17ft. apart, to a depth of about 15ft., the sand having been excavated with shovels in the ordinary way. Between these piles down to the water-level, or a little below, bamboo frames with palm-tree leaf mats were forced down behind, to prevent the sand from the sides slipping into the excavation. The remainder of the sand below water-level was excavated to the required depth by means of the ordinary well sinkers' jham, worked from temporary stages on either side of the excavation. A layer of gunny bags filled with concrete composed of two parts Soane shingle, one part soorkhee, and one part kunkur lime, was then set as closely packed as possible over the whole bottom of the excavation. Over this a layer 2ft. 6in. deep of rubble stone was placed, set in concrete, of the same proportions as above, and on this the roadway, formed of roughly cut stone slabs 1ft. thick, from 1ft. to 1ft. 6in. broad, and alternately 9ft. and 7ft. long, so as to break joint with each other.

Temporary wooden bridges of the simplest type are sometimes used; and rope bridges are employed, of various designs, to cross mountain torrents which run between high steep banks on the hills. In some of the latter a single rope is stretched across the stream, and made fast to trees on either bank; a sort of cradle in which the passenger sits is slung on the rope, and pulled across by means of ropes worked from either shore. In others the bridge consists of three ropes, one for the feet, and two others for the hands of the traveller, kept asunder by triangular pieces of wood placed at intervals.

Ferry boats are in use on nearly all the large Indian rivers, but these are often replaced by boat bridges during the cold season. Boat bridges are maintained over all the great rivers on the main lines of road from September to June, and, occasionally, all the year round, where the stream is not too wide, or where it can be narrowed by the embanked road being carried forward on each side, so as to restrict the deep channel within reasonable limits.

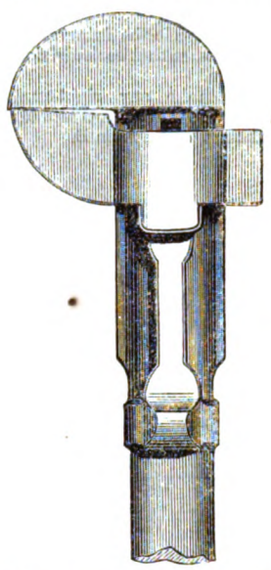
Permanent bridges are made of wood, brick, stone, and iron. The use of wooden bridges is, in India, generally confined to places in or near the hills, where wood is cheap and plentiful; they are also sometimes used in the plains as temporary structures, until it is convenient to construct them in a more permanent manner; but the destructibility of the material, and the liability of its parts to be deranged by the violent atmospheric changes common in the East, render its employment in general unadvisable.

(To be continued.)

"BARNUM'S Museum" in New York was completely destroyed by fire on the night of the 2nd inst., involving a loss of 500,000 dollars. This is the second time within a short period that the famous showman has had his museum burnt, the "New York Herald" building being erected now on the site of the former museum.

WESTON'S PATENT SPANNER.

ONE of the most original and ingenious inventions we have seen for some time is illustrated in the accompanying engraving. It is a spanner which has been invented by Mr. W. T. Weston, and is now being manufactured in large quantities by Messrs. Timmins and Son, of Birmingham. In principle this spanner somewhat resembles Mr. Weston's cramp, in which the lower jaw slides freely on a flat bar of peculiar form. The slightest pressure at the extremity causes it to grip the stem, so that it remains firmly fixed. In effect this movable jaw is a lever of the first order, and any pressure applied at its extremity forces the sliding part into a slightly oblique position when it jams the stem. The jaws of a spanner being shorter than those of a cramp necessitated a further development of the prin-



ciple, which has been satisfactorily effected by Mr. Weston. The result is a spanner without screw or ratchet, and which can be instantly adjusted to fit any nut or bolt. The movable part consists of the hinder jaw of the spanner, which is provided with studs connected by two side straps, with a sliding band, by which means the jaws are kept parallel and to place them under the control of the thumb. The lower jaw is slid up to the required position upon the nut, and there remains fixed so long as the pressure of the work is kept upon it. On being released from the nut the jaw slides down to a stop on the handle. A trial of this spanner convinces us that it is a most useful tool, having the advantage of fitting any sized nut, and being of general utility in the engine room or workshop.

IMPROVED METHOD OF DIVIDING THERMOMETERS.*

By MR. WILLIAM ACKLAND.

IN the manufacture of thermometers for low temperatures, considerable difficulties are experienced, owing to equal increments of temperature not causing an equal increase of volume of the fluid employed; and this unequal expansion gives rise to considerable errors, even within limited ranges of temperature. If, in constructing an alcohol thermometer, we select a tube with uniform bore, we find, on giving it certain fixed points, corresponding to an equal number of degrees between each point, that the spaces so obtained are each diminishing in length as we descend; hence the ordinary mode of equal divisions between the ascertained points is found to give inaccurate results. An important question therefore arises—Can we so subdivide our tube that each subdivision shall be in its proper place?

During the autumn of last year, Mr. Glaisher mentioned this subject to me, and at the same time offered some valuable suggestions to remove this difficulty, and caused me to direct my attention to this subject. Many subsequent interviews with that gentleman, extending over some months, enabled me to mature my first idea, and aided by his valuable assistance and counsel, the success aimed at has been attained; and I am now in a position to state that I have completed a dividing-engine on an entirely new principle, which may

* Proceedings of the Meteorological Society.

Digitized by Google

strictly be termed "Interpolating;" for, whilst between any consecutive terms taken at regular and fixed intervals we can, by numerical interpolation, find intermediate terms conformable to the law of the series; so, between fixed and determined points of our thermometer, we can, by using the "interpolating-engine," so divide the intervening spaces that they shall conform to the varying nature of the series, or, in other words, that the divisions shall increase in magnitude as we ascend the scale in such proportions as are demanded by the expansion of the alcohol and the bore of the tube employed.

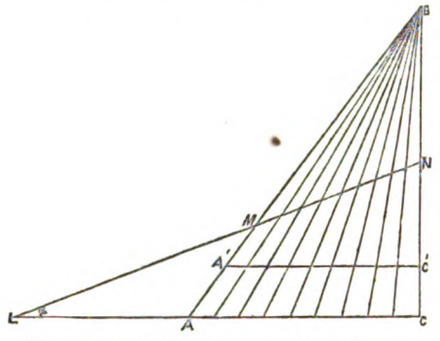
To illustrate this new method I have invented, let us suppose we have obtained the fixed points, P Q R S, of a thermometer corresponding to equal differences of temperature. And let

$$P Q = x_1,\ Q R = x_2,\ R S = x_3$$

	x_1	x_2	x_3	
P		Q	R	S

It is desired to divide the intervening spaces each into ten divisions, so that each division shall occupy its true position.

To do this, take any right-angled triangle, A B C, and divide the side A C into ten equal parts by straight lines drawn from B.



Then, if a straight line, as A' C', be drawn parallel to A C, it will be divided into ten equal parts: but if it be drawn not parallel to A C, it will be divided into ten unequal parts.

To apply this to the thermometer to be divided, draw a transversal L M N cutting A C produced in L, at an angle ϕ, so that

$$\tan.\ \phi = \frac{x_2 - x_1}{x_2 + x_1} \tan A,$$

and

$$M N = x_1.$$

On doing this it becomes evident that such a line, so placed, will be divided into ten unequal parts, proportionate to the law governing the series, and we can in the same manner, by using the same formula, divide any number of spaces with equal accuracy. It remains, therefore, mechanically to transfer such divisions to our thermometer, previously marked off at equal intervals of temperature, in order to secure its correctness to even second differences. This mechanical copying can be done by the dividing-engine before referred to; and it is worthy of note that the formula and engine equally apply to the more correct dividing of mercurial thermometers having unequal or varying diameters of bore, as also to the construction of hydrometers of absolute accuracy.

I can easily understand that whilst the mathematician may appreciate the formula thus introduced, and also its successful application, those accustomed to the construction of thermometers would hesitate to adopt it, from the fact that the plan involves a series of calculations for each thermometer, which would involve considerable loss of time and risks of inaccuracies, if these computations were hastily done; hence my first idea was to compute a series of tables; but this was attended with only partial success. My attention was then directed to the mechanical solution of these problems, the result of which was the invention of a little piece of apparatus, which may be called a computer, consisting of a sliding-rule, index-arm, and scale. Suppose we wish to divide accurately the space x_1, formerly given; we set the distance from P to Q on the slide, to that of Q to R on the fixed scale, and the index-arm at once points to the angle on the scale which M N must make with A C on our divided triangle. In use, this computer is found both trustworthy and simple, and facilitates what would otherwise have been tedious to perform and liable to inaccuracies when done.

Having devised a method of dividing a thermometer tube accurately, I next turned my attention to the most suitable strength of alcohol to be employed in filling these thermometers; and as but little can be gained by referring to our scientific writers on this subject, I undertook a series of experiments to satisfy myself on this point. Now it is well known that the expansion of alcohol by heat is not proportionate to its change of temperature; and we are consequently unable to express its corresponding coefficient by a simple formula, as for metals and mercury, but must adopt the more complex expression of M. Biot,

$$d = a\ t + b\ t^2,$$

where a and b are the required coefficients, and t the temperature. The coefficients of absolute alcohol are constant for all temperatures, but inasmuch as this fluid becomes weaker from momentous exposure to the air, and the mere pouring from one bottle to another not only alters its specific gravity but also its rate of expansion and its coefficient, it becomes an important point to select some other strength less liable to those changes, which only tend to inaccuracies, however much we may strive to prevent them. In making this selection, various specific gravities and of varying purities were tested, and the results led to the selection of alcohol having a specific gravity of ·815, as spirit of this strength, if pure, and free from methylated spirit, fusel-oil, &c., has its coefficients as constant as those of absolute alcohol, and it is but little liable to undergo those changes that seem to thwart our efforts when using a stronger sample.

I had entertained a hope that at this meeting I should have been enabled to have exhibited a series of alcohol thermometers made on the principle above indicated; but a few only have as yet been completed. Those accustomed to scientific investigations will readily appreciate the difficulties met with at every stage, and I must plead the little time at my disposal for the present deficiency, and merely state in conclusion that, before any lengthened period, thermometers made on the plan above indicated, will be ready for those who may wish to tsst their accuracy.

THE NEW DUTCH ARMOUR-CLAD RAM

ON Tuesday last, Messrs. R. Napier and Sons launched from their shipbuilding yard at Govan, near Glasgow, an armour-clad twin-screw turret ram named the "De Buffel," designed and built for the Dutch Government. This new war ship is of about 1,473 tons, builders' measurement. She is 205ft. in length by 40ft. beam, and 24ft. deep. Her sides are plated with armour 6in. thick, backed with 10in. of teak on an inner skin, right forward and aft, extending 3ft. below, and 2ft. above the water-line, and thus protecting the most vulnerable part of the vessel. The main deck consists of 6in. of teak on a 1-inch plate. The wall on the main deck round the base of the turret, which is constructed on Captain Coles's principle, is composed of "eight armour backed by twelve" teak on an inch inner skin. The armour and backing on the turret are similar to those on the wall. The "De Buffel" is to carry two 300-pounder 12½-ton Armstrong guns in the turret, and four smaller broadside guns on the main deck. Her guns train right round the circle, with the exception of a few degrees on each side the keel aft, the funnel preventing the circle from being completed. The turret may be worked by steam, under the care of one man. Accommodation is provided on the main deck for the officers and crew, whose comfort has been considered in every respect in the construction of the vessel. It is expected that the "De Buffel" will attain to a speed of about 13½ knots per hour. Her engines, also constructed by the Messrs. Napier, are of 400 nominal horse power, fitted with surface condensers, superheaters, &c. The "De Buffel" is the second ironclad for the Dutch Government which has issued from the works of Messrs. Napier within the last three weeks, the "D Tijger," a monitor, having been launched within that period.

THE ROYAL MICROSCOPICAL SOCIETY.

AT the ordinary meeting, held at King's College, on Wednesday, the Rev. J. B. Reade, F.R.S., vice-president, in the chair, five new fellows were elected. A paper was read by Dr. Muirhead on the "Classification and arrangement of objects in microscopic cabinets," in which, after reviewing the various methods which had been from time to time adopted, preference was given to the plan of Professor Quekett, with some slight modifications. A paper was also read by Dr. Collingwood "On the Algæ which cause the coloration of the sea in various parts of the world." This was for the most part a detail of the results of personal observation and examination in the India and China seas, where the author had frequently found the water to be deeply tinged of a yellow or brown colour by immense quantities of microscopic algæ, chiefly being species of trichodesmium; but neither he nor any of the speakers who took part in the discussion had ever observed the sea to be coloured red as so often described by early writers upon the subject. A binocular microscope with a new rotating glass stage was exhibited by Messrs. Crouch; and Mr. C. Collins introduced a new metallic chimney for microscope lamps, which appeared to be admirably adapted to the purpose. The presents to the society since the previous meeting included a series of slides and models, from the Rev. Lord S. G. Osborne; a very valuable and complete series of preparations of bones and teeth, numbering 434 slides, from Mr. Joseph Beck; and a first-class binocular microscope, from Mr. Baker.

OPENING OF THE MILLWALL DOCKS.

ON Saturday last the new docks at Millwall were formally opened with as much ceremony as could be imported into the occasion. These docks will prove of great benefit to the river, as it forms an important addition to its private dock accommodation. The docks and warehouses occupy about 204 acres, and of this extensive area there are 35 acres of water for dock accommodation. When the scheme is entirely completed, there will be upwards of 52 acres, leaving 152 acres available for wharves and warehouses. The floating dock is 350ft. in width; it has two entrance locks, one, the first, of 250ft. long, and the second 200ft., and both with a width of 80ft., and a depth at the sill of the lock of 28ft. below Trinity high-water mark. This allows for the admission of vessels of greater length and breadth than any at present built, the "Great Eastern" alone excepted. Near the floating dock is a graving dock for the repairs of vessels. Its length is, inside the sill, 415ft., and its width 65ft., with a depth of water of 25ft. below Trinity datum. All the locks are provided with hydraulic power for working the gates, the bridge, and sluices, and one 3-ton and one 5-ton capstan. Hydraulic power is also applied to the drawbridge between the inner and outer dock, and to some of the cranes in connection with the warehouses. Nine warehouses have already been constructed, two of which are 300ft. long, four 200ft. long, and three 100ft. long. They are fitted with twelve 35-cwt. cranes, one 5-ton crane, one of 15 tons, and a sheerlegs, equal to a weight of 80 tons, is in course of erection. The works have been constructed well and cheaply, the land not having been costly to acquire. The docks offer unusual facilities to vessels entering or leaving the river; there is ample railway communication close at hand, and, if a short canal of about 200ft. long were cut, it would give access to the West India, and through them to the East India Docks, thus opening up one of the finest series of docks in the kingdom.

THE ABERDEEN EXHIBITION OF 1869.

WE are glad to inform our readers that arrangements are now far advanced for the Arts and Manufactures Exhibition, which is intended to take place at Aberdeen next year. The exhibition will consist of two branches—one an art collection, including art manufactures; the other industrial, including materials and machinery as well as manufactures. It is intended that the whole collection exhibited shall be drawn from the northern counties of Scotland, except in respect to the works of native artists and the products of native workmen's skill or ingenuity, which will be sought for wherever they can be procured. The line of division, marking the northern counties of Scotland, may not be very strictly adhered to, but it is generally understood to be the River Tay. The exhibition will thus be strictly a representative provincial one, and whilst this plan in some respects limits the extent and importance of the collection, on the other hand it will attach to it a special interest. We believe, however, that the north of Scotland will not be found deficient in native talent, whether in art or mechanical skill. And some branches of industry, such as granite cutting and polishing, are almost peculiar to the district, whilst in others, such as shipbuilding, special excellence has been attained. The Queen has consented to patronize

Digitized by Google

the undertaking. The Prince of Wales allows himself to be named president, and the list of its supporters already includes nearly all the nobility and prominent men of all classes in the north of Scotland. It is contemplated that the exhibition will take place in the months of July, August, and September, 1869, being the time of the year during which the north of Scotland is thronged with strangers from the south, and when most of the proprietors are at home. At that season also, excursions might be expected to be made from populous places at a distance, partly attracted by such an object of interest.

Correspondence.

SQUARING THE CIRCLE.

TO THE EDITOR OF THE "MECHANICS MAGAZINE."

SIR,—The Observatory at Greenwich was built in 1665 for Flamsteed, who was the first astronomer paid by the British Government to discover the best method of finding the longitude at sea. On his first-class observations, Newton mainly calculated by his doctrine of infinite approximation his theory of the moon. But this method, even in his own hands, was so fallible that his computed place for the moon was frequently in error of the true place as much as 5min. of time=1¼deg. of longitude. In 1719 Halley succeeded Flamsteed at Greenwich, and during his life somewhat greater accuracy was obtained in computations from the theory of the moon. Dr. Maskelcyne became Greenwich astronomer in 1765, a position which he occupied for forty-seven years. Two years after his accession the first British "Nautical Almanack" was published under his auspices, the principal approximative accuracy from which was attributable to the theory of the moon and accompanying tables of Tobias Mayer, of Maspach, adopted by the Board of Longitude in 1770, and for the copyright of which a sum of £3,000 was paid to Mayer's widow. The amount of practical accuracy at this time in determining the longitudinal position of a ship at sea with the help of the "Nautical Almanack" is well described by Dr. Hutton, as follows:—"These new tables, when compared with the above-mentioned series of observations, a proper allowance being made for the unavoidable error of observation, seem to give always the moon's longitude in the heavens correctly within thirty seconds of a degree, which greatest error added to a possible error of one minute in taking the moon's distance from the sun, or a star at sea, will at a medium only produce an error of forty-two minutes of longitude." This, too, was after the invention of Harrison's chronometer, for which the Board of Longitude rewarded him with £24,000. Dr. Hutton adds, "It is well known that from various unavoidable causes all astronomical computations are but approximations to perfect accuracy." I shall leave this approximation at the point to which it had been brought last year by quoting the words of Edwin Dunkin, F.R.A.S., of the Greenwich Observatory, viz:—"The publication of the reductions of the Greenwich observations of the moon, made since 1750 up to a modern date, has to a great extent been the origin of all these important investigations. As one great result, Professor Hausen, of Gotha, using these observations for the perfection of the theory, has formed lunar tables, which from their general agreement with a considerable number of modern observations with which they have been compared, are considered worthy of being classed amongst the greatest triumphs of theoretical astronomy."

I do not wish by this statement of facts to underrate the "Nautical Almanack," but merely to confine it to its proper sphere of a comparatively useful theoretically approximative publication, but at the same time destitute in any sense of a geometrically exact result. I trust your correspondent, "Commander, R.N.," will reconsider his expression in his letter of 9th current, "and as the computed distances agree exactly with the observed distances, the accuracy of the value of trigonometrical lines may be safely accepted." If we "may reasonably rely upon the trigonometrical survey of England," how has the director of that survey—Colonel James—committed the error I pointed out in my letter of 19th December last. We might just as reasonably rely on the wondrous paralogism advertised in your columns, a week or two since, by "Edward Thornton on the Quadrature of the Circle."

In reply to Mr. T. C. Haines, 2nd March, I refer him to my question to Mr. W. Hayden in the same number of your Magazine. When I have their answer to that question I shall show them what they now ask for.—I am, Sir, yours, &c.,

London, March 14. WILLIAM HARVEY.

THE steam line between Baltimore and Liverpool is again in operation, after a suspension of several months. The steamer "Worcester" cleared for Baltimore on the 26th of February for Liverpool.

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith.—ED. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

RECEIVED.—J. M.—Messrs. C. G. and Co.—E. S.—G. W. H.—Messrs. A. M. and Son—J. L. N.—G. W.—G. G. P.—E. M.—W. L. Y.—W. H.—A. W.—G. L.—T. I.—T. W. T.—C. B.—S. K. M.—J. B. T.—F. W. B.—N. M.L.—R. F. F.—W. Meetings for the Week.

MON.—Royal Geographical Society.—"A Journey to Shasa and the Source of the Brahmaputra." By a Pundit, under the direction of Captain T. G. Montgomerie, R.E., at 8.30 p.m.

TUES.—The Institution of Civil Engineers.—Continued discussion upon Mr. Sandberg's paper on "The Manufacture and Wear of Rails," at 8 p.m.

Royal Institution.—Dr. Foster on "The Development of Animals," at 3 p.m.

WED.—Society of Arts.—Mr. A. S. Bicknell, on "Horse as an Article of Food," at 8 p.m.

THURS. — Royal Institution.—Dr. Foster on "The Development of Animals," at 3 p.m.

Aeronautical Society of Great Britain.—Reading and Discussing Papers, at 8 p.m.

FRI. — Royal Institution. — Dr. Carpenter on "The Unconscious Action of the Brain," at 8 p.m.

Royal United Service Institution.—Major S. Bevan Edwards, R.E., on "An Organization for the Army of England," at 3 p.m.

Society of Arts.—Chlorine and its Compounds with Oxygen. Chlorate of Potash—its Manufacture and Remarkable Properties. Hydrochloric Acid, or Spirit of Salt—its Production and Applications in Arts and Manufactures, viz., Galvanizing of Iron, Sal Ammoniac, Chloride of Tin, &c. Illustrations. At 8 p.m.

SAT.—Royal Institution.—Professor Roscoe on "The Non-Metallic Elements," at 3 p.m.

Naval, Military, and Gunnery Items.

IT appears from advices from Annesley Bay of the 19th of February that the vessels of the British India Steam Navigation Company had done good service, not only in landing troops and stores without accident, but also from the fact that by their powerful condensing apparatus they were able to supply daily to the troops many thousand gallons of good fresh water, not otherwise to be obtained.

The Bureau Veritas states that the number of vessels totally lost during the month of January was 264—viz., 141 English, 35 French, 24 American, 12 Prussian, 8 Dutch, 7 Norwegian, 5 Danish, and 32 of divers flags. The number of steamers included in the above enumeration was ten. There is a diminution of 157 vessels, as compared with the corresponding month of 1867, and 147 with that of 1866.

WE are glad to observe that notice has been given that rolls of officers and men of No. 6 company, 11th Battalion, Royal Artillery, who were employed in the operations leading to the capture of Banda and Kirwee, between the 19th of April and the 6th of June, 1858, has been received at the Secretary's office, Royal Hospital, Chelsea, from the Government of India, with authority for the payment of the shares of prize money, including first and second distributions, to which they are respectively entitled; and that such payment, in the proportion of £63 to each individual or private's share, will commence on the termination of one month from the 11th inst.

Two fine new lifeboats have just been sent by the National Lifeboat Institution to the coast. One of them is stationed at Ross Links, Holy Island, where Grace Darling immortalized her name by her heroic services to the crew of the "Forfarshire" steamer, which was wrecked off that place in 1838. The Ross Links boat, which is 32ft. long, is named the "Bombay," and is the gift to the institution of Mr. and Mrs. J. G. Frith, of London. The second boat has been sent to Stonehaven, on the east coast of Scotland, and is named the "St. George." This boat was presented to the society by Mrs. George Burgess, sister-in-law of Captain Burgess, secretary of the United Service Institution.

ONE of the eight gunboats now building in private yards for the Admiralty, was launched by Messrs. Pearse, Lockwood and Co., Stockton, on Tuesday week. She is named the "Hornet," and has been built from the designs of Mr. E. J. Reed. Her dimensions are—length between perpendiculars, 155ft.; breadth, moulded, 25ft.; depth, 14ft. 2in.; burden, in tons, 463 88-94. She is a composite vessel, having iron frames, beams, &c., covered with two thicknesses of teak planking, the whole of the fastenings being of brass and copper. She is bark rigged. Her armament will consist of two guns, one 100-pounder, and one 64-pounder. Her machinery consists of two pairs of horizontal trunk engines, with three boilers of the nominal power of 120 horses. She is on the twin-screw principle, one pair of engines driving each propeller, the latter being of gun-metal, and of the form known as Griffith's patent. The "Hornet" is for the Indian service, and, when fully equipped, will only draw 7ft. of water.

FROM the Clyde we learn that Messrs. A. and J. Inglis, of Point House, have launched an iron twin-screw, named the "Selix," for the South American trade. Her dimensions are 170ft. by 27ft. and 9ft. The vessel will be fitted by her builders with two pairs of compound engines of 90-horse power nominal collectively. Mr. J. G. Lawrie, of Whiteinch, has launched a screw of 1,000 tons, named the "Illawarra," intended for the conveyance of passengers in Australian waters. The "Bremen, screw, built by Messrs. Caird and Company for the North German Lloyd, has made an excellent run from the Clyde to Bremen; she will ply between Bremen and Baltimore, via Southampton. The screw steamer "Dunvegan Castle," recently launched by Messrs. Blackwood and Gordon, of Port Glasgow, and owned by Mr. Lang, of Groatholm, has made a trial trip. The steamer, which is intended for the Highland trade, attained during the trip an average speed of about thirteen miles per hour.

THE officers of the Royal Artillery have taken M'Lean's Gallery, No. 7, Haymarket, from the month of June next, for the purpose of exhibiting original pictures, photographs, and sketches, the work of members of the corps. Our readers are doubtless aware that drawing is taught to the cadets at the Royal Military Academy, and the universal service of the regiment affords artillery officers excellent opportunities for describing, by the pencil or the camera, scenes to which artists never penetrate. It is not probable that the exhibition will claim notice for the artistic value of the works. Indeed, the committee, in a circular lately issued to all stations, grounds its appeal to officers upon the unusual character of the works likely to be exhibited. There will be framed pictures and drawings upon the walls, but the chief interest of the exhibition will probably consist in the sketches from nature, which will be shown in portfolios. Any surplus funds remaining after the expenses have been defrayed, will be devoted to some charitable object connected with the corps, and the exhibitors confidently expect that the novelty of the scheme will attract a considerable number of visitors.

THERE has been issued in the form of a parliamentary return, a list (made up to Dec. 31) with the names of every merchant vessel or steamer engaged in the Abyssinian expedition chartered in England, with the net and gross register tonnage of each ship, the horse-power of each engine, the price per ton each ship is chartered at; also the name of each registered owner of such ship as appeared upon the register when the ship was tendered to the Government for hire, and the name of each owner as now stands upon the register, with the name of the broker who tendered such ship. The ships taken up are eighteen:—namely, the "City of Manchester," "City of Dublin," "England," "Queen," "Peruvian," "Kangaroo," "Californian," "West Indian," "American," "Bosphorus" (lost), "Golden Fleece," "Mauritius," "Queen of the South," "Empress," "Parana," "Coumoundouros," "Bolivar," and "Venetian." The gross tonnage is 34,290. The gross horse-power is 4,670. The average rate per ton if discharged at home is 30s. 6d. The rate if discharged abroad varies considerably. It is 45s. per ton in the case of several vessels, and as low as 25s. in one only, the "Parana."

Miscellanea.

THE number of visitors at the Patent Office, South Kensington, for the week ending March 14, was 3,433; total number since the opening of the museum free daily (May 12, 1858), 1,260,322.

THERE are now 63 telegraph stations in New South Wales, and 3,346 miles of wire, costing for construction on an average £45 9s. 9d. per mile. The revenue for 1866 amounted to £30,698. In 1865 there were 138,789 messages, which in 1866 had increased to 145,523.

A CURIOUS fit of rough weather for March set in in the North Riding on the night of Tuesday week when, and during next day, several smart showers with thunder and lightning, occurred. During Wednesday the weather was very wild, and a considerable depth of rain fell.

Digitized by Google

INTELLIGENCE having been received by the directors of the Oude and Rohilkund Railway of the commencement of extended operations on their lines, they intend to issue at an early date a further £1,000,000 of capital in shares of £10 each, to be offered rateably to the proprietors.

A MEETING of the members of the Aeronautical Society of Great Britain will be held at the Society of Arts, Adelphi, on Thursday, March 26, at eight p.m., for the reading and discussion of papers, and generally for the advancement of the society's interests. The Duke of Argyll has consented to preside.

THERE have of late been heavy storms of slete and snow throughout America, blocking up the railways, and causing a general interference with business. An unprecedented amount of snow has fallen this winter, and in some localities snow has lain upon the ground for ninety days continuously.

THE visitors to the South Kensington Museum during the week ending March 14, 1868, were as follows:—On Monday, Tuesday, and Saturday, free, from 10 a.m. to 10 p.m., 10,288. On Wednesday, Thursday, and Friday (admission 6d.), from 10 a.m. till 5 p.m., 1,536.—Total, 11,824 Average of corresponding week in former years, 10,311. Total from the opening of the museum, 7,242,688.

LETTER from Kurrachee state that Sir Seymour Fitzgerald, the Governor of Bombay, has given much satisfaction to the mercantile community of that port by his recent visit, and that hopes are entertained of the speedy completion of the long-delayed harbour works designed by the late Mr. Walker, and of the extension of the Scinde Railway to the Punjab.

MR. R. JONES, of Henfachen, has published a book containing many hundreds of sheep's ear marks. This extraordinary book will be useful to farmers and shepherds from Llangollen to Mawddy. It contains a full description of ear marks for twenty-two parishes around Llanrhaidr. We have seen plenty of books with dog's ear marks, but never before heard of one with sheep's ear marks.

A VOTE of £2,000 having been made for encouragement of manufactures in New Zealand, the Government have had under consideration the offering of a bonus of £1,000 for the first 50 tons of sugar manufactured within the province from beetroot grown in the province, and a bonus of £500 to any person or persons producing 20,000 bushels of marketable malt within the province. It has also been suggested that encouragement should be offered to meat-curing on a large scale.

A CURIOUS point arose on Friday at the Rolls Chambers as to Lord H. Seymour's bequest to the charities of London. His lordship died in 1859, and the definition of London by the Master of the Rolls was not a four mile radius, nor the metropolitan police district, but a "continuous line of houses." An application was made to participate in the fund on the part of the Home for Soldiers' Daughters at Hampstead (within four miles), and the Chief Clerk (Mr. Marshall) refused the application, on the ground that there was not in 1859 a continuous line of houses to the Home.

The "Illustrated Australian News" says:—"One of our enterprising breeders upon the Murrumbiggee, in the neighbourhood of Gundagai, recently experimented upon a fat but otherwise useless horse, as to the profit of boiling down. After the process had been carefully carried out, he realized fifteen gallons of pure oil, that he readily sold at the first offer in Gundagai, for currying purposes, at 6s. 6d. To this is to be added the price of the hide, the value of the hair, the glue from the hoofs, and the bones for manure—all of which would be realized if the process was carried out in a large and systematic manner."

A WRITER in the "Law Journal" complains that nearly every fireplace in each of the comparatively new buildings in the Temple—Paper-buildings, Dr. Johnson's-buildings, and Crown Office-row—is a nuisance to the inhabitant. Some smoke persistently, some at intervals, some when you put on coals, some when they get low for want of coals, some when the window is shut, some when the door is open, and some seemingly only when you are very busy, or bad-tempered. Verily, barristers are a long-suffering and patient race. But why don't they try Mr. Meelie's principle, and remove the chimney pots? If that don't answer, then they should adopt the orthodox remedy of a taller pot surmounted by an elegant cowl. They should consult the architect of the Middle Temple Library on this point.

THE following return of the receipts of the Atlantic Telegraph Cable shows in a remarkable manner the importance of this communication between the Old and the New World to the interests of the mercantile community of England and America. Receipts each day from midnight to midnight compared with those at the corresponding period of last year:—

1868.		1867.

* On this day the land lines of telegraph in Ireland were broken by a gale of wind.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

BOILERS AND FURNACES—2389, 2422, 2425
BUILDINGS AND BUILDING MATERIALS—None.
CHEMISTRY AND PHOTOGRAPHY—2344
CULTIVATION OF THE SOIL, including agricultural implements and machines—2367, 2391, 2426
ELECTRICAL APPARATUS—None.
FIBROUS FABRICS, including machinery for treating fibre, pulp, paper, &c.—2349, 2356, 2364, 2365, 2366, 2374, 2378, 2390, 2401, 2405, 2410, 2411, 2416, 2424
FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—2417
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c—2358, 2359, 2383, 2388
GENERAL MACHINERY—2345, 2346, 2350, 2351, 2354, 2360, 2371, 2373, 2379, 2385, 2363, 2397, 2398, 2404, 2406, 2408
LIGHTING, HEATING, AND VENTILATING—2361, 2414
METALS, including apparatus for their manufacture—2376, 2395, 2420
MISCELLANEOUS—2347, 2348, 2353, 2357, 2363, 2368, 2370, 2372, 2375, 2377, 2380, 2382, 2384, 2386, 2387, 2394, 2396, 2399, 2400, 2418
ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—2355, 2362, 2381, 2392
SHIPS AND BOATS, including their fittings—2352, 2412, 2413, 2415, 2423
STEAM ENGINES—2402, 2419
WARFARE—2369, 2403, 2409, 2421

2342 A. W. WILLIAMSON. *Improvements in lamps.* Dated August 14, 1867.

This invention relates to lamps for burning heavy oils. To burn such oil efficiently, however, it should, as it rises to the burner, and after it has been separated from the bulk of the oil in the reservoir, be highly heated by bringing it in contact with a heated wick tube of some length. To fulfil these conditions, the inventor employs, in order to draw the oil up out of the reservoir, a wick or wicks of large size, which he calls feeders; they are much larger than the wick on which the oil is ignited to form the flame of the lamp, and with the latter or flame wick the feeder wick or wicks are kept in close contact near up to the flame of the lamp.—Patent abandoned.

2344 J. T. WAY. *Improvements in treating phosphate of lime for the manufacture of manure, and for other purposes.* Dated August 14, 1867.

This invention relates to the production from ordinary phosphate of lime, and the use for manure, of a compound of lime and phosphoric acid, intermediate in composition and character between ordinary insoluble phosphate of lime and acid, or soluble phosphate of lime. The details of this invention are very voluminous.—Patent completed.

2345 J. PEACOCK. *An improved machine for cleaning barrels or casks.* Dated August 15, 1867.

This invention relates to the construction of a machine wherein the barrels or casks are cleansed by the centrifugal action of water or other liquid, which action is produced by the rotation of the barrels upon a central axis. The invention consists, chiefly, in the employment of two or more rotating frames arranged to turn upon the same horizontal axis, and adjusted to balance one with the other when loaded. The invention also consists, partly, in the construction of the frames, in the devices for holding the barrels and adjusting them in different positions therein to insure the desired action of the cleansing liquid on all parts of their surfaces, in the means for adapting the rotating frames to receive barrels or casks of various sizes, and for holding a number of barrels evenly balanced during their rotation; also in the devices for locking the frames together, and adjusting and securing them in the position to allow the barrels to be secured and released, and also while they are being filled and emptied. The invention also consists in the construction and arrangement of a trough or vat in combination with the said rotating frames, whereby the barrels can be filled with the cleansing liquid after they are placed in the said frame, and in the arrangement of adjustable valves and tubes whereby the barrels in the frames are all supplied with the liquid at one time—Patent completed.

2346 F. H. WENHAM. *Improvements in heated air engines.* Dated August 15, 1867.

This invention consists in so arranging the top of the cylinder that it shall act as an air pump. In hot air engines the body of air forced into and heated by the furnace must be less in bulk than the capacity of the cylinder, as determined by one stroke of the engine. In order to obtain this condition, according to one method, the patentee provides the top of the cylinder with a sliding or other valve opening to the external air; this serves as the inlet valve of the pump. After the piston has descended to the bottom of the stroke, this valve remains open for a portion of the return stroke, so that some of the air that has just entered is allowed to escape again into the atmosphere. At the time when the air pump contains the requisite charge of air (varying in quantity from three-fourths to one-half the lower capacity of the cylinder) the inlet valve is suddenly closed by the action of the engine, and the contained volume of air is forced through the usual outlet valve into the furnace.—Patent completed.

2347 T. BUSHBY. *Improvements in pill-making machines.* Dated August 15, 1867.

Here the patentee passes the mass from which the pills are to be made between two plain rollers at the distance apart to form the sheet, which sheet is formed into strips or bars by a self-acting knife or grooved rollers, and the bars one after the other fall upon a number of circular grooved cutters. At a portion of the circumference of each grooved cutter there is a stationary grooved cutter, the grooves being opposite each other, forming a circle in transverse section, so that, when revolving motion is given to the circular grooved cutters, the bars shall be cut and shaped into pills.—Patent completed.

2348 J. COSGRAVE. *Improvements in apparatus employed in the heating of bakers' ovens.* Dated August 15, 1867.

Here the inventor employs a chaffer box of the ordinary construction, and supplies air thereto in the usual way. Instead, however, of using a chaffer fitting carefully into the box, he employs one formed with overhanging end flanges, so that, when shipped or set in position, the ends fit over the box and the sides into it. In this way an increased area is obtained through which air may be admitted to the fuel; and that it shall be freely admitted he employs movable bars with apertures therein, and places them longitudinally instead of transversely, as hitherto has been the practice.—Patent abandoned.

2349 R. CLELAND and R. CUNNINGHAM. *A new manufacture of woven fabrics, imitating fabrics woven with horse hair.* Dated August 15, 1867.

This invention consists in weaving "seating" or fabrics for covering furniture and "crinoline," or fabrics for skirts and other parts of wearing apparel, and also other fabrics, with cotton thread, or other suitable spun material, instead of the horsehair hitherto used in weaving such fabrics, the cotton thread or other spun material having the requisite hair-like consistency and glaze imparted to it by process of dressing and polishing.—Patent abandoned.

2350 E. ORMEROD. *Certain improvements in safety apparatus to be employed for preventing accidents in winding coals and other minerals from mines.* Dated August 15, 1867.

This invention relates to a description of link or shackle which is interposed between the winding rope and the cage or receptacle, and which is designed for rendering such attachment either permanent or releasing by self-acting means, according to its position when employed for raising or lowering weights, coal, or other minerals, the said links being so arranged that, in the event of the cage being "over wound," it is released from the rope, and at the same time retained at the point where the link became uncoupled or disconnected. The improvements consist in the employment and use of a link or shackle formed of three plates placed side by side, and connected together at or about the middle of their length by the central pin or stud upon which the plates may turn; in these plates grooves or slots are formed, in which the shackle pins that connect the rope with the cage are contained.—Patent completed.

2351 A. F. BAIRD. *An improved earth closet.* Dated August 15, 1867.

Here the patentee places a receptacle beneath the seat for receiving the deposits with which the earth is to be mixed with a shoot or passage opening into the said receptacle for conveying the earth into the same, and at the other end to that above mentioned another opening by which the earth is supplied from a hopper to the said shoot; the bottom of this hopper being curved and provided with the last-mentioned opening for communication with the shoot, is opened and closed by the action of a sector piece or other valve weighted as a counterbalance, such piece or valve being secured to, and forming part of, a flap or valve hung at the centre, the office of which flap or valve is to close the opening from the shoot into the receptacle first mentioned, the same being effected by means of a projection from the centre of the said flap or valve situate just beneath the seat of the closet, so that, when at rest, the sector valve closes the entrance from the hopper to the shoot, and prevents the discharge of earth into the said shoot; and when the closet is used, the weight of the "sitter" presses the seat on the said projection, and thus gives motion to the valve arrangement and opens the entrance from the hopper to the shoot, shutting the entrance to the receptacle for deposits, thus causing the shoot to be filled up with earth, which is to be discharged therefrom into the receptacle by the removal of pressure of the "sitter" getting up from the seat. The sector valve has a rod or rods attached to it, working in the hopper, to prevent the consolidation of the earth, and cause it to remove as required.—Patent completed.

2352 H. BODART and A. SIGODART. *Improvements in apparatus for propelling vessels.* Dated August 15, 1867.

The objects to be attained by this invention are simplicity of machinery, economy of motive power, and rapidity of action. By means of an axis with three cranks, and driven by a steam engine, or any other suitable motive power, the patentees work three paddles which replace advantageously in every description of vessel the screws and paddle wheels before employed.—Patent completed.

2353 W. R. LAKE. *Improvements in metal ties or bands for securing bales of cotton or other substance.* (A communication.) Dated August 15, 1867.

Here the inventor makes use of ordinary hoop or band iron of the requisite width. The two ends of the band are brought together, and made to overlap each other sufficiently to answer the desired purpose. Slots are cut in the outer overlapping end of the band, and a key is fastened to the other end of the said band. This key is made in a peculiar shape, with one side extending much further from its entire pivot than the other, and the surface of its head is made to incline at an angle of about 10deg. The said key is fastened permanently to the end of the band, and this end is turned back so as to form a double thickness, through which the key passes or it may be made with a washer instead of having the end turned back, the object being to give greater strength to this part of the band.—Patent abandoned.

2354 G. CLARKE. *Improvements in fire-escapes.* Dated August 16, 1867.

This invention has reference to certain well-known fire escapes constructed by the present inventor, and for certain improvements upon which he registered a design on March 12, 1863 (No. 4543). Among the features of the present invention are the following:—One of these improvements consists in strengthening the main ladder against twisting strains by a diagonal wire truss at the back of the ladder, the upper ends of which truss are fixed to the brackets upon the end of the ladder, whence the

Digitized by Google

wire ropes or rods pass diagonally to the opposite ends of the transverse stay bar of the guiding quadrants; here they are led over pulleys attached to the bar, and then again, crossing each other, they pass down to the framing at bottom, to which they are attached by screw bolts arranged so as to be capable of tightening the truss when requisite. Another improvement consists in providing each of the two guiding quadrants for the levers to the fly ladder with three pulleys, instead of one, as heretofore, over which the two side wire trusses are made to pass, so as to render both the quadrants and the side trusses more rigid. Another improvement consists in forming the two levers for working the fly ladder with two arms or "split" levers, to one of which arms the ordinary rope for raising the fly ladder is attached, such rope being worked by a small windlass fixed to the main ladder at bottom, in place of working the rope by hand, as heretofore. To the second arm is attached a check rope, for preventing the fly ladder when raised to the vertical position from falling forward too rapidly. Another improvement consists in substituting for the canvas and wire gauze trough heretofore employed attached to the main ladder a collapsible tube of fireproof canvas netting held open at the upper and lower ends by a framing fixed to the ladder.—Patent abandoned.

2355 J. DAY and W. DORBER. *Certain improvements in the manufacture and construction of cabs, coaches, carriages, omnibuses, and other similar vehicles.* Dated August 16, 1867.

This invention consists in the use of angle or T-iron or steel, or tubular iron or steel, for the framework, and of corrugated metal for the roof and floor, and of tubular metal for the shafts and centre pillar in Hansom cabs, such framework being connected together by metal screw bolts or rivets, and, if required, the whole or part may be galvanized or painted to prevent corrosion.—Patent completed.

2356 M. HENRY. *Improvements in the method of, and apparatus for, treating certain vegetable substances in order to obtain fibrous materials and paper pulp therefrom.* (A communication.) Dated August 16, 1867.

This invention relates, principally, to the treatment of trees and plants of the palm tribe, such as palms, palmettes, chamerops humilis, St. Peter the Martyr palm, cephaglioli, cephaglioni, &c., and consists in subjecting the vegetable substance to two operations in apparatus for the purposes, one process and apparatus being for crushing, triturating, or macerating the vegetable substance, and the other process and apparatus being for combing it.—Patent completed.

2357 H. FRANKENBURG and S. PHILLIPS. *A new or improved fastening, particularly applicable for leggings and gaiters.* Dated August 16, 1867.

This invention consists in inserting a movable button or stud in a piece of steel inserted on one side of the legging or other article to which it is to be fitted, and forming a slot in a piece of steel inserted on the other side of the legging, and which is somewhat curved or bent outwards, always having a tendency to spring from the other side, by pressing the slot over the button, and by turning the latter the fastening is secure.—Patent abandoned.

2358 R. JOSEPH. *Improvements in stays or corsets.* Dated August 16, 1867.

Here the inventor makes each half of the stay in two pieces in the depth, the lower piece being about half the depth of the upper one, and, instead of cutting the material straight, as usual, he gives it a curved form or outline, the lower edge being cut much wider than the top, and deeper also at the ends than in the centre of the curve. Two of these curved pieces are employed, one for each lower half of the stay, and are sewn to the upper part, the lower edge of which is cut to the curve of the piece to be attached thereto. In this manner the lower part of the stay will have sufficient fulness to readily adapt itself to the form of the hip without the aid of gores. The upper part of the stay is made in a similar manner to the bottom part.—Patent completed.

2359 T. JACKSON. *Improvements in pianoforte actions.* Dated August 16, 1867.

In order to obtain the escapement in a pianoforte action—that is to say, in order to cause the point of the fly or hopper at the moment that the blow is struck to escape on to the inclined part of the lever or instrument on which it acts, so that the hammer may not be blocked against the string, or so close to it as to cause a second blow to be struck upon it, the inventor mounts on the block which carries the fly or hopper a bent lever; this lever is jointed to the block at a point intermediate of its length, and when the finger key is depressed the outer end of the lever, or, rather, an adjustable button upon it, is brought up against a fixed stop or rail just at the time when the escape is required. The bent lever is then caused to turn on its centre, and its other end acting on a button on the fly or hopper pushes it off.—Patent abandoned.

2360 J. W. DUDLEY. *Improvements in machinery for cutting corks.* Dated August 16, 1867.

In machinery constructed according to this invention, the sheet of cork is first cut into strips of the width required for the length of the cork, and is of a thickness more or less approaching the diameter of the corks required. The strip of cork is fed between two dogs which grip it; a knife then comes forward and cuts off a piece from the strip sufficient for making one cork. Immediately following the knife first mentioned, and in the same plane, is a second knife not quite so wide as the first, but of great length, and shaped like the segment of a circle; this knife is mounted on arms which converge to the centre of the segment, and are there connected to an axis on which it moves working in a suitable bearing. The curved knife is capable of reciprocating movement, oscillating from its centre, so that its edge is always presented to the piece of cork cut off from the strip. This piece of cork is held between the two dogs, and so soon as the curved knife commences to cut it, a lever arm mounted on the framing actuates the dogs by suitable gearing, causing them to revolve the piece of cork against the edge of the curved knife as it travels along, thus rendering the cork cylindrical. When the curved knife reaches the end of its course, the cork now finished is released from the dogs by a lever arm acting on one of the dogs, and falls into a shoot or receptacle; the lower end of this lever arm is connected with a cam by which it is operated, the other end acting upon one of the dogs for releasing the cork. During the return movement of the knife-carrying frame, the lever arm is returned to its original position by the cam above mentioned, at the same time holding open one of the dogs for again receiving the strip of cork, a piece of which is cut off and turned as before. The oscillation of the knife frame is produced by a connecting rod attached thereto at a suitable distance from its axis, motion being transmitted to the connecting rod by gearing, the whole being operated by any suitable motive power. The patentee also provides two grindstones, which are kept continually rotating by the gearing operating the connecting rod. At each oscillation of the frame the edges of the curved knife come in contact with the revolving pieces of the grindstones, and it is thus always kept in a sharp condition. By simply lowering and slightly altering the direction of one of the dogs, a taper cork is produced. The knife frame can be adjusted on its axis at any distance from the dogs, according to the size of the cork required, and can be made to move to and fro in order to produce an oval cork.—Patent completed.

2361 J. WAVISH. *Apparatus applicable to the heating of greenhouses, causing bottom heat to plants, and other heating purposes.* Dated August 17, 1867.

This apparatus for heating greenhouses consists of a peculiar arrangement of stove and hot water or liquid boiler, such stove being devised and adapted for being heated by lamps burning mineral or other oil, or lamps or burners of any similar character.—Patent abandoned.

2362 A. LEVESON. *Certain improvements in hoods or coverings for perambulators, bath chairs, carriages, and other vehicles.* Dated August 17, 1867.

This invention consists in the application of a coiled wire or plate spring to the pivot or centre pin of the hinge joint on which the hood turns, when being raised or lowered, or in the application of india-rubber or other spring to the front frame of such hoods, so arranged that the hood shall be raised thereby and opened and held in such position when it is released from a strap or cord which retains it in its folded position, so that the spring forms a self-acting hood lifter, or opener and retainer.—Patent completed.

2363 L. AVOYNE-BAINEE and M. J. SIBILLAT. *A new system of metal spring mattresses.* Dated August 17, 1867.

This spring mattress is formed entirely of iron. In its most simple construction it receives its elasticity simply from two helical springs, or even from a single plate spring, such as those upon which carriages are suspended.—Patent completed.

2364 A. LEES and W. H. RHODER. *Improvements in machines for spinning and doubling cotton, wool, and other fibrous substances.* Dated August 17, 1867.

This invention is applicable to the machines for spinning and doubling, called self-acting mules, and it consists, first, in an improved change motion applicable to the cam shaft. This motion is composed of an internal ratchet wheel keyed on the shaft passing through the hollow cam shaft, to which is hinged a catch which is brought alternately into gear at opposite sides of the said ratchet wheel by a pair of sliding rods, acting, when required, on a swell fixed to the catch above referred to. These sliding rods are actuated at the end of the stretch, and, when the carriage has run in, by stops on the usual side rod.—Patent completed.

2365 T. SAGAR and T. RICHMOND. *Improvements in looms for weaving.* Dated August 17, 1867.

This invention relates to the "letting off" motion of looms, and has reference to a former patent, dated July 4, 1866 (No 1775). It consists in dispensing with the catches and ratchet wheels described in the former patent, and in using in lieu thereof the following parts:—To the axle of the usual vibrator the inventors fix a toothed segment or lever with a stud or studs; the teeth of this segment, or the studs of the lever, take into the teeth of a wheel, on the boss of which is a pinion gearing into a wheel on the axle of the warp beam. When the tension of the warp depresses the vibrator, the tooth of the segment, or the stud of the lever, is raised, and allows one tooth of the wheel in which it gears to slip, thereby letting off a portion of the warp; the parts remain in these positions until the tension of the warp depressing the vibrator again allows another tooth to slip, and thus the warp is let off as required. The teeth of the segment, or the studs of the lever, and the teeth of the wheel in which they work, are, or may be, case hardened, or made of hardened steel. The second part of the invention consists in tightening the warp when the reed is beating up the weft by an eccentric on the crank shaft acting on a lever to which the vibrator is connected; or by connecting the lay sword, or the lay, to a lever loose on the axle of the vibrator, in the upper arm of which lever is a set screw, against which the vibrator presses when the reed beats up; or the same result may be obtained by connecting the lay or the crank shaft by other equivalent to the vibrator.—Patent abandoned.

2366 J. HOLROYD and W. FIELDHOUSE. *An improved method of twisting or doubling yarns in mule spinning machinery.* Dated August 17, 1867.

The object here is to produce yarns with an irregular twist at stated intervals upon mule frames. This irregular twist is effected by dispensing with the usual motion to the drawing or delivery roller, and by causing it to pause at given periods in its revolutions whilst delivering the yarn to be twisted, such period being dependent upon the space required between each irregularity, the intermediate space presenting the ordinary spiral twist.—Patent abandoned.

2367 M. FROW. *Improvements in reaping machines.* Dated August 17, 1867.

This invention consists in a mode of arranging the gathering and sheafing parts of reaping machines, and in constructing additional parts thereto in such a manner that one or more of the raking boards will gather the growing crop towards the cutters, and deposit it upon the table or platform when cut; and also that one or more of the raking boards will, in addition to gathering the growing crop as above stated, also deliver the cut crop off the table or platform in quantities suitable for sheafing.—Patent completed.

2368 A. M. CLARK. *Improvements in the construction of moulds for casting aluminium and other metal plates for artificial teeth, also in the method of casting said plates and securing the teeth therein, and in apparatus connected therewith, part of which improvements is applicable for producing other fine metal castings.* (A communication.) Dated August 17, 1867.

This invention is not described apart from the drawings.—Patent completed.

2369 J. W. DIXON and W. BUTTERY. *Improvements in apparatus for turning or closing cartridges for breech-loading firearms.* Dated August 17, 1867.

Here the patentees employ a tube or barrel of such a size as to receive the cartridge case freely; it is usually made in one piece with a jaw and an arm carrying a binding screw, by which the apparatus may be clamped to a table opposite. One end of the tube or barrel is a hollow cone capable of being rotated by a crank handle, and whilst it is thus turned, the cartridge case to be closed is pressed against it by a lever rammer entering the other end of the tube or barrel, and bearing against the base of the cartridge, and so the case is closed. Afterwards it is expelled by a rammer passing through the closing cone or instrument. The invention, however, consists especially in the way in which the cartridge case is prevented rotating in the barrel or tube whilst the closing cone or instrument is acting upon it. The patentees form a longitudinal slot in the tube or barrel, and into this slot they insert a button or stud with teeth upon it on the end which projects into the tube or barrel. The button or stud has a flat head on which a strong spring presses. As the cartridge is pushed up the barrel or tube, the teeth of the button or stud engage with its base, and whilst the button or stud prevents the cartridge case turning, it travels with it towards the closing cone or instrument. It is driven back with the cartridge when the turning or closing is complete.—Patent completed.

2370 F. B. HOUGHTON. *Improvements in treating products obtained when operating on wood and other vegetable substances to obtain fibre therefrom.* Dated August 17, 1867.

The patentee claims evaporating the spent alkali which has been employed to boil wood or other vegetable substance to obtain fibre in a pan heated by a coil of seated water pipes contained partly within the pan and partly within a furnace, as described.—Patent completed.

2371 W. W. POCOCK. *Improvements in indexes or tell-tales applicable to fluid meters and other counting or measuring apparatus.* Dated August 17, 1867.

This invention is intended to show the amount of money due for gas burnt during any given period, or the amount of money received at the entrances of public places, &c., and it consists, mainly, in the addition to the train of wheels usually employed for measuring and counting of other wheels the spindles of which carry discs marked with figures to indicate pounds, shillings, and pence, one figure upon each such disc being visible at all times through an aperture corresponding with such disc in the face of the apparatus, or otherwise.—Patent completed.

2372 M. CAHEN. *An improved apparatus for sealing letters, envelopes, and other papers.* Dated August 17, 1867.

This invention is not described apart from the drawings.—Patent completed.

2373 W. R. GOULTY. *Improvements in machinery for cutting, crushing, bruising, or otherwise preparing furze or gorse, straw, bark, or other vegetable substances.* Dated August 17, 1867.

The patentee claims the arrangement of a series of revolving spiral or parallel cutting surfaces in combination with revolving pressing or crushing surfaces so driven as to have a shearing as well as a pressing action upon the vegetable materials to be cut crushed or bruised as they are caused to pass between them, in the manner described.—Patent completed.

2374 T. TUNSTILL. *Improved means and apparatus for preparing size for warps or other purposes.* Dated August 19, 1867.

This invention consists in the use of a boiling vessel or pipe placed, by preference, in or near a vertical position, having an inlet at bottom and outlet at top. A steam pipe is introduced through the top which extends to near the bottom of the vessel, and having perforations therein. The usual mixing vessel is employed, and an ordinary force pump is connected thereto and to the inlet of the boiling vessel. The pump draws the size from the mixing vessel and forces it into and gradually up the boiling vessel or pipe through the outlet into another vessel for supply; or it may be conducted from the outlet direct to the sizing machine. Steam at high pressure is forced through the perforations of the central pipe, which mixes and combines with the size, whereby it becomes thoroughly boiled in its passage therethrough. A tap or valve is applied to the outlet for closing the same and regulating the quantity and time of discharge, and a pipe with a weighted valve is also connected to the inlet pipe for returning the surplus quantity forced by the pump back into the mixing vessel.—Patent completed.

2375 J. CRONIER. *An improved rotary heel for boots and shoes.* Dated August 19, 1867.

This rotary heel is made of leather adapted by a metal plate well riveted to the heel, the same having a round hole for a screw or screws to pass through to an interior plate of a smaller size from the inside of the boot or shoe, not interfering with rotatory movement, part of the heel giving facility to be repaired, the same as any ordinary boot or shoe.—Patent abandoned.

2376 W. B. ADAMS. *Improvements in uniting and treating iron, steel, and other metals in sheets, plates, rails, or other forms, applicable to navigable vessels, forts, guns, bridges, or like structures.* Dated August 19, 1867.

We cannot here give space to the details of this invention.—Patent abandoned.

2377 J. HOOKER and F. BRABY. *Improvements in fire-lighters, also applicable for fuel generally.* Dated August 19, 1867.

This invention consists, essentially, in the use of "napthlin" in the preparation or manufacture of fire-lighters; it is also applicable to fuel generally.—Patent abandoned.

2378 C. E. BROOMAN. *An improved mode, or improved means, of colouring or ornamenting fabrics and other surfaces, and of preparing printing surfaces.* (A communication.) Dated August 19, 1867.

This invention mainly consists in applying upon fabrics and other surfaces to be coloured or ornamented a liquid in a state of fine mist, or very fine spray—that is to say, in the state of extreme reduction or of pulverization, such liquid containing colouring matters or substances, which will colour or ornament the fabric or surface.—Patent completed.

2379 W. E. NEWTON. *Improvements in crank motions.* (A communication.) Dated August 19, 1867.

The object here is to avoid the "dead points" and "dead centres" of a crank motion, and to make the power that drives the crank available during the whole or any part of the rotation of the crank. The invention consists

Digitized by Google

in the use of two connecting rods working on one crank, and at nearly or right angle to each other. They are connected within an oscillating frame, and are furnished with catches and let goes, so that they will at the proper time and place, by self-connecting with and self-detaching from the crank, will take hold of and let go alternately, and at such angle of the crank with regard to its crank pin and shaft or journals as will most readily apply or transmit the propelling power to it.—Patent completed.

2380 F. and G. PARKES. *Certain improvements in spades and shovels.* Dated August 19, 1867.

In the manufacture of an ordinary shovel, where langets are required, these improvements consist, not in forming the langets out of the two pieces of steel or iron combined composing the blade of the shovel, but in raising both thicknesses into a ridge down the middle, which the inventors purpose connecting simply to the part raised, and welding the two thicknesses of metal right up to the raised or corrugated part, by which means a large amount of additional strength is given to the lengthway of the blade of the shovel, as also to the langets, which form a continuation of the raised or corrugated part. Second, the improvements apply to screening shovels, or like implements, in which case the langet is formed with the back or main part of the shovel; and by preference they use steel, more particularly for the part of the langet denominated the "coffering," where it unites and forms a part of the back for the sake of obtaining additional strength and lightness.—Patent abandoned.

2381 C. REISERT. *Improvements in railway carriages.* Dated August 19, 1867.

This invention comprises many features, the details of which are too voluminous to be produced here. One part of the invention consists in completely isolating railway carriages from their frames. Another in the employment of a species of double springs.—Patent completed.

2382 E. A. COWPER. *Improvements in the construction of safes for containing articles of value.* Dated August 19, 1867.

This invention consists in forming safes of wrought-iron plates welded together, or of compound plates of wrought iron and steel first welded together and formed into plates, and then welded together to form the safes, and the inventor also rolls such plates with a thick edge or projection, or with a recess or rabbit to facilitate the welding up of the edges of the plates, and to prevent them from being too much cut away by the action of the welding fire.—Patent abandoned.

2383 A. MARTIN. *Improvements in apparatus for uniting the brims to hat shapes or foundations.* Dated August 20, 1867.

Here the edges of the brim and crown are damped and placed on a block in the usual way. This block is placed in a screw or lever press, to which is attached a metal ring or hoop, similar in form to the hat, and the lower edge of which corresponds with the curve of the brim. This ring or hoop is heated by means of small gas jets impinging on its surface from a pipe provided with perforations attached to and encircling the said hoop, which pipe is connected by a flexible tube with the source of supply. In order to unite the brim to the hat-shape the ring is brought down by the action of the screw or other press so as to tightly embrace the blocked shape, its lower edge compressing the lapping edges of the brim and head-piece, the heated ring at same time effecting the drying of the uniting joint, while the starch or other adhesive matter contained in the material causes the two parts to adhere firmly together.—Patent abandoned.

2384 W. BURROW. *An improved rack for mineral or aerated waters, or other liquids in bottles.* Dated August 20, 1867.

This rack is constructed as follows:—An upright standard at each end is provided with a number of horizontal arms (say six) upon each side, and the ends of these arms are respectively connected together by horizontal rods or bars, each rod or bar being of sufficient length to support (say) six bottles without touching each other; between each pair of horizontal rods (and also connecting the two standards together) is a plate of the same length as the rods placed on edge, and perforated with (say) twelve holes to receive the necks of the bottles. The bottles are placed in the rack with the corks inwards and their necks through the perforations in the plates, the thick part of the body near the base resting on the horizontal bars, and the neck being lower than the body, each alternate bottle being reversed in position, so that when the rack is full there are (say) six layers of one dozen each.—Patent completed.

2385 W. DIXON. *Preservation of life from fire, or raising or lowering persons or goods from buildings.* Dated August 20, 1867.

This invention consists in placing a ring or eye-bolt over the windows of houses, and to which this portable apparatus can be attached. The apparatus consists of a block with hook and spring clip, which may be connected at pleasure with the eye-bolt above; through this block runs a rope, to one end of which is attached a pulley or snatch block, the other end of the rope passing underneath the sheave, and thence to the person working the apparatus. To the pulley or snatch block is attached a cradle or chair for the removal of persons, or hook and rope for goods.—Patent abandoned.

2386 H. CRIDLAND. *Improved applications to be used for removing the wool or hair from the skins of animals.* Dated August 20, 1867.

Here the patentee uses a solution of potash or soda, separately or in conjunction, of such strength as the thickness of the skin or hide may render requisite. He paints the flesh sides of the skins therewith. This causes the speedy severance of the wool from the skin, avoids the injurious action caused by the use of lime, as well as its after presence, and leaves the pelt or skin more bulky in appearance.—Patent completed.

2387 A. S. STOCKER. *Improvements in bottles, and in the manufacture of caps or covers for the same.* Dated August 20, 1867.

This invention consists in lining such or other caps or covers having screws, or their equivalents, formed in their inner peripheries with a thin soft metal such as will yield and take the inside figure thereof when pressure is applied thereto. The invention relates to a former patent granted to the present patentee, dated March 26, 1867.—Patent completed.

2388 A. COHEN. *Improvements in watches.* (A communication.) Dated August 20, 1867.

The patentee claims, first, the general construction and arrangement of mechanism for winding up watches, and setting the hands thereof, as described. Second, the combination with the hinge of a watch case of mechanism for operating upon the main spring, and effecting the winding of the same by the act of opening and closing the case. Third, the combination of a toothed rack in gear with a ratchet wheel on the axis or spindle of the main spring of a watch, and jointed to the end of a lever which derives its motion from the hinge of the watch case, the whole operating substantially as and for the purpose described. Fourth, the connecting the main spring with a friction piece or bridle fitted inside the barrel in lieu of to the barrel itself, substantially as and for the purpose described Fifth, the peculiar combination of mechanism for setting or adjusting hands of what are known as keyless watches, as described.—Patent completed.

2389 J. MURGATROYD. *Improvements in the construction of steam boilers, and apparatus connected therewith.* Dated August 21, 1867.

In constructing boilers having the firegrate under a projecting end, and the roof of the fireplace connected to the upper part of the boiler, or in any other boilers having the firegrate within the cylindrical casing, it is very desirable to form the roof part over the fire so as to be self-cleaning, and also so that no rivets be exposed to the action of the fire. In order to effect these objects the patentee makes each plate of the whole length of the firebox or roof part over the fire, and without any cross joints; these plates are fixed in an inclined position. The longitudinal connections of these plates are secured by rivets placed in the internal part of the boiler.—Patent completed.

2390 W. BOSTOCK. *Improvements in spools, reels, or bobbins, and in the method of manufacturing the same.* Dated August 21, 1867.

In the case of spools, the ends of which are formed separately from the barrel, and of the same or a different material, and are afterwards attached to the barrel, the patentee removes a portion of the wood from the centre of the barrel by boring, so as to form a cylindrical hole through the barrel of larger diameter than is ordinarily made to suit the spindles of the winding machines, the thickness of wood in the barrel after being bored being sufficient only to give a suitable strength to the barrel. The ends he forms of wood, bone, metal, &c., by turning an annular groove in one side of each "end" of a suitable size to fit the end of the barrel, the said "ends" being otherwise formed to give a suitable appearance to the spool, and to enable the smoke to be filled in the ordinary machines in the usual manner. The ends are attached to the barrel by forcing the ends of the barrel into the annular grooves in the "ends," either with or without the application of glue, &c., washers of thin calico being interposed between the barrel and the "ends," if preferred.—Patent completed.

2391 C. E. HALL. *Improved means or apparatus for hoeing, thinning, or chopping out turnips or any other root crops requiring such process.* Dated August 21, 1867.

This invention is not described apart from the drawings. —Patent completed.

2392 W. THOMAS. *Improvements in apparatus for registering the number of passengers carried in omnibuses.* (A communication.) Dated August 21, 1867.

Here the manner in which the registration is accomplished, so as to secure proper indication of the number of passengers carried during a day, or other longer or shorter period, is by the conductor moving a certain handle whenever a passenger enters or leaves the omnibus, or at a particular part of the journey; or, if desired, the passengers may move the handle. The movement of the handle is conveyed by certain transmitters to a registering apparatus, which, each time it is moved, causes the next higher consecutive number to appear, and, at the same time, to sound a bell, or give an audible signal.—Patent completed.

2393 J. ROBINSON and J. SMITH. *Improvements in applying motive power to saw frames.* Dated August 21, 1867.

This invention consists in arrangements whereby the patentees are enabled to drive saw frames by the direct action of steam, air, or gas cylinders. First, they use the steam, air, or gas as an elastic abutment for the piston, and this they effect by admitting steam, air, or gas to the cylinder before the piston has completed its stroke. The elastic fluid, therefore, exerts a resistance to the impetus of the piston and saw frame, but, at the same time, yields thereto so as to constitute an elastic abutment.—Patent completed.

2394 G. LUYCKX. *Improvements in the manufacture of waterproof tubes.* Dated August 21, 1867.

One mode of manufacturing tubes in accordance with this invention is as follows:—A seamless tube is, in the first instance, constructed of hemp, flax, &c., and of any desired length, the same being rendered durable by being tanned with oak bark, either by a hot or cold process. A sufficient quantity of caoutchouc in solution is then introduced into the interior of the tube to thoroughly impregnate the substance of which it is made. This the patentee effects by passing the tube between a pair of rollers. He then makes a roller or cylinder of sheet india-rubber, prepared, but not fully vulcanized, the same being of a less diameter than that of the tube of hemp, &c., and into which it is introduced. Each end of the tube is then drawn over or otherwise secured to the nozzle of a cock provided with a key for opening or closing it. One of these cocks is connected by a union joint to a pipe leading from a steam generator or source of steam. On the last mentioned cock being opened, a jet of steam is admitted into the india-rubber tube, which causes it to expand, and by very gradually increasing the pressure and the heat, a degree of vulcanization is obtained sufficient to perfect the adhesion of the two substances, so as to render them inseparable. The cock at the opposite end of the tube is kept closed when the steam is first admitted into the tube, but is opened occasionally during the process to allow of the escape of any condensed vapour.—Patent completed.

2395 C. W. SIEMENS. *Improvements in furnaces, and in apparatus in connection therewith, principally applicable to metallurgical operations.* Dated August 21, 1867.

The patentee claims, first, making cast steel upon the open hearth of a furnace by effecting simultaneously the reduction of iron ores in vertical heated hoppers, and the dissolution of the reduced metal, without exposing it to the flame in the metallic bath provided in the furnace. Second, making cast steel upon the open hearth of a furnace by causing wrought iron, steel, or white cast iron, to descend upon inclined planes, or through hoppers, where they become gradually heated into a fluid bath of cast iron under the influence of very intense heat, where they are dissolved and converted into cast steel. Third, applying regenerative gas furnaces to the operations set forth in the first and second claims, in such a manner that a portion of the products of combustion are withdrawn to heat the materials descending into the service by gravity, while the remaining products of combustion which have not been reduced in temperature by contact with cold materials pass through generators to the chimney in the usual manner, the effect being that the temperature of the furnace is not reduced by the introduction of such cold materials. Fourth, he claims, in combination, the general details of construction and management of the improved furnaces, substantially as described. Fifth, constructing kilns for calcining ores, limestone, cement, and plaster of Paris, wherein the required heat is produced by the combustion of air with gaseous fuel made to enter the kiln both centrally and at the circumference at some distance above the openings through which the air enters, substantially as described.—Patent completed.

2396 J. SAINTY. *Improvements in hurdles, lifts, and fencing for agricultural and other purposes.* Dated August 21, 1867.

This invention consists in the use of pieces of wood and iron made in different lengths, each length being constructed of two heads, and two or more longitudinal bars of wood, the heads being mortised to receive the end of each bar, which is tenoned down to a shoulder to fit each mortice in the head. The wood bars are secured into the heads by iron rods passing through each head, forming of themselves additional bars, and, by machinery, the wood bars are forced into each mortice of the head, and secured by the iron rods or wire being coiled round each head of the lift or fencing, and secured by a twisted joint. Each lift or length of fencing is provided with struts or braces nailed into the wood bars at different spaces, and each iron rod is secured to each strut or brace by iron staples. —Patent abandoned.

2397 J. GOUCHER. *Improvements in an apparatus for preserving life in water, and propelling, floating, or manœuvring in water any body, vessel, or mechanical contrivance, and for floating or manœuvring in the air any mechanical contrivance.* Dated August 21, 1867.

This invention is not described apart from the drawings. —Patent completed.

2398 J. M. NAPIER. *Improvements in coining presses* Dated August 21, 1867.

This invention consists in the application of hydraulic pressure exerted through a force pump, or other means, upon a ram or piston, and so employed as to bring the coining dies forcibly to act upon, and impress, blanks supplied in succession to them. To separate the dies, and allow the piece last under pressure to be displaced, and a fresh blank introduced, the patentee provides valves, by actuating which the flow of the water may be reversed and caused to act upon the opposite side of the piston, where the area is less, and so withdraw it while the water on the other side of the piston is at the same time forced out of the cylinder through a valve which is opened to admit of its egress.—Patent completed.

2399 J. MANGNALL. *Improvements in elastic mattresses* Dated August 21, 1867.

This invention consists in using vulcanized rubber in combination with wooden or other laths or bearing pieces, the elasticity of the rubber being called into play by extension, and not compression.—Patent completed.

2400 T. WIDDOWSON. *Improvements in the manufacture of umbrellas and parasols.* Dated August 21, 1867.

The object here is to dispense with the two wire springs usually employed to hold the umbrella or parasol in its open and in its closed position. To hold the umbrella in its open position the patentee employs a spring catch fastened to the outside of the stick, and catching against the edge of the runner, the said catch being released (when it is desired to close the umbrella or parasol) by pressing it outwards with the thumb or finger. In order to hold the umbrella or parasol in its closed position, he fixes the runner which carries the stretchers to the inner end of a tube, and to the other end he attaches a second tube or ferrule capable of sliding a short distance, and acted on by a spiral spring; this second tube or ferrule is slightly bell mouthed. When the umbrella or parasol is closed, this tube is drawn upwards (or towards the handle), compressing the spiral spring, and the points of the ribs are pressed round the stick under the bell mouth; the tube being now released, the spiral spring forces the tube slightly downwards (or from the handle), and the bell mouth holds the points of all the ribs, and prevents the umbrella or parasol from opening. When it is desired to open the umbrella or parasol, all that is necessary is to withdraw the bell-mouthed tube from the points of the ribs, and slide the runner up till the spring catch holds it. —Patent completed.

2401 A. SMALLEY, B. CROASDALE, and W. L. L. LEAVER. *Certain improvements in looms for weaving.* Dated August 22, 1867.

This invention consists in making the back bearer elastic, and in dispensing with the weights and levers used in weighting the yarn.—Patent abandoned.

2402 T. SAULT. *Improvements in slide valves.* Dated August 22, 1867.

This invention relates to means for preventing friction between a slide valve and its seat or bearing, and the consequent wearing of the surfaces of the same, and the improvements consist, chiefly, in supporting the valve upon rollers provided with means for adjustment, whereby the proximity of the said valve to its seat can be regulated with great facility and accuracy.—Patent completed.

2403 J. NEWARK. *Improvements in breech-loading firearms* Dated August 22, 1867.

This invention relates to those kinds of breech-loading firearms in which the breech end is opened for loading and closed for discharge by a block or closer hinged to the breech end of the barrel, and the invention consists of the arrangement or combination of parts hereinafter described for fastening down the hinged blocks, and actuating the discharging pins or strikers of the said firearms. The patentee arranges or combines the parts in the following manner:—The block or closer by which the breech chamber or chase of the gun or rifle is opened and closed may be hinged to either side of the breech chamber, or to the end of the barrel, and in the axis of the said block is a pin or striker by which the gun is discharged. He introduces into the tail pin or rear end of the breech chamber or chase a piston or sliding bolt, which is of the size of, and situated in a line with, the pin or striker in the axis of the hinged block. This piston or bolt is pressed inwards by

Digitized by Google

a coiled spring so as to lie flush with the face of the tail pin. On about the middle of the axis of the tumbler of the lock, and behind the head of the piston or bolt described, a cam or arm is fixed, or the said cam or arm may be made in one piece with the said axis. When the cartridge has been introduced into the barrel of the gun or rifle, and the hinged block has been shut down into the breech chamber, by pulling the trigger of the lock the cam or arm described on the axis of the tumbler is made to act upon the head of the piston or bolt in the tail pin and project it towards the muzzle of the gun or rifle. On the advance of the piston or bolt, it is made to strike the pin or striker in the hinged block and explode the cartridge and discharge the gun or rifle, and at the same time, by entering the hole in the block in which the pin or striker works, to effectually fasten down the block during the discharge of the gun or rifle. When it is wished to reload the gun or rifle, the cam or arm is lifted from the head of the piston or bolt in the tail pin by a lever fixed on the axis of the tumbler, and situated in front of the lock plate. On removing the cam or arm from the piston or bolt, the latter is withdrawn from the hinged block into the tail pin by its coiled spring. The hinged block may now be raised for reloading. The exploded cartridges may be removed from the barrel on opening the breech by an extractor attached to the joint of the hinged block, or worked in any other convenient manner.—Patent completed.

2404 S. LYNES. *An improved self-acting lubricator.* Dated August 22, 1867.

This invention has for its object the lubricating of the necks or bearings of shafting by a simple and self-feeding method, which economizes the use of oil, and dispenses with constant attendance. In proximity to the neck of a shaft the patentee affixes to the bracket carrying the same a smaller bracket, by which he supports two small rollers one above the other, the lower one having a groove cut in its centre in the circle of its rotation, and receiving motion through a grooved pulley on its axis by a band of cotton, tow, india-rubber, &c., driven by the shaft to be lubricated. Pinion wheels are secured to the axis of both rollers, consequently the lower one drives the upper one. An oil feeder and receiver are placed under the neck into which a supply of oil is poured, and by means of a band passing between the two rollers named, and around a friction roller placed in the bottom of the oil receiver, the oil is carried upwards, and being squeezed out between the rollers falls into a spout placed underneath them, and is conducted to the neck. By this means the oil is kept in constant circulation, as it no sooner drops from the neck of the shaft into the receiver that it is again carried upwards upon coming in contact with the band.—Patent completed.

2405 R. KING, J. LOWDEN, and W. GARTSIDE. *Certain improvements in carding engines.* Dated August 22, 1897.

The patentee claims, first, the novel application and use of a roller or rollers partly covered with cards employed to "strip" or clean the doffing cylinder in carding engines, and having an intermittent slow and accelerated revolution effected by the aforesaid means, or other mechanical equivalent, and also the combination therewith of a reciprocating or constantly revolving comb to clean the said partly covered stripping roller, Second, the novel arrangement of "cards" on cleaning rollers (as shown), whereby the teeth or "cards" enter the "card" surface to be stripped whilst moving in the same direction as such surface, but at a reduced speed, instead of the teeth being opposed and moving in reverse directions (as hitherto), as described.—Patent completed.

2406 W. NEWSOME. *Improved apparatus for cutting or forming metal joints.* Dated August 22, 1867.

This invention is designed for the purpose of cutting or forming the working faces of metal joints, and consists of an instrument or tool having four discoidal cutters, and adapted to be used either in an ordinary lathe, or to be worked with a lever as a ratchet brace.—Patent abandoned.

2407 D. HOWARD. *Certain improvements in the manufacture of fabrics termed union flannels, and in other similar union fabrics.* Dated August 22, 1867.

This invention consists in weaving "union fabrics" from warps consisting of all woollen fibres, and from weft which is composed of all cotton fibres, such warp and weft being woven or employed either in a dyed or undyed state.—Patent completed

2408 A. M. CLARK. *Improvements in apparatus for raising water or other liquids by steam power.* (A communication.) Dated August 22, 1867.

This invention consists in the use of a floating piston within a stationary cylinder, the piston being alternately depressed by the steam and elevated by the water, the steam being condensed by the water as soon as the piston is down, so that thereby the piston is relieved from the pressure of the steam, and is free to be acted upon by the water. With a proportionately small amount of steam power a large column of water can, by these means, be elevated to a considerable height.—Patent completed.

2409 J. JONES and F. J. JONES. *Improvements in cartridges for breech-loading firearms.* Dated August 22, 1867.

We cannot here give space to the details of this invention. The patentees claim, first, the arrangements or combinations of parts constituting a self-acting valve, or self-sealing gas check, substantially as described. Second, the arrangements of a short additional wrap of metal or other material, such additional wrap being of a part or piece with that forming the structure of the tube or case, and the mode or process of cutting the material for the same, so as to avoid waste. Third, the arrangements or combinations of and for attaching the barrel, tube, or case to the head independently of its being compressed into the hollow rim or shoulder of the head. Fourth, the arrangements or combinations of parts for compressing the case of the cartridge into the hollow rim of the head, substantially as described. Fifth, the arrangements or combinations for placing and retaining the anvil within the percussion cap, substantially as described. Last, the application of any or all the foregoing arrangements or combinations, or any mere modifications thereof, to all descriptions of "self-ignition" cartridges.—Patent completed.

2410 J. G. MARSHALL. *Improvements in solvent or detergent processes.* Dated August 22, 1867.

This invention relates to a mode of combining the influences of high temperature and great pressure in solvent or detergent processes, to be applied to dissolving the gummy or resinous matters adhering to the fibres of various fibre-yielding plants, or for cleaning fibrous material of animal origin, such as wool or silk, from extraneous matters that may be adherent thereto. The patentee effects these objects by enclosing the material, fibres, or fabric to be operated upon in a closed vessel or chamber of a shape and strength suited to resist the amount of internal pressure that is intended to be employed to force the solvent or detergent liquids through the fibres when the goods to be operated upon are arranged in the vessel. —Patent completed.

2411 H. HIGGINS and T. S. WHITWORTH. *Improvements in machinery for preparing cotton and other fibrous materials for spinning.* Dated August 22, 1867.

This invention relates, first, to those carding engines in which a series of flats is mounted upon a travelling chain, and consists in an arrangement whereby the grinding of the flats is regulated by the surfaces which register them when they are in operation for carding. Second, the inventors attach the chain which carries the flats to one side thereof, instead of to the middle, as is usual. Third, the invention relates to carding engines in which the flats are moved forward and are individually carried back. In machines of this class they cause the flats to pass in contact with stripping and grinding surfaces, and they propose to use a stripping and grinding arrangement similar to that for which provisional protection has been granted to J. Higgins, dated April 11, 1867 (No. 1079). Fourth, the invention consists in a method of supporting top cards or flats. Another part of the invention relates to the slubbing or roving frame, and consists in methods of adapting the flyer to the spindle.—Patent abandoned.

2412 T. W. LAWSON. *Improvements in the construction of ships and vessels.* Dated August 22, 1867.

This invention consists in constructing the bottoms of ships and vessels concaved longitudinally, the concavity extending only to where the floors begin to rise at each end, thus admitting at the same time of a fine run and entrance.—Patent completed.

2413 J. M'INTYRE. *Improvements in the mode of covering and protecting iron plates from the action of sea-water.* Dated August 22, 1867.

This invention consists in fastening on to the plates to be preserved sheets of Muntz's metal, zinc, copper, &c., in the manner hereinafter described:—The patentee fixes by screws or rivets to the iron plates strips of metal, so formed in the cross section as to leave grooves to admit of the insertion of the sheets of covering metal. The strips may be placed in any position along the ship or vessel, &c., that may suit the width of the iron plates used in the structure. By means of this arrangement the sheets of metal are confined at the top and bottom in the grooves of the strips, and are fastened to the iron plates by rivets or screws between the strips when required.—Patent completed.

2414 J. L. NORTON and G. HAWKSLEY. *Improvements in apparatus and means for burning combustible liquids, vapours, and gases to obtain heat and light therefrom.* Dated August 22, 1867.

Here the patentees produce a suitable jet by forcing the liquid by a heavy pressure between two surfaces which are exceedingly close together, but which can separate or be separated to discharge any impurity from between them, and to regulate the flame they prefer that these surfaces should be held together by a spring, and that the liquid should be compelled to force its way between them, overcoming the spring. The orifice which the patentees use is formed by a conical valve and valve seat of hardened steel, and a spring adjustable by a screw holds the valve against the seat until it is overpowered by the liquid striving to lift the valve and escape. When the pressure of the liquid and the tension of the spring are suitably adjusted, the required smoke-like jet is readily adjusted; it may be ignited, and, if desired, directed into a furnace, or against any article it is required to heat.—Patent completed.

2415 F. ZIFFER and W. GOODBRAND. *Improvements in the method of warming carriages employed in the conveyance of passengers on railways.* Dated August 23, 1867.

This invention consists in effecting the warming by heaters in the form of cases, coils, tubes, or chambers of metal, or other suitable material, which are placed in the interior of the carriages in any convenient position, or in a chamber or in chambers in communication therewith, the cases, coils, or tubes being heated by steam conveyed from the locomotive and distributed to the heaters in a special manner.—Patent abandoned.

2416 D. WHITTAKER. *Improvements in healds or heddles used in looms for weaving.* Dated August 23, 1867.

This invention relates to those descriptions of healds or heddles in which metal wires having eyes are substituted for the ordinary heald cords and eyes, and consists in attaching loose eyes to metal wires, and in the modes of bending or shaping the wires so that this object can be attained. In one mode the inventor forms two loops at the ends of two pieces of wire, and links two eyes to the loops.—Patent abandoned.

2417 H. A. BONNEVILLE. *Self-acting cooking apparatus.* (A communication.) Dated August 23, 1867.

The patentee claims the use of apparatus consisting of a cooking vessel in which food or other substance is boiled or heated for a short time on a fire, or heated by other means, and a heat retainer in which the said vessel is afterwards enclosed, and in which the process of cooking or coction is completed, as described.—Patent completed.

2418 D. TAYLOR. *Improvements in the means of stopping or closing bottles and other vessels of capacity.* Dated August 23, 1867.

Here a cap of metal, &c., is provided to close the bottle, &c., at the neck, and this cap is filled, plugged, or fitted internally with cork, &c., made by preference on its lower surface with a part of its material projecting slightly downwards, and concentric with the circumference: slots, nicks, notches, or small openings are cut in the cap at the lower edge thereof, and studs, projections, ribs or nibs are formed on the outside of the neck of the bottle, &c. When the bottle, &c., is to be closed, the cap is placed on the neck, so that these openings come over these projections, and the cap is turned partially round on the neck, so as to bring the openings away from the projections, the elasticity of the cork or plug allowing a passage for the projections between it and the inner side of the cap. The cork, plug, or fitting enters the mouth of the bottle, &c., and a tight closure is effected.—Patent abandoned.

2419 W. S. ASHTON. *Certain improvements in metallic packing to be employed for the glands and stuffing-boxes of valves or cylinders used for steam or liquid.* Dated August 23 1867.

This invention consists in the employment of a novel arrangement and application of metallic spring packing within the "gland" or stuffing box, such spring packing being constructed to embrace the sliding rod in such a manner as to exert lateral pressure on the rod or spindle, which pressure may be adjusted so as to prevent steam or water escaping through the gland or stuffing box.—Patent abandoned.

2420 W. R. LAKE. *Improvements in the manufacture of iron and steel, and in apparatus employed in the said manufacture.* (A communication.) Dated August 23, 1867.

This invention consists in decarbonizing molten iron, or otherwise purifying it, thereby converting it into steel or malleable iron, or otherwise improving its quality, by the forcible dispersion of a stream of the melted metal into globules, particles, or atoms by a jet or jets of steam, air, or a mixture of the two, or any other gaseous element or elements adapted by their affinities for the purpose, within a vessel within which each globule, atom, or particle of the melted metal is brought into free and immediate contact with the gaseous element or elements within the vessel, whereby the elimination of the impurities which it may contain is effected.—Patent completed.

2421 E. A. DANA. *Improvements in the construction of concussion fuzes for the explosion of projectiles.* Dated August 23, 1867.

The nature of this invention consists, first, in suspending a striker or friction match carrier (longitudinally) in the friction chamber of the fuse, so that if the shell in which the fuse is placed strikes head on obliquely, or even sideways, the said match carrier shell, by its own momentum, frees itself and ignites the composition, and thus explodes the shell. Second, in the general combination and arrangement of the friction match carrier, the match chamber, and the friction match mixtures. Third, in the peculiar means adopted to prevent the carrier being liberated by any other force than that of the concussion of the shell when it strikes a solid object, and to ensure its being liberated by that force, and so explode the shell. —Patent completed.

2422 J. VARLEY. *Improvements in apparatus for raising, supplying, and measuring water to steam boilers, part of which invention is also applicable to measuring water for other purposes.* Dated August 23, 1867.

In order to supply water to steam boilers the patentee erects a closed cistern of a given capacity in a convenient position above the boiler. At the bottom of this cistern, and in connection with it, is another vessel of comparatively small capacity; this vessel is carried to a trunnion on which it is able to rock, and through which water passes from one vessel to the other, and in order that the water may flow freely from one vessel to the other a small pipe is led from the top of the rocking vessel to the top of the cistern. When the rocking vessel is empty, it is held up by a counterbalance weight, but when the vessel is full, or nearly so the weight is overbalanced and the vessel descends. Above the cistern is a small case or box, from the bottom of which a water supply pipe passes into the cistern. The top of the case or box is also connected by a pipe with the top of the cistern, and within the cistern each of these pipes is fitted with a valve. A steam pipe from the boiler is connected to the upper part of the cistern, and the end of this pipe within the cistern is also fitted with a valve. These three valves are all worked by the rocking vessel above mentioned, so that when the rocking vessel is in its highest position, the valves on the water supply pipe, and on the pipe which connects the top of the case or box with the top of the cistern, are open, whilst the valve on the steam pipe is closed; but when the rocking vessel descends, the valve on the steam pipe is opened, whilst the other valves are closed. There is also a valve at the bottom of the cistern on a pipe leading to the boiler, and dipping beneath the water in it. This valve is counterbalanced so that it requires to open it the weight of a column of water somewhat longer than the distance between the water line in the cistern when full and the high-water line in the boiler. —Patent completed.

2423 G. ALLIBON and E. WILSON. *Improvements in apparatus or gearing for steering ships.* Dated August 24, 1867.

This invention is not described apart from the drawings —Patent completed.

2424 J. and J. CASH. *An improvement in the manufacture of towels.* Dated August 24, 1867.

The object of this invention is to manufacture a good and durable friction towel. For this purpose the patentees take round cord and knit it or form it into loops by hand or machinery so as to constitute a complete towel, a selvage being formed all round. The cord must be sufficiently thick to give to the towels made therefrom the necessary roughness to enable them to be used as friction towels.—Patent completed.

2427 J. HANSON. *Improvements in agricultural apparatus for spacing and digging roots.* Dated August 24, 1867.

This invention relates to an apparatus patented July 30, 1865 (No. 1732), for digging potatoes, which may be briefly described as consisting of a light frame mounted on a pair of spiked wheels, the axle of which drives a horizontal shaft disposed longitudinally at right angles to the axle, such longitudinal shaft projecting at the back of the frame, and having on its projecting end a series of forks. When the machine is drawn by a horse or horses along a drill of potatoes, the forks rotate across the drill, and throw out the potatoes. The present invention consists in providing for driving the longitudinal shaft at either of two different speeds, and in arranging or adapting the machine for spacing turnips or other roots by removing the potato digging forks and plough piece used beneath those forks, and by fixing on the end of the longitudinal shaft a series of holes, and attaching to the frame a pair of coulters, one on each side.—Patent completed.

PROVISIONAL PROTECTIONS.

Dated January 8, 1868.

68 L. Simon, Hutchinson-street, Wilford-road, Nottinghamshire. A new mode of laying metal leaves on printed surfaces, and the apparatus connected therewith. (A communication.)

Dated January 25, 1868.

259 J. Mason, Sunderland, coal merchant. An improved composition to be used as fuel for household purposes, and the method of preparing or manufacturing the same.

Digitized by Google

Dated February 7, 1868.

418 A. B. Ibbotson, Sheffield. Improved steel spring railway fastenings. (A communication.)

Dated February 8, 1868.

440 N. C. Szerelmey, Belgrave-road, Pimlico. Improvements in rendering paper fabrics and other articles waterproof.

Dated February 11, 1868.

462 H. T. Humphreys, Westbourne Park-road, Middlesex. A new process for the decarbonization of molten iron for its conversion into steel, which process is also applicable for the decarbonization of other substances.

Dated February 12, 1868.

474 J. Thornton, Polygon, St. Pancras, cabinet maker, and F. W. Voss, Compton-street, Brunswick-square, engineer. Improvements in portable weighing apparatus.

Dated February 18, 1868.

538 A. M. Keighley, Beeston, Nottinghamshire, station master. Improvements in the method of, and means or apparatus for, signalling from one part of a railway train to another.

Dated February 19, 1868.

548 E. W. Young, New-street, Spring-gardens, Middlesex, civil engineer. Improvements in the construction of bridges.

561 M. Henry, Fleet-street, City. Improvements in the manufacture of nails, and in machinery or apparatus employed in the said manufacture. (A communication.)

Dated February 20, 1868.

564 J. M. Kilner, Chaplain of Chester Castle. Improvements in bedsteads or sleeping accommodation, principally intended for military purposes.

Dated February 21, 1868.

579 C. Cochrane, Woodside Iron Works, near Dudley, Worcestershire. Improvements in blast furnaces.

Dated February 24, 1868.

606 A. Stenger, Gresham-street, City, merchant. Improvements in umbrellas and parasols.

608 J. S. Gisborne, Liverpool, electrical engineer. An improved mode of, and means or apparatus for, indicating a ship's course, and preventing collisions at sea.

610 J. Fordred, Blackheath, Kent, chemist, and F. Lambe and A. C. Sterry, Rotherhithe New-road, Surrey, paraffin refiners. Improvements in the treatment of paraffin.

Dated February 25, 1868.

619 F. Le Roy, Commercial-road, manufacturer. An improved non-conducting composition for preventing the radiation or transmission of heat or cold, and an improved method of applying the same.

620 J. Elce, Manchester, machine maker. Improvements in lubricating the spindles of machines for spinning and doubling.

622 E. Hutchinson, Darlington, Durham, iron manufacturer. Improvements in the construction of multiple drilling machines.

624 G. W. R. Pigott, Halifax. Improvements in coated or covered wire.

626 J. J. and E. Harrison, Manchester, engineers. Certain improvements in the healds of looms for weaving.

627 J. C. Davies and E. Zahn, Kingsland-road, City, manufacturers. Improvements in muffs.

631 O. Ollivier, Panton-street, Haymarket. Improved apparatus, and means or method for, exhibiting advertisements and affording publicity thereto.

632 J. L. Jaquet, Vincent-square, Pimlico, sculptor. Improvements in heels for boots and shoes. (A communication.)

634 G. T. Bousfield, Loughborough Park, Brixton, Surrey. Improvements in apparatus for raising and forcing water, and for feeding steam boilers. (A communication.)

638 R. Ramsey, Upsal Pit, near Eston, Yorkshire, engine brakesman, and J. Cooke, Darlington, Durham, mining engineer. Improvements in signal indicators, applicable to mining and other purposes.

Dated February 26, 1868.

642 T. Hill, Merrylee, Cathcart, Renfrew. Improvements in bearings for axles and shafts. (A communication.)

643 R. Laidlaw and J. Thomson, Glasgow, engineers. Improvements in apparatus for exhausting gas for blowing air, for pumping or forcing liquids, and for measuring liquids.

646 J. Perrett, Eagle House, Herne Hill, Dulwich. Improvements in bottles and apparatus for feeding infants.

648 F. Lambe and A. C. Sterry, Rotherhite New-road, Surrey, paraffin refiners, and J. Fordred, Blackheath, Kent, chemist. Improvements in purifying hydrocarbon oils.

650 W. E. Newton, Chancery-lane. A new and improved washing machine. (A communication.)

652 R. and J. W. Gaunt, Springfield Mill, Farsley, Yorkshire. Improvements in spinning and twisting machinery.

Dated February 27, 1868.

655 J. R. Cooper, Birmingham, gun manufacturer. An improvement or improvements in breech-loading firearms.

657 T. Blocksage, Dukinfield, Chester, brick manufacturer. Certain improvements in the construction of boilers or steam generators.

659 R. E. Green, Church, near Accrington, Lancashire. Improvements in the preparation of cotton yarns or fabrics intended to be dyed with madder or a preparation of madder.

660 L. Boyce, Manchester, Venetian blind manufacturer. An improved mode of raising and lowering Venetian blinds.

661 J. B. Whiteley, Lockwood, near Huddersfield, Yorkshire. Improvements in machinery for stretching and drying or finishing woven fabrics.

662 W. Weldon, Park Villa, West Hill, Highgate. Improvements in the regeneration from chlorine residues of oxides of manganese, suitable for use again in the manufacture of chlorine, and capable of being applied also to other purposes.

663 J. Adams, turner, and H. Barrett, soda water manufacturer, St. Helier, Jersey. An improved stopper for bottles.

664 W. E. Newton, Chancery-lane. Improvements in the construction or building of boats or vessels. (A communication.)

667 J. H. Bass, Featherstone-street, City, machine cork manufacturer. Improvements in double cans or vessels to contain liquids or substances which it is desired to protect from the influence of external temperature.

668 W. M. Bullivant, Fenchurch-street, City, wire rope manufacturer. An improved composition for preventing the fouling of iron and other ships' bottoms, and for preserving metal and other surfaces generally.

669 G. Eldridge and W. C. Loe, Grange-road, Dalston. Improvements in the means of closing or stoppering bottles and vessels for containing aerated and other liquids or fluids.

Dated February 28, 1868.

671 J. Christie, Newcastle-upon-Tyne, stationer. An improved lithographic printing machine, by means of an endless tympan and self-acting gripping scraper, to be worked by hand, steam, or other power.

672 R. Mills, Bury, Lancashire, machinist. Improvements in machines for washing, wringing, and mangling textile fabrics.

675 A. S. Stocker, Artillery-street, Horsleydown, Surrey. Improvements in machinery or apparatus for the manufacture of caps or covers applicable to bottles and other vessels, and in the construction of such or other caps or covers.

676 R. Howard, Southampton, corn factor. Improvements applicable to taps and cocks for various useful purposes.

677 C. E. Brooman, Fleet-street, City, patent agent. Improvements in the manufacture of moulds for moulding glass or like material. (A communication.)

678 J. Leacock, Castlewellan, Downshire, Ireland. Improvements in paving for streets, roads, and ways.

679 J. Robinson, Greenfield, Yorkshire. Improvements in cleaning the surfaces of feed-water heating apparatus employed in boilers for generating steam, and in the apparatus connected therewith.

681 G. Thomas, Oldham, Lancashire, mechanic. Certain improvements in sewing machines.

682 T. Warren, Glasgow, glass manufacturer. Improvements in glass furnaces.

683 J. F. Low, Monifieth, Forfar, machine maker. Improvements in apparatus for preparing jute and similar fibrous materials.

684 T. Trotman, High-street, Camden Town, carriage builder. Improvements in the construction of doubling-up or folding carriages and chairs.

685 W. E. Newton, Chancery-lane. Improved apparatus for drying and finishing felted goods and fabrics. (A communication.)

686 C. Sanderson, Worksop, Nottinghamshire, steel manufacturer. Improvements in the manufacture of iron and steel.

687 T. S. Whilock, Aston, Warwickshire, ale and porter merchant, and H. Harford, Birmingham, carpenter. Improvements in fastenings for window sashes.

688 J. Gjers, Middlesborough, Yorkshire, engineer. Improvements in the manufacture of cast steel and homogeneous iron, and in furnaces applicable thereto.

Dated February 29, 1868.

689 C. Cochrane, Woodside Iron Works, near Dudley, Worcestershire. A new or improved appliance for hot blast water tuyeres.

695 G. Lindsley, Swindon, Wilts. Improvements in obtaining and applying motive power for propelling carriages and for other purposes, and in apparatus employed therein.

697 A. H. Hill, Inner Temple, City, Barrister-at-Law. Improvements in luggage labels or pads.

699 J. L. Norton, Belle Sauvage-yard, Ludgate-hill, City. Improvements in sinking or forming wells, and in apparatus to be used for this and similar purposes.

701 B. Solomons, Albermarle-street, Piccadilly, optician. Improvements in telescopes.

Dated March 2, 1868.

703 W. J. Armstrong and C. Browne, Burton-terrace, Brixton, Surrey, master mariners. Improvements in anchors.

707 J. Rawsthorn, Preston, Lancashire, corn miller. Improvements in machinery for dressing millstones.

711 S. Sharrock, Liverpool, engineer. Improvements in the construction of piles.

Dated March 3, 1867.

713 A. A. Usher, Compton-road, Canonbury. Improvements in respirators.

715 C. Cochrane, Woodside Iron Works, near Dudley, Worcestershire. Improvements in valves or dampers for pipes, passages, or flues serving to conduct gases at high temperatures.

PATENT APPLIED FOR WITH COMPLETE SPECIFICATIONS.

Dated March 9, 1868.

818 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in the treatment of fibrous materials for the manufacture of various articles, and in the means for rendering the same fire and waterproof. (A communication.)

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the "London Gazette," March 17, 1868.

3061 C. and J. Jobson. Screw propellers.
3089 J. J. Hicks. Backs and handles for brushes.
3094 C. Riley. Tubular boilers.
3096 J. Fraser and G. Duncan. Counter-check books.
3098 R. Ackroyd and G. Hodgson. Looms for weaving.
3108 W. R. Lake. Artificial compound to be used as a substitute for india-rubber. (A communication.)
3131 R. Newton. Fuel-feeding apparatus for steam boilers.
3139 T. R. Bardsley and W. Blackshaw. Apparatus for smoke-consuming in steam boiler and other furnaces.
3143 C. H. Bright. Tramways for streets.
3147 I. Hewitt. Machine for forming labels.
3157 G. W. R. Pigott. Apparatus for covering wire with metal.
3170 S. Simon. Manufacturing aprons. (A communication.)
3173 C. Bedells. Manufacturing elastic fabrics.
3184 T. J. Leonard. Machinery for rolling iron into bars.
3186 W. R. Lake. Cylinder printing machines. (A communication.)
3187 W. R. Lake. Cartridges for breech-loading firearms. (A communication.)
3189 W. R. Lake. Breech-loading firearms. (A communication.)
3194 J. C. Bayley and D. Campbell. Fire-lighters.
3196 H. A. Bonneville. Machines for moulding bricks. (A communication.)
3206 J. Carter and T. Chalmers. Fittings of windows and doors.
3214 W. R. Lake. Breech-loading firearms. (A communication.)
3215 U. P. Wurflein. Instruments for joining blind cords.
3216 R. Adams. Breech-loading firearms.
3217 E. Madge. Apparatus for the reduction of sulphate of iron crystals. (Partly a communication.)
3218 E. Madge. Apparatus for feeding metal plates to rolls.
3221 R. F. Fairlie. Locomotive engines.
3224 G. Kent. Kneading machines. (A communication.)
3226 W. H. Richardson. Manufacture of iron and steel.
3228 L. A. Wainman. Apparatus for raising water.
3229 A. M. Clark. Apparatus for applying bronze powders on paper. (A communication.)
3230 J. P. L. Heckmans and F. J. Nunney. Washing machines.
2231 W. R. Lake. Steering apparatus. (A communication.)
3233 R. G. Harcourt. Manufacture of fire-lighting material.
3238 A. Airian. Hydraulic clocks.
3245 R. Howson. Gas furnaces.
3251 R. Garbett. Constructing parts of certain games.
3258 W. R. Lake. Covering buckles. (A communication.)
3262 R. Husband. Manufacture of hats.
3263 E. Lord. Machinery for opening cotton.
3279 A. Barclay. Motive-power engines.
3282 W. H. Richardson. Manufacture of iron and steel.
3312 G. Welch. Mode of killing whales.
3505 C. Conner. Umbrellas.
3616 J. Kerr. Breech-loading firearms.
57 H. Smyth. Umbrellas.
138 J. Kidd. Obtaining artificial light.
389 S. G. Taylor. Lubricating the spindles of machines for spinning.
430 J. Howard and E. T. Bousfield. Construction of steam boilers.
575 R. Fennelly and P. Kenny. Apparatus for singeing off the hairs on pigs.
579 C. Cochrane. Blast furnaces.
610 J. Fordred, F. Lambe, and A. C. Sterry. Treating paraffin.
637 A. M. Birchall. Manufacture of twist tobacco.
648 F. Lambe, A. C. Sterry, and J. Fordred. Purifying hydrocarbon oils.
818 W. R. Lake. Treating fibrous materials. (A communication.)

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list, who have given notice of their intention to proceed, within twenty-one days from the date of the "Gazette" in which the notice appears, by leaving at the Commissioners' office, particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed March 13, 1868.

2599 W. G. Brownson
2606 G. Pickin
2613 W. Brailsford and J. Gadsby
2610 W. J. Cunningham

THE

MECHANICS' MAGAZINE.

LONDON: FRIDAY, MARCH 27, 1868.

NATIONAL INTERCOMMUNICATION.

EVERY nation, even those existing in a state of semi-barbarism, may be said at the present time to be actively engaged in the arduous task of improving their means of intercommunication with adjacent countries, as well as distant lands. To relieve the physical features of a country from their native isolation and primeval ruggedness, and to place the interior, as well as the coast, *en rapport* with its neighbours, is one of the first efforts that awaits the labours of the Government. A complete system of main routes must be opened up, whether the means adopted be that of common roads or the more modern one of steam locomotion. The misguided policy so frequently and fruitlessly adopted of making short roads literally leading nowhere, and having no terminus of any importance at either extremity, should be discarded. A main arterial route of intercommunication should not consist of a number of disjointed fragments, of a variety of short lengths, connected with one another as time and local circumstances presented either the opportunity or the necessity of so doing. It may be impossible to construct without interruption, without perhaps a prolonged delay, the whole of an important route 200 or 300 miles in extent, but still the principle should be adhered to of laying out the main arteries of traffic in a manner so that they should connect the principal towns and local foci by the most direct course. As a rule, deviations, unless very slight, should not be introduced when the purpose in view is to include a small town or village lying contiguous to the line of route. Instead of deviating the main line, its course should be kept as nearly uniform as the features of the district will allow, and small branches should be constructed to all places situated right or left that may need them. Our own main lines of railways afford an example of what may be termed piecemeal construction. There are but one or two—the Great Western from London to Bristol is a case in point—which were originally laid out to their full extent, but the large majority are made up of short local lines, joined together as the necessity arose, and comprise a most imperfect and defective system. Hence the construction of future loop lines and new routes, which would have been altogether unnecessary had the guiding principle we have alluded to been adhered to in their original laying out. An admirable corroboration of our views is to be found in the older South-Eastern line to Dover. At first it was never intended to extend from London any farther than Reigate, but in 1863 the extension to Dover was commenced. A glance at the map is sufficient to show what a great bend occurs at the former place, constituting, in fact, a deviation at nearly right angles to the absolute course of the line. What has been the result of constructing between the two termini so protracted and indirect a route? In the first place, another company has made a rival line having a better selected course; and in the second, the South-Eastern itself has demonstrated the fallacy of its original plan of communication, by constructing a loop line over twenty miles in length, cutting off the angle made by the older line at Reigate.

It is undeniable that commercial prosperity and national wealth is a sheer impossibility with a people who have not reduced what our Gallic neighbours call *les ponts et chaussées* to a definite organization, and embodied the plan of intercommunication in all their municipal and local acts of jurisprudence. The Eastern nations, who from the almost exclusive use they make of horses, mules, and camels as beasts of burden, have less need of carriage roads than others, are at the present engaged in their construction, and also in that of railways. Probably, the interests of commerce are not the only spur to the lethargic orientals; it is a question of policy for them to imitate the example set them by their western brethren, and the administrative power possesses greater energy and vigour, in proportion as the confines of the State are more easily accessible from the central seat of the Government of the empire. There is very little doubt but that in new countries, not new in the sense of discovery or colonization, but in that of civilization, such as India, railways have been constructed, in many instances, where the immediate interests and welfare of the community would have been best consulted and advanced by the establishment of a good system of carriage roads. Greece is a new country in the sense understood, and it is satisfactory to observe that the first efforts of the Government have been directed towards the construction of several main lines of road traffic, and the ultimate completion of the whole system. The physical difficulties presented by the country are well known, but the pick of the navvy and the blast of the miner will speedily open up the pathless valleys and level the superincumbent precipices. About nineteen separate roads have been opened up or are in course of formation, comprising a total extent of nearly 300 miles, the greater portion of which runs through mountainous districts of exceeding beauty and sublimity. Some of the views through the gorges and ravines are described as perfectly magnificent. The chief portion of the work of these roads was performed by the inhabitants themselves, the Government supplying assistance only in the more arduous and expensive items of bridges, culverts, and viaducts. Greece has been liberally provided by Nature with mineral wealth, and in order to attain facilities for its exportation, several small lines of railway have been projected from the interior to the various ports along its shores. One of the most important and most needed is a line which, starting from the southermost point of the Peloponesus, and taking in as many towns as possible situated in the interior, would touch at Corinth, traverse nearly the entire isthmus, and finally debouch upon the Turkish frontiers, where a junction could be readily effected with the great lines of the Italian system. Another route, equally important as the one just described, should be laid out so as to connect the Peloponesus and the interior of Greece with the ports upon the Egean and Ionian Seas, and a third should connect the shores of the latter sea with Athens and the Piræus. Branches and feeders, either in the shape of carriage roads or small railways, could be added as the resources of the country permitted, and as the traffic and internal commerce afforded the funds. The total extent of this system of communication would not exceed, at a rough estimate, 500 miles, a distance comparatively insignificant when contrasted with the great American and Indian railways. The locomotive route from Calcutta to Delhi exceeds 1,100 miles in length, and crosses on its way rivers of considerable dimensions. The Jumna and the Saone, the latter of which is traversed by a bridge 3,000ft. in length, are not likely to find many rivals of similar magnitude in Greece. It is needless to remark that the land would cost nothing, and that there is abundance of timber in the country available for bridges and other works, which might, in the first instance, be constructed of that material, as it would be necessary, for obvious reasons, to keep the expenditure as low as possible.

THE "VALIANT" AND HER SCUPPER-HOLES.

THE "Valiant" is by no means the most useful vessel we possess for defensive purposes, seeing that her armour-plating is only 4½in. thick. She might, however, have answered very well for some purposes; for instance, armed with Major Palliser's converted 68-pounder rifled gun, she would have made a very good channel or harbour guardship. But what little efficiency she did possess is unquestionably being drilled out of her now, as she is having a number of scupper and scuttle-holes cut through her armour-plating and sides. The work, however, affords an opportunity for testing a new system of drilling, which appears to be very successful; so, we suppose, we must console ourselves therewith. The holes are being cut through the armour-plating by two methods, the old and the new. The old method consists in boring a number of holes close together round the scupper or scuttle-hole to be cut through the armour-plating, and afterwards cross cutting them and bevelling off the hole. Each hole under this system occupied about a week to complete; by the new method, however, it takes but nine hours to cut and finish a hole through the 4½-inch plating. In the latter case, a series of six cutters are set round a piece of shafting, the end of which, and the points of the cutters, being firmly pressed against the ship's side by temporary iron stays. To the shaft is attached a ratchet arrangement worked by three men, and by this apparatus the piece of iron is taken clean out of the armour-plate. The cutters can be set at any angle on the shafting by means of regulating screws, and they can also be fixed to cut a hole of any given diameter. By this ingenious arrangement any slope can be given to the sides of the scuttle, and the work can be finished off at one operation. So far, then, the "Valiant" has been of service in affording evidence of the practical value of this new system of piercing scuppers through armour-plating. But this is at the expense of the public purse and her own strength, for what will she be worth for defensive purposes with a maximum thickness of only 4½in. of plating, and that armour pierced throughout the length of the ship with a double row of holes for scuppers and scuttles just above the water line? It is more than a pity that all this time and money should be expended upon a vessel which could not originally boast very great defensive strength, and it is still worse that the only result of the expenditure will be to destroy what little strength she had. This ship of 800-horse power was completed by the Thames Ironworks Company more than three years since, and has never yet been in commission, save a few days, when the fleet was reviewed by the Queen and the Sultan. When she is ready to be placed in commission—which cannot be for some time yet—she will have cost a very large sum, and, with her perforated sides, will be of very little service. Her usefulness will have been confined to demonstrating the efficiency of a new boring tool. If an improved apparatus be brought out in time, we suggest it should be set to pierce another set of holes a little below the water line.

WHAT IS A METAL? WHAT IS A METALLOID?

M. NAQUET, Professor Agrégé à la Faculté de Médecine de Paris, has just published a species of physico-chemical work wherein he gives definitions of matter in general, and of the kinds of matter in particular, which surround us. We love a definition, clear, comprehensive, and precise; in fact, without such no conclusive reasoning can be carried on, and no discussion should be attempted. We can have no cause of complaint against M. Naquet's general definition

Digitized by Google

of matter on this head: we think it is perfect. We will give a sentence or two from his book which lead up to it. "If we cast our eyes on that which surrounds us, we are struck by the view of a multitude of objects, of an infinite diversity: all these objects, whatever they may be, have received the generic name of bodies. That which constitutes these bodies is called matter or substance. In a general manner, one may say that matter is all that which strikes the senses, and in a manner more scientific that matter is, all that which obeys the laws of gravitation." Here, then, is a definition, clear, comprehensive, and precise. Matter is that which obeys the law of gravity: or has weight. But it is here taken for granted that we have a clear and distinct idea of what we mean by gravity. It may be that it is taking a little too much for granted. Perhaps there needs another definition to make this definition perfectly intelligible; as, indeed, Newton's law of gravity needs another law of force in act and in effort to make it perfectly understandable. However, we will leave this for the present, and turn to definitions which are much less satisfactory. With the work at large we do not here purpose to meddle.

M. Naquet divides matter into two classes, which he designates metals and metalloids. He gives the properties of these two classes of bodies in two categories, as follow—

METALS.

I. There is no gaseous metal.
II. Metals possess metallic lustre.
III. Metals are good conductors of electricity and heat.
IV. Metals have a density relatively high.
V. Oxides of metals, on combining with water, produce bases—seldom acids.
VI. Metals are always electro-positive in compounds which they form on uniting with metalloids.

METALLOIDS.

I. Several metalloids are gaseous.
II. Metalloids have not the lustre called metallic.
III. Metalloids are bad conductors of heat and electricity.
IV. Metalloids have a density relatively low.
V. Oxides of metalloids, on combining with water, ordinarily produce acids—seldom bases.
VI. Metalloids are always electro-negative in compounds which they form on uniting with metals.

Now, what are we to make of these two lists of properties. No. 1 of metallic properties says that there is no gaseous metal. If M. Naquet had added, at the freezing point of water, it might have been true, but is not true as it stands. Are not mercury, magnesium, sodium, potassium, arsenic, zinc, &c., well known in a state of vapour or gas. Faraday has shown that gas is simply a solid in a state of vapour. It is simply a question of heat. No. 2 says that metals possess metallic lustre; of course, what other lustre can they possess. No. 3 is certainly true of metals, less or more; but still expresses no definitive property. No. 4 says that metals have a density relatively high. But some metals have a density relatively low also; for example, magnesium, and many others, are much less dense than sulphur, carbon, &c. No. 5 describes a property that is not common to all metals. No. 6 is the only property which is stated to be universal to all metals, except No. 1, which certainly is not universally true in the unrestricted form in which it stands. Metals are always electro-positive in compounds which they form with metalloids. But, then, what is a metalloid. The descriptions or definitions of its properties are as undefined as those of a metal; perhaps more so, for they are principally negative. Some metalloids are said to be gaseous. That of course is not a general property of a metalloid, and will not serve as a distinguishing mark. Metalloids are said not to have metallic lustre. Of course, if they have lustre, it will be metalloidal. Nos. 4, 5, and 6 are simply the opposites of the properties assigned to metals under the same numbers. Now, what is a metal, and what a metalloid after these definitions of properties.

The only thing like a definition of a metal is that it is electro-positive in the compounds which it forms with metalloids, and that of course the metalloid is negative. But if we take this as a precise general definition, how are we to apply it? We think in this way; that when we find a compound we must call the positive constituent of that compound a metal and the negative constituent a metalloid. Then, in the compound water, hydrogen is a metal and oxygen a metalloid; but the first article in the category of metallic properties says that no metal is gaseous, much less a permanent gas at all known temperatures. Hydrogen may be a metal in the state of gas—probably is—but it does not agree with M. Naquet's definitions. Natural objects refuse to be catalogued and put in exact and precise categories of order, genus, species, &c. Nevertheless, these artificial means of assisting the mind to grasp this infinity of natural objects have been and will still be of incalculable use; but it must not be pushed beyond its legitimate use. We must class and define; but let our definitions be clear, and let them not contradict each other. We fear that as yet our knowledge is such that we shall have to be content to place physical objects under more classes than two. It may be that there is but one substance, and that the varieties of matter are but the varieties of form. Nay, we think it is even more than probable.

RAILWAYS AND THEIR MANAGEMENT.

WE last week gave an abstract of a remarkable paper which was read before the Society of Arts by Mr. R. F. Fairlie, C.E., on the subject heading this article. A copy of Mr. Fairlie's paper, and the discussion upon it, is now before us, and from the grave nature of the questions therein, and the originality of the facts set forth, we are induced to bring it again before our readers. It ranks, in our opinion, among the most interesting and practically suggestive papers that have been produced before any society. The importance of the subject will be at once admitted, when it is remembered that considerably over £500,000,000 sterling is involved in its consideration, a very large proportion of which is at this moment wholly unproductive, if not entirely lost, and we hail with satisfaction the suggestion of any measures that shall remedy the present unfortunate condition of our railways. Mr. Fairlie does not stop to mourn over the past, but earnestly sets to work to change the aspect of things in the future. He says, "It would be of no avail to refer to the waste of past expenditure in construction, except to say that the teachings of the past are the only safe guides to the policy of the future"—which means we cannot undo what has been done, but should strive to make the most of that we have by careful, economical, and yet efficient management, and so bring back what, at this moment, is apparently lost to the unfortunate shareholders. We should then make our railway property what—from the enormity of our traffic it ought assuredly to be—the best and safest class of investment. Mr. Fairlie very properly deprecates great waste of the shareholders' money in building palatial stations, and considers there has been a greater desire on the part of our engineers to create monuments to their own fame than properties useful and beneficial to their employers. We write and talk much about the law of master and servant, and are very wroth when we hear of a few tailors or cabmen combining to protect themselves from the encroachments of their masters, but, we ask, was ever combination more complete, more perfect, or were men ever more masters of the situation, than the engineers of this country. Rattening is well understood in Sheffield, but we question whether even they there understand the refined cruelty inflicted on the widows and orphans, who find their little all, which they had invested on the faith of some great name, hopelessly gone, —and gone where? Into extravagancies of all kinds, to suit the fancies of those whose personal benefits are in proportion to the monsters of their creation.

The Marquis Clanricarde, in his reply to the discussions on Mr. Fairlie's paper, speaking of the enormous capital invested and the facility of its extension, made use of the following striking words, which are remarkably corroborative of what we have just advanced. Said the Marquis:—"The consequence is that an immense quantity of money has been thrown away, which might just as well have been spent in building a pyramid in a desert." We who pride ourselves on our intelligence, and in our commercial probity and knowledge, are at this moment the laughing stock of the whole world, because this grand intelligence has involved us in a loss of nearly £125,000,000 which might readily have been avoided. We have need, forsooth, to alter our policy in the future if we intend to prevent the whole railway system from becoming hopelessly bankrupt. However strange it may appear, our railway managers are determined not to be behindhand in wasteful extravagance. Only imagine a company like the London and Brighton Railway earning, it is said, as much as £3 per train per mile, yet the average for each train mile is under 4s. 10d. Surely this requires no comment of ours: it speaks for itself; we can only account for it by the dispatch of as many trains earning below 4s. 10d. as above that amount to bring the whole to this average. The fact is that many trains must actually run at a heavy loss on the plea of accommodation to the public, but this is not so. And here we cannot do better than quote Mr. Fairlie's own words. He says, "The best test of this is the patronage bestowed on particular trains, and the neglect of others which consequently do not pay." Nothing can be more clear than that if the trains which now earn nothing were a convenience, the public would avail themselves of them, and the natural course of things would be that each train would pay.

This despatching of unremunerative trains accounts for the great disproportion of the paying to the unpaying load, as shown by Mr. Fairlie, and corroborated in a letter of Mr. Samuel, which appeared in the money article of the "Times" on Monday last, although it will not account for the enormous disproportion of paying to unpaying loads on the Metropolitan Railway, which is said to be only one ton to every thirty tons. Then, again, there is the persistency with which our locomotive engineers continue to run those useless and expensive appendages to the locomotive engine called tenders, which weigh more than eight tons each. The average paying load of our passenger trains has long surprised us, more especially as it has been over and over again shown that the supplies which the tender carries, if placed on the engine, can be made available for increasing its power; we do not mean in the ordinary destructive form of tank engine, but the weight distributed over a large number of wheels, yet having a small wheel base, as in the bogie engine. The same reasoning holds good with the merchandize trains. In this case the tender weight would equal two waggons carrying five tons each, thus giving a nett paying load of ten tons of goods for every train mile run in lieu of tender. These ten tons at one penny per ton per mile would give tenpence per mile, or about one-third more than the present amount derived from mer-

Digitized by Google

chandize traffic for division amongst those shareholders who may be so fortunate as to get anything like two shillings and sixpence per train per mile from this source.

In speaking of the Metropolitan Railway, Mr. Fairlie paid a well-merited compliment to its designers and constructors, but he considered the management altogether bad, so bad that, if persisted in, a very few years would suffice to reduce it to a very low condition indeed. The expense of maintaining and working this line is something enormous, and this, we believe, could be very much improved, not only to the great advantage of the company, but to the travelling public. In explanation of this, Mr. Fairlie says, "The carriages have very long wheel bases, consequently they offer great resistance to the tractive force of the engine, besides being very injurious to the rails rounding the curves. The engines have thirty-two tons on four wheels, or sixteen tons per pair. We have only to imagine this enormous weight ploughing along at thirty miles an hour, to form some idea of the destructive effect, not only to the rails, but to the substructure and the machines, the effect being destructive alike to all. No wonder that the line has, as it is stated, been relaid in many places three times with steel rails since it opened five years ago. Not content with this rate of destruction to road and stock, the Metropolitan Company are now receiving, or about to receive, locomotive engines of a still more destructive character to work the St. John's-wood branch, weighing forty-five tons on six wheels, with a wheel base of 14ft. The only approach to a saving feature in the 42-ton engines—viz., carrying the leading end of the engine on a bissel truck with four wheels—is in these new engines omitted. The bissel arrangement does, to some extent, reduce the enormous friction of the engines on rounding the curves, notwithstanding which the grating and grinding noise of the wheels can be heard at a considerable distance. The spirit of rivalry between armour-plates and guns is reproduced in steel rails and locomotive engines, with this difference, that the armour-plates can be made to withstand the power of the heaviest guns, whilst steel rails cannot withstand the battering of these 45-ton steam-hammer locomotive engines." To sum up the matter is only to repeat what we have already said several times of late, that unless a hearty and thoroughgoing reform—as pointed out by Mr. Fairlie—both in construction and management be introduced in our railway system, we can never hope for improved dividends, much less for a recovery of any portion of the vast sum of money now apparently, but, we trust, not irretrievably, lost.

THE HARVEY TORPEDO.

SOME interesting and highly successful experiments have recently been made with the torpedo which has been invented and perfected by Captain John Harvey, R.N., and of which full particulars will be found at page 189 of the MECHANICS' MAGAZINE for March 29, 1867. The experiments in question came off last Wednesday week, in the presence of two members of the Floating Obstruction Committee and a number of naval and military officers. On the day in question, the "Lightning" and the "Asp" proceeded out of Milford Haven to test the practicability of Captain Harvey's diverging torpedoes for the destruction of vessels at sea. The shells diverged from two to three points on each quarter, and one was brought into collision with the "Asp." The levers immediately acted, proving that had it been a live torpedo the "Asp" would soon have disappeared from the face of the water, as she would have experienced the full force of the explosion of 100lb. of Horsley's powder. The application of the safety key was then tested, and the results proved equally satisfactory. This concluded the experiments made by the Government. The inventor—Captain Harvey—had provided a small smack inside of the harbour for the purpose of testing the working of the exploding apparatus. A small "right astern" shell, containing 19lb. 6oz. of Horsley's powder, was towed into collision with the smack, but owing to her small height above water, and owing also to the "Lightning" having to round her stern close, on account of shallow water, the tow line slipped over the counter, and the shell, instead of exploding under the bottom, as intended, jumped on the deck and there exploded. It, however, shattered everything on board to atoms, leaving the hull of the smack a charred mass, with her upper works clean gone, and her beams fractured, proving to any unprejudiced mind the extraordinary power of Horsley's powder. There can be no question that had the torpedo been towed into collision with the bottom of the smack she would have been totally destroyed, if not lifted out of the water. Our readers are so well aware of the specialities and general excellence of Captain Harvey's torpedo that we are content to let the results of these experiments speak for themselves; their success places them beyond comment. We may, however, point out that this invention can be used with as much success in a gale of wind as in a calm, which is more than can be said of any torpedo boat. Another great advantage is that no battery nor other complicated exploding apparatus is required. We congratulate Captain Harvey on having succeeded in drawing the attention of the Government to his highly practical apparatus, and we hope it is the first step to a series of trials, preparatory to its adoption for defensive purposes.

BREECH-LOADING RIFLES.

OUR readers will doubtless remember that on the 22nd of October, 1866, a War Office advertisement appeared, offering three prizes for breech-loading rifles and ammunition. These were a prize of £1,000 for the arm which, on combination of all the qualities, should be considered by the committee to be the best submitted; a second reward of £600 for the arm which, while attaining a satisfactory degree of excellence in other particulars, should be selected for merit in respect to its breech mechanism; and a third reward of £400 for the best cartridge. The first report of the sub-committee has just been published; it only deals with the first stage of the inquiry, that is, with the selection of the prize arm. It appears that none of the arms submitted satisfied the whole of the conditions. The committee selected nine for trial, viz., the Albini and Braendlin, the Remington, the Fosbery, the Burton (two systems), the Peabody, the Martini, the Joslyn, and the Henry rifles. Every one of the competing arms sooner or later fell short in some degree of the minimum of excellence prescribed. The committee have not awarded their £1,000 prize at all, but have given the £600 prize (for breech mechanism) to Mr. Henry's gun. This arm is a smallbore (·455-in.) rifle, very similar in the arrangement of its breech action to Sharp's carbine. The breech is closed by a sliding vertical block, which is depressed for the admission of the cartridge by a lever underneath the trigger-guard. The striker passes diagonally downwards through the breech-block, and is struck by a hammer. The Boxer cartridge is employed with the gun. This arm won the £100 prize of the National Rifle Association in 1865, and acquitted itself very creditably last year at Wimbledon. With regard to the cartridge prize we are glad to find that the trials of ammunition having been concluded, the committee by whom they were conducted have reported that the ammunition submitted by Mr. Daw, of Threadneedle-street, has so far fulfilled the prescribed conditions as to justify them in awarding the prize of £400 to that gentleman. Sir John Pakington has accordingly given directions for the payment of this sum to Mr. Daw.

THE PHOTOGRAPHIC SOCIETIES.

THERE are three photographic societies in the metropolis, namely, the London Society, the North London Photographic Society, and the South London Photographic Society. The result of this division among photographers is, that all three societies do little more than clear the expenses of their meetings for the reading of papers, and have no funds for the establishment of a laboratory for scientific investigation, or for the formation of a photographic museum. Hence photography, as a science, is not pushed on as it should be by its public representatives, research being left entirely to private individuals. The latter investigators, as a rule, make researches in photography only on casual occasions, when they have leisure from other pursuits; hence the papers read at the societies refer, for the most part, to modifications in photographic apparatus or processes, and the higher branches of the subject are neglected more than is creditable to the fraternity. One very strong reason why improvement should be attempted is that the three disunited societies now expend enough to raise a very creditable yearly fund for the promotion of scientific research, but this surplus is at present wasted, because the societies, being separated, have to provide three different places of meeting, and incur a constant outlay to pay the rent of the same: likewise to keep the rooms in order. One of the societies, also, will soon have a considerable balance in hand, because its secretary, who formerly received nearly all its funds in the shape of salary, has volunteered to act as honorary secretary for the future. The annual subscriptions to some of the societies are less than those paid by the members of the others, so that if the latter gentlemen only agreed to have their contributions slightly raised to reach the higher level, the result altogether would be to produce a considerable sum of money annually, to help to raise photography, both as a science and an art.

Although to every outside spectator the union here suggested seems nothing but a common sense and obviously unobjectionable arrangement, it is one unfortunately which seems little likely to be adopted in practice. One reason is that feuds and petty jealousies exist among a few of the members of the different bodies, though in each of the three societies are many who overlook such trivial matters, and long for union. Trade interests, also, are said to have something to do with the divisions in the camp, for which reason it really would be a very good rule to adopt, that no member commercially interested in photography should be eligible to become one of the council. As such a rule would prevent many clever men from occupying the position, it would be invidious and wrong for an amateur to move the above proposition of non-eligibility, but the difficulty might be overcome by two large manufacturers of photographic goods moving and seconding, for the good of the art science, the proposition which prevents them from taking office. There would afterwards be a greater prospect of peace and union among the members, because then one leading photographer or manufacturer would never have reason to suppose he was unfairly treated, because one or two of his competitors in business chanced to be in office on the council of the society.

In all stages of photographic history, from its earliest days, the question of the permanency of photographs has always been a great one, and nothing is more disappointing than the absence of accurate evidence respecting the durability of different classes of silver-printed pictures. Now, this would never have

Digitized by Google

been the case had one of the societies ever had the forethought to make the beginning of a museum, in the shape of a large glass case with lock and key, wherein the advocates of new processes should be compelled to place one specimen of their work, with minutely detailed particulars of the formulæ and manipulations. These pictures, being the property of the society, and exposed daily to strong daylight in the glass case, would not only form a most interesting historical record of the progress of photography, but the society would have ocular and authenticated evidence as to the durability of the different kinds of pictures. Yet, to this day, not one of the societies has adopted even such a simple and cheap plan as this. While such is the case, the expectation that a laboratory for scientific experiments will ever be established by the members of photographic societies, does indeed seem hopeless. Under these discouraging circumstances, with little hope of the council of one society favouring union with the council of another, coupled with a fresh general election of officers, we think the best practical thing to be done by those members of the three societies who desire union, is to ascertain their own numerical strength, and see whether they cannot fuse themselves into a stronger photographic association than any now in London. Above all things, care should be taken to avoid the representation of trade interests in the governing body of the society, this being a most fertile source of discord.

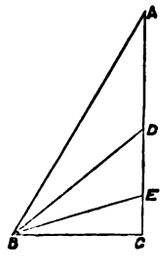
BOWSTRING GIRDERS.

IN the bowstring girder we have an arched iron rib, the horizontal thrust of which at the abutments or points of support is resisted by a tie-bar, the platform which carries the load being suspended by vertical pieces from the arched rib or bow. In order to determine the straining action exerted in such a form of girder, having a load uniformly distributed over the platform, let L denote the length in feet of platform, or span of bow, and w the load per foot of span; then w L = total load. Now, since the load is uniformly distributed, each of the points of support will bear one-half of this load or $\frac{w\,L}{2}$. There are thus two equal forces at each end of the bow acting vertically upwards, due to the resistance of the supports. The direction of the resultant of all the downward forces, or total load, is also vertical, and will pass through the crown of arch and middle of span. If we confine our attention to one-half of the girder we find that the result of the action of these forces is a "couple," the equal and opposite forces of which are $= \frac{w\,L}{2}$. The arm of this couple is $\frac{L}{4}$, because the resultant of the load on half the span acts through a point at a distance from end of girder, equal to one fourth of the span. The "moment," then, of this couple is $\frac{w\,L}{2} \times \frac{L}{4} = \frac{w\,L^2}{8}$, and the effect of its action is to cause depression at the crown of the arch. To resist this action an equal and opposite couple must be introduced by means of the tie-bar. This is effected by the resistance opposed by the tie-bar to the horizontal thrust of the bow at the points of support; this thrust is constant throughout the whole of the bow, and, therefore, we get for the forces of this new couple the tension on tie-bar and the equal and opposite horizontal thrust at crown of arch; the arm of this couple is the rise of the arch or vertical distance between the middle of platform and crown of arch. Let R denote the rise and T the thrust or tension, then T R = moment of couple and $T\,R = \frac{w\,L^2}{8}$

$$\therefore T = \frac{w\,L^2}{8\,R}.$$

Sufficient sectional areas must be allowed to resist the action of this stress. These areas are the same as those for the middle sections of the top and bottom members of a plate or lattice girder of the same depth and span, the formula being the same in both cases. In plate or lattice girders, however, the sectional areas decrease towards the points of support, whilst in the bowstring girder an increase should be made, the sectional area of tie-bar remaining constant; thus in its upper and lower members the bowstring girder must be much heavier than the plate or lattice girder.

The thrust throughout the bow in the direction of its curvature may be found at any point by constructing a diagram similar to that annexed, in which the vertical line



A C represents the half load $= \frac{w\,L}{2}$, and the horizontal line B C the tension on the tie-bar = horizontal thrust in bow $= \frac{w\,L^2}{8\,R}$; join A B, then the line A B will represent in magnitude and direction the thrust through the arch at the point of support. Take any point D in the bow and let the line D C represent the load acting upon the girder from the centre of span to that point, B C, as before, representing the tension on tie-bar, then B D represents the thrust at the point in question. To distribute the action of a rolling load, diagonal pieces are introduced between the vertical bars; these diagonals will act alternately as ties and struts. Comparing the weights of bowstring and lattice girders, we find that the former is the heavier. Theoretically speaking, the top and bottom members of a lattice girder will contain less than two-thirds of the material in the same members of a bow and string girder; and the greater quantity of material required for the diagonals of a lattice girder, as compared with that for the stiffening diagonals of the bowstring, will not make up the difference already mentioned. W. J. M.

NOTICES OF BOOKS.

THE constant improvements which are being made in mechanical engineering, and the changes that take place almost daily in matters of constructive detail, combine to render necessary the constant revision of any treatise specially devoted to the subject. Indeed, we may go further, and say that in a few years, at the most, such works now become comparatively antiquated, so rapidly do improvements succeed each other and lead to radical changes in practice. It is, therefore, with satisfaction that we announce the issue of another—the eighth—edition of Mr. Bourne's well-known treatise on the steam engine.* It is, however, but just to remark here that the present work does not fall entirely within the category of books that soon become antiquated, inasmuch as it deals largely with principles, as well as with practice. It treats of the steam engine in all its varied applications, and contains some sound theoretical investigations respecting the motive power of heat. The proportions of steam engines are given, with elaborate tables of the correct dimensions of every part. Then we also have a series of practical instructions for the manufacture and management of engines in general. So far it will be seen that the work in no way departs from the beaten track of its predecessors, but, in fact, is still the "Artizan Club" treatise. Mr. Bourne has, however, modernized the work in his treatment of the subjects; he has introduced such emendations as render it consistent with the maxims and practice of the present day. The alterations in constructive form are fully indicated, although generally the descriptions are retained, Mr. Bourne's object being to have a record of former practice.

On looking through the work we were at first struck with the absence of any of the latest examples of engineering, which Mr. Bourne had so good an opportunity for introducing. But on reading the author's preface we were exceedingly glad to find that it had proved impossible to embody in the present treatise a vast amount of important information at the author's command. So we are promised a new work, supplementary to the present one, which will treat only of modern engines. When we add that their forms are to be minutely described, and illustrated by working drawings of a character so detailed that the engines may be made from them, our readers will be able to form some idea of the value of the promised work But with regard to the volume before us. we may observe that, embodying as it does those scientific principles which are of tolerably permanent application, it must ever remain the text book of the steam engine. As such we warmly commend it to our readers, who will find it to embody the results of the ripened experience of our leading engineers, and of the investigations of our professors and men of science. The present edition is well illustrated by thirty-eight beautifully drawn plates and five hundred and forty-six woodcuts. A capital portrait of the author faces the title page, and plate XIV. shows a sugar mill of improved construction, which is far superior to that illustrated in previous editions of this work.

Mr. N. P. Burgh is now engaged upon a new work on modern screw propulsion,† which promises to take its place as a standard book of reference on this subject. It is to be completed in fifteen monthly parts, two of which have already appeared. Mr. Burgh is assisted by a number of the leading engineering firms of England and Scotland, as well as by several professional gentlemen, and from this combination we may reasonably expect a sound practical work of abiding interest and value. The first chapter contains a series of preliminary considerations by Mr. Burgh, the second is the introduction to the general subject, and is written by Mr. G. B. Rennie, who gives an outline of the history of the screw propeller in England, and then touches on the various forms of propellers in use. He then discusses the question of the slip of the screw propeller, the effect of the angle, and depth of immersion, and finally the friction of the blades of screws in water. Mr. Burgh then takes up the theme, and devotes the third chapter to the geometry of the screw propeller, in the middle of which part II. leaves him. Each part is illustrated by two page plates and one folding plate of well executed lithographs, illustrative of the principles and practice of the subject. On the whole, we are led upon practical grounds to form a very favourable opinion of this work, and which will be enhanced if Mr. Burgh will only consent to withdraw nine-tenths of his inverted commas, and to give up the indiscriminate and senseless use of italics. He may depend upon it that this method of emphasising weakens far more

* "A Treatise on the Steam Engine." By JOHN BOURNE. Eighth edition. London: Longmans, Green, and Company. 1868.

Digitized by Google

than it strengthens the passage, especially when it extends to four words in a sentence, as in several instances before us. This, of course, is but a question of taste, and does not vitiate the practical value of the book, which, when complete, will be found to contain the best and most useful information upon the subject. From the character of the numbers before us we have no hesitation in commending the work to those of our readers who wish for information on the principles and practice of the screw propeller. Mr. Burgh has also published in pamphlet form a paper read by him before the Society of Arts, on the subject of the future development of marine engineering.* The author divides his subject into three parts, one of which he assigns to the boiler, another to the engine, and a third to the screw propeller, laying down principles for their further improvement. His conclusions are, that as heat is the prime mover, to it we must turn more of our attention, and, in place of 30lb., steam from 60lb. to 80lb. must be adopted for universal practice.

A very useful work has just been compiled by Mr. Washington Hudson, in the shape of a clear and concise treatise on practical geometry.† The want of such a work has long been felt by science teachers and their pupils, and Mr. Hudson, himself a Government science master, has supplied that want in the most exact and perfect manner. The work embraces all the branches of geometrical drawing applied in the arts and sciences, and it is so arranged as to be especially suitable for science classes. But, besides this, it will prove very useful to mechanics and workmen in various branches of trade; plane and solid geometry being united with orthographic, isometrical, parallel, and linear perspective projections in a clear and condensed form. A glance through this work shows it to possess peculiar merits in the direction we have indicated, and as its price places it within reach of the humblest artizan, we unreservedly recommend it. By its aid, persons having no previous knowledge of geometry may easily and thoroughly comprehend this science, and although there is no royal road to learning, Mr. Hudson has certainly rendered it uncommonly smooth, as far as geometry is concerned.

We have several other books for notice, which we are obliged, for want of space, to defer until our next number. We will, however, make one exception, and this for the purpose of endeavouring to set at rest, once and for all, a point upon which some misconception still exists, although we and others have done our best before now to place the matter in a right light before the public. The question is simply the position Mr. William Fothergill Cooke holds with regard to the introduction of the electric telegraph, of the honours of which position Mr. Cooke's friends assert Professor Wheatstone and his friends periodically attempt to deprive him. In other words, it is a question of Cooke v. Wheatstone, and we regret to see it again brought up, as almost every one had considered it finally settled. However, the honour lately conferred upon Professor Wheatstone appears to have been made the occasion of another pamphlet† by Mr. Cooke's friends. It is edited by Mr. Cooke's brother, the Rev. T. F. Cooke, who has sent us a copy, asking our notice of the matter. The pamphlet consists of a series of letters containing extracts from the arbitration evidence of 1841. If there should happen to be any who are unacquainted with the subject, and who desire to go into the matter, we would refer them to the pamphlet, but would not confine them to it, because there are two sides to the question.

To our mind, and to the mind of the scientific world, the case honestly stands thus:—When the arbitration took place many years since, it was then placed on record that Mr. Cooke had undoubtedly the merit of introducing the telegraph into Great Britain, and that in its general adoption he was materially assisted by Professor Wheatstone. The arbitration had reference also to the division of certain moneys arising from mutual patents, &c. When the Electric Telegraph Company purchased their entire rights, Mr. Cooke received £91,000 as against Professor Wheatstone's £33,000. Since then Mr. Cooke has been a director of the Electric and International Telegraph Company, and has never done anything further for the advancement of telegraphy scientifically. He has been content to rest upon his *golden* laurels, whilst Professor Wheatstone has been continually gathering laurels—not always golden in a pecuniary sense—for his many improvements in electrical science. Instruments, too numerous to mention, of which he is the inventor, are in general use, and he is ever active in bringing forward new things, not only in electricity, but in science generally. The honour of knighthood was conferred upon the Professor for his general scientific discoveries and inventions, and *not* because he introduced the telegraph, as Mr. Cooke's friends seem either themselves to think, or to fear others may think. To our mind, it is very questionable taste on the part of Mr. Cooke's friends to find another occasion on which to stir up old and long-settled questions, and to endeavour to make out that Mr. Cooke is a persecuted, an ill-used, and an injured man. There has never been, except in the minds of Mr. Cooke and his friends, any attempt to rob him of his just merits. They have everywhere, and at all times, been freely and willingly acknowledged, and full justice has always been done to him. If he is not content with his position in the matter, nor his friends with anything less than dragging him into unenviable notoriety, they must thank themselves for the results. We have, however, stated our views with regard to the case, and we believe they are those of the scientific world generally. We have now done with the question, and hope never to see it raised again. No practical good can be done to science by its further discussion, nor can it either add to or detract from the merits of either Mr. Cooke or Professor Wheatstone with respect to the introduction and development of the electric telegraph in Great Britain.

ELECTRICITY AND TELEGRAPHY.

THE Chancellor of the Exchequer gave notice on Monday last that he should move for leave to introduce a bill to enable the Postmaster-General to obtain possession of the electric telegraphs throughout the country. The bill was brought in and read a first time last evening. We hope in our next impression to discuss the principal points in the bill.

We have lately been unfortunate with regard to our submarine cables, many of which have been broken. The Persian Gulf cable was broken on the 14th inst. between Mussendom and Gwadur; during the interruption, which is not expected to last long, messages are conveyed over the interrupted section by steamer. The Dover and Calais cable is again broken, an accident having happened to it during one of the recent storms; messages are sent by the Boulogne and Dieppe route.

The Portpatrick and Donaghadee cable has just been repaired after an unusually protracted breakdown; the operations were materially interfered with by the weather, and the cable itself being old and very weak, rendered care most necessary. The picking up entailed a great amount of time, for the cable parted wherever it was grappled, and it was some time before a sound piece could be buoyed. A further delay was occasioned by an accident to the cable during the paying out. It is intended to strengthen the shore ends of the cables that go across these straits. The Malta and Alexandria cable is still interrupted, messages in the meantime coming by the Syrian route, but frequently with great delay. The repairs to this cable have been greatly lengthened on account of the very bad weather. The Isle of Wight cable, which was lately interrupted, has just been repaired and put in working order.

The Telegraph Construction and Maintenance Company have issued their report, recommending a dividend at the rate of 5 per cent. per annum. Their past year's operations consisted in laying the Placentia and Sydney cable, a length of 320 miles, and of twice repairing the Atlantic cable. The first repairs were effected in an unprecedentedly short time, communication having been restored three weeks after the agreement was signed. The fault occurring off Newfoundland rendered a long sea voyage necessary, occupying a large amount of the above time. The second fault occurred whilst the "Chilterns" was engaged in the Placentia cable, a fact that was very fortunate, as it did not necessitate a vessel being sent over specially. With regard to these repairs, the report remarks that "they have an important bearing upon the practicability and economy with which submarine telegraphs can be maintained, and the experience gained forms a very valuable addition to that acquired in the Atlantic expeditions of 1865 and 1866."

In order to improve their means of communication with the East, they have taken steps to consolidate and improve the company's property in Italy, the Mediterranean, and in Egypt. "With this object, and in order to obviate the delays arising in telegrams passing through continental countries, the company are erecting a land line, connecting Susa in Italy with Modica in Sicily, which will greatly facilitate the transmission of dispatches. This line, it is hoped, will be open in June next." They have every hope of obtaining the contract for the Tasmania Victoria cable. They, with ourselves, hope that the depression as regards business generally, and more particularly with regard to cable business, is only temporary, and that submarine telegraph enterprise must revive, especially "when the well-known fact is taken into consideration that large as are the present receipts from all telegraph lines, the greater proportion of the profit is being realized from the Atlantic and other submarine cables."

An important meeting was held on Monday last at the Mansion House, to consider the question of telegraphic communication with the East, in reference to a memorial addressed to Sir Stafford Northcote, signed by numerous leading houses in the City, and presented by the Lord Mayor. The prevailing feeling throughout the meeting was in favour of a submarine line, viâ the Red Sea, to India, as one speaker deprecated the idea of a land communication as being "essentially unsound, dependent as we were at the present time on the goodwill of foreign countries, and circumstances might arise that might absolutely cut us off from all communication with India." Some went so far as to revive the old scheme of a submarine line all the way from England to Egypt, and from thence by the Red Sea route. Whilst complaining of the delays relative to the Abyssinia war, and the saving of time if there had been a submarine cable, it was rather unfortunate—a fact that seemed to be lost sight of—that a great part of the delay was owing to an interruption in one of the links of the chains so strongly advocated. There is no doubt that the meeting will do good by agitating the question of our Indian telegraphic communication, to which we so lately alluded, and we hope shortly to see means adopted for enabling us to obtain earlier as well as more certain intelligence.

The Electric and International Telegraph Company have lately contracted with the India-Rubber, Gutta-Percha, and Telegraph Works Company for the manufacture at their works, at Silvertown, of thirty-three miles of cable, for renewals in the North Sea. A portion of this is to be shore end of the great weight of seventeen tons to the mile. The core is now being commenced at the same works.

General Smith, the President of the American Company—the International Ocean Telegraph—is now over here with regard to making arrangements for the manufacture of a second cable to connect Cuba with Florida, and some mention has

Digitized by Google

been made of laying it this summer. We trust we are misinformed on that point, for after the experience obtained last year, when the vessel arrived out there in the middle of the hot season, and with yellow fever in every direction, from which the staff suffered so severely, such an undertaking would be foolhardy in the extreme, and we cannot think that any contractor would undertake submerging a cable at such a time.

A great improvement has been effected in Wheatstone's Automatic Telegraph by Mr. Culley, in the preparation of the punched paper ribbon for this system of telegraphy. In the ordinary way the punches are struck by pieces of vulcanite held in the hand, but Mr Culley has placed above each punch a small cylinder containing a piston acted upon either by vacuum or compressed air. The valves are worked by finger keys as light in their touch as those of a pianoforte, and the result is that "punching" is effected with the greatest ease and at a much more rapid rate. The apparatus is manufactured by Mr. Stroh, of the Hampstead-road.

The necessity for another cable is a striking proof of the amount of business that must take place between Cuba and the States. We trust shortly to hear of the proposed extension to Panama

Professor Grove tried lately a novel experiment with a small induction coil of 3¼in. long by 2in. in diameter, containing a secondary wire of about three-quarters of a mile in length. To the primary wires of this coil he connected the wires from a small medical magneto machine. The contact breaker of the coil was closed, as the success of the experiment was considered to depend upon that. On setting the machine in motion no effects whatever were observed in the secondary wire, and it was only when the contact breaker was released and allowed to work as usual that any results were obtained. He then obtained sparks about three-quarters of an inch in length, and vacuum tubes were readily illuminated. The result is, he states, dependent in some manner upon the condenser, for without it no effects are obtained. It must be borne in mind that the currents obtained from these small magneto machines are of a rapidly alternate character, and that they would probably neutralize each other. The experiment might possibly be different if a commutator were used, and the currents passed into the coil in one direction only. The rapidity of the currents induced would then probably answer similar to a contact breaker. With the contact breaker in rapid action, is it not probable that the opposite current of the machine was cut off and neutralized, and that the usual effects followed similar to a single current?

NOTES ON RECENT SCIENTIFIC DISCOVERIES AND THEIR PRACTICAL APPLICATIONS.

AN IMPROVED SAFETY LAMP—DANGERS OF LEADEN TOBACCO BOXES—INKS FROM ANILINE COLOURS—MODE OF SUBMITTING IRON CASTINGS TO PRESSURE WHILE THE METAL IS IN THE LIQUID STATE.

At a recent meeting of the Société d'Encouragement, a description of a new safety lamp for use in coal mines, petroleum warehouses, distilleries, &c., was read. Practically speaking, there is nothing very original in this invention, but the arrangement of the parts is new. Around an ordinary oil lamp an iron crown is fixed by means of a bayonet catch. This crown is pierced with holes to supply the air, the holes being fitted with fine wire gauze. Above this crown is another of thick glass, which allows the light of the flame to pass, and above this again is the chimney or cylinder of fine gauze, the mesh of which is the same as in the Davy lamp. We do not suppose this lamp is more safe than the Davy lamp, but it will give more light, and will not be expensive.

Leaden tobacco boxes, we believe, have nearly disappeared in this country, but we see some occasionally, and we may therefore quote the observation of Dr. Mayer, of Berlin, who states that he has traced six cases of lead colic and paralysis to the use of these utensils. M. Chovallier has also found that tobacco wrapped in lead foil becomes impregnated in the course of time with acetate of lead.

Fuchs describes a method of making of inks with the aniline colours which may be useful to some of our readers. He takes a quarter of an ounce of the colour required—red, blue, or yellow; but as the strength of the colours of commerce varies, a little more or a little less must be used at times to keep up uniformity of shade. The colour is digested for some three hours in two ounces and a-half of strong alcohol. Then a pint and a-half of distilled water is added, and the whole is gently heated, until all the alcohol has been driven off. An ounce of gum arabic dissolved in eight ounces of water is then added, and after standing for a time for any impurities to deposit, the ink is ready for use.

A mode of submitting iron castings to great pressure, while the metal is in the liquid state, has been devised by M. Galy-Cazalet with the idea of giving thereby greater strength to steel cannons. The way of making the mould we need not describe, as it appears to be the same as usual, only using an outer iron casing of greater strength. As soon as the metal has run into the mould, M. Galy-Cazalet fixes firmly on the top a metallic cap, so as to seal the mould hermetically. The cap carries a tube which can be opened by means of a stop-cock. Within the tube, which is closed at the top, a few grammes of a powder composed of charcoal and nitre is put. When the stop-cock is opened this powder falls upon the liquid metal, and developing a quantity of gas at a very high temperature great pressure is necessarily exerted upon the metal. Thus the casting is obtained perfectly solid, and the gun will consequently possess far greater strength than an ordinary casting. This system of casting may perhaps be applied with as much advantage to many other things besides cannons.

THE FORMS AND PROPORTIONS OF IRON-CLADS.

By Mr. E. J. Reed, Chief Constructor of the Navy.

The following is an abstract of a paper read at the Royal Society, on the relation of form and dimensions to weight of material in the construction of iron-clad ships, on Thursday, March 19, 1868. The object of the paper is to show that the proportion of length to breadth in a ship, and the form of her water lines, should be made in a very great degree dependent upon the weight of the material of which her hull is to be constructed—that an armour-plated ship, for example, should be made of very different proportions and form from those of a ship without armour, and that as the extent and thickness of the armour to be carried by a ship are increased, the proportion of length to breadth should be diminished, and the water lines increased in fullness.

It is highly desirable that this subject should receive the attention of men of science, not only because it bears most directly upon both the cost and the efficiency of future iron-clad fleets, but also, because it opens up a theoretical question, which has hitherto, the author believes, received absolutely no consideration from scientific writers upon the forms and resistances of ships, viz., the manner in which the weight of the material composing the hull should influence the form. Prior to the design of the "Bellerophon," the forms of ships were determined in complete disregard of this consideration, and even the most recent works upon the subject incite the naval architect to aim always at approaching the form of least resistance. The investigations given in the paper show, however, that the adoption of a form of least resistance, or of small comparative resistance, may, in fact, lead to a lavish outlay upon our ships, and to a great sacrifice of efficiency; while, on the other hand, the adoption of a form of greater resistance would contribute in certain classes of ships to great economy and to superior efficiency.

In order to indicate clearly, but approximately only, the purpose in view, the author first considers the hypothetical cases of a long and a shorter ship, both of which are prismatic in a vertical sense. The length of the long ship is seven times its breadth, and its horizontal sections consist of two triangles set base to base. The length of the short ship is five times its breadth, the middle portion being parallel for two-fifths of the length, and the ends being wedge-shaped. It is assumed also, that at a speed of fourteen knots, the long ship will give a constant of 600, and the short ship a constant of 500 in the Admiralty formula,

$$\frac{\text{Speed}^3 + \text{Mid. Section}}{\text{Indicated Horse Power.}}$$

The draught of water is in each case 25ft., and the total depth 50ft. It is taken for granted that the form of the long ship has been found satisfactory for a ship of such scantlings that we may consider her built of iron of a uniform thickness of 6in., the top and bottom being weightless. Now let it be required to design a ship of equal speed, draught of water, and depth, but of such increased scantlings (whether of hull proper, or of armour) that the weight shall be equivalent to a uniform thickness of 12in. of iron, the top and bottom being weightless as before. First, the new ship has the proportions of the long ship given to her, and secondly those of the shorter ship. In each case the engines are supposed to develope seven times their nominal horse-power, and to weigh (with boilers, water, &c.), 1 ton per nominal horse-power. The coal supply in each case equals the weight of the engines, so that both ships will steam the same distance at the same speed. But as the equipment of the smaller ship will be less weighty than that of the larger ship, we will require the larger ship to carry 2,000 tons, and the smaller 1,500 tons additional weight.

Assuming the breadth extreme in each case to be the unknown quantity, we can, from the Admiralty formula given above, deduce an expression for the indicated horse-power; thence under the assumed conditions the weights of engines and coals can be found; and these being added to the weights of hull (calculated on the assumption that the sides are of 12-in. iron) and to the weights carried, give an expression for the total displacement, in tons, of each ship. Another expression is found for this displacement by finding the weight of water displaced. The two expressions are equated, and a quadratic equation is formed, from which the breadth extreme is determined, and from it all the other values can be found. The accompanying table shows the results obtained by this method for the two classes of ships:—

	Long Ship.	Shorter Ship.
Length, extreme.....	581 feet	342 feet
Breadth „	83 „	68¼ „
Nominal horse-power.....	1,350H.P.	1,337H.P.
Indicated „	9,450 „	9,359 „
Weight of hull	12,570 tons	7,576 tons
„ of engines	1,350 „	1,337 „
„ of coals	1,350 „	1,337 „
„ carried	2,000 „	1,500 „
Total displacement.....	17,270 tons	11,750 tons

It will, therefore, be seen that by adopting the proportions and form of the shorter ship, a ship of the required scantlings and speed will be obtained, on a length of 342ft., and a breath of 68¼ft.; whereas if the proportions of the long ship are adopted, the ship, although of the same scantlings and speed only, will require to be 581ft. long, and 83ft. broad, the steam power in both cases being as nearly as possible the same. Considerations of this character worked out more fully, led the designer of the "Bellerophon" to depart so considerably from the form and proportions of the "Minotaur."

The next part of the investigation is based upon the official reports of the measured mile trials of the "Minotaur" and "Bellerophon," when fully rigged, and upon calculations made from the drawings of those ships. It is assumed that a prismatic vessel having the same mean draught as each of these ships, and having the same form and dimensions as the mean horizontal section—which equals the mean displacement in cubic feet, divided by the mean draught of water—will give the same constant as the ship herself at the assumed speed of fourteen knots, which, as nearly as possible, equals the speed obtained by both the "Minotaur" and "Bellerophon" on the measured mile. For each ship the weight of the armour and backing is supposed to be uniformly distributed over vertical prismatic sides of the dimensions of the armoured sides, and the weight of hull is similarly distributed over vertical prismatic sides of the dimensions below water of the mean horizontal section, and above water of the armoured side. The actual weights carried by the ships are thus transferred to, what may be termed representative prismatic vessels, having the same constants of performance as the ships. The detailed calculations in the paper show that the weight per square foot of the material in the hulls of the two ships, when distributed over the sides of the representative prismatic vessels, is very nearly the same for both, and the same holds with respect to the weight per square foot of armour and backing. The "Minotaur" is rather heavier in both respects, but for the reasons given in the paper, the means of the values found for the two ships are taken, and are found to be—

Digitized by Google

Weight per sq. foot of hull . . = ·152 ton
" " armour and backing = ·11 ton.

The questions next considered are these: presuming it to be necessary to build another ship which shall also steam fourteen knots, carry the same proportionate supply of coal to engine power, and proportionate quantities of stores, but shall have her armour and backing of double the weight of armour and backing of the "Bellerophon" and "Minotaur," then first, what will be the size, engine power, and cost of the new ship of the "Minotaur" type, and having the same mean draught and depth of armour; and second, what will be the size, engine-power, &c., if built on the "Bellerophon" type, and having her mean draught and depth of armour? this condition implying of course that the same constants of performance as before will be realized in each case. On account of the great disproportion in size between the two types of ship it is obvious that the smaller one will require much less weight of equipment. It is assumed therefore that the additional weights of the smaller ship (exclusive of engines, boilers, and coals) amount to 700 tons, and those of the larger ship to 1,000 tons. The developed power of the engines, proportionate supply of coal, and the weight of engines, &c., are taken exactly the same as in the hypothetical case first given.

By proceeding with the investigation for each case in a way similar to that sketched for the hypothetical ships, only treating the breadth extreme of the mean horizontal sections of the new ships as the unknown, the following results are obtained. The new ship of the "Minotaur" type which fulfils the required conditions will be nearly 490ft. long, 72½ft. breadth extreme, and have a total displacement of 14,253 tons; while the new ship of the "Bellerophon" type is 380ft. long, 71ft. breadth extreme, and has a total displacement of 10,950 tons. It thus becomes obvious that a correction is needed in the weight per square foot of hull in the new ship of the "Minotaur" type, as her length has been so greatly increased; it is considered that an increase of at least 10 per cent. is required, and this is the allowance made. On the other hand, the new ship of the "Bellerophon" type is still shorter than the "Minotaur" herself, and the displacement is not much greater than the actual displacement of the "Minotaur," so that no correction is needed in her weight per square foot of hull. When the correction has been made for the new ship of the "Minotaur" type, the final results in round numbers are as follows for the two classes of ship:—

	New Ship of Minotaur type.	New Ship of Bellerophon type.
Length	510 feet	380 feet
Breadth	75 "	71 "
Tonnage	13,770 tons	8,620 tons
Nominal horse-power	1,080 H.P.	1,080 H.P.
Indicated "	7,560 "	7,560 "
Weight of hull	7,100 tons	4,460 tons
" armour and backing	5,190 "	3,630 "
" engines and coals	2,160 "	2,160 "
" stores carried	1,000 "	700 "
Displacement	15,450 tons	10,950 tons

Taking the cost per ton at £55 (which is the average cost per ton of tonnage for the hulls of armour-clad ships), the saving made by adopting the new ship of the "Bellerophon" type would amount to £283,250, or considerably more than a quarter of a million sterling. It must also be considered that the ship of the "Bellerophon" type would cost less for maintenance and repair, and be much handier in action.

The last investigation in the paper is purely theoretical, and consists of a determination of the dimensions which would be required in two ships, of which the horizontal sections are curves of sines, and which are prismatic vertically, if they were built with the same weight per square foot of hull (say ·1 ton) as the "Bellerophon," but carried twice the weight of armour per square foot (say 6·28 ton). In these cases the bottom is taken to have weight as well as the sides, the speed for both is fourteen knots, the draught of water is 25ft., and the depth of the armoured side 24ft. One of the ships is seven times her breadth in length, and the other is five times. Professor Rankine's rule for the calculation of horse-power and speed is employed, and the same conditions of engines, &c., are assumed, as have been indicated previously. The larger ship carries 1,350 tons additional weights, and the smaller 900 tons. The results obtained for these ships are as follows, when expressed in round numbers:—

	Larger Ship.	Smaller Ship.
Length	585 feet	425 feet
Breadth	84 "	85 "
Nominal horse-power	1,267 H.P.	980 H.P.
Indicated "	8,890 "	6,860 "
Weight of hull	7,586 tons	5,540 tons
" armour and backing	6,124 "	4,470 "
" engines and coals	2,540 "	1,960 "
" carried	1,350 "	900 "
Displacement	17,600 tons	12,870 tons

These results are very different in detail from those obtained in the cases based on the actual trials of the "Bellerophon" and "Minotaur," but not greater than might have been anticipated from the adoption of such a different form of ship, and mode of calculating resistance. The 2,000 horse-power which is needed by the larger ship above the power required by the smaller ship, is principally due to the difference between the immersed surfaces of the two ships, and is spent in overcoming friction. The immensed midship sections, it will be remarked, only differ by a very small amount. This last investigation serves to show that the theoretical best form of ship being taken, and the most recent rule being applied in the calculations, the speed of 14 knots can be obtained in the short type of ship at a surprisingly less cost and size than the long type requires, and this result agrees with that of the preceding investigation based on actual trials.

ON THE SHRINKAGE OF CAST IRON.

THE following is the substance of a paper read by Mr. David Walker before the members of the London Association of Foremen Engineers on Saturday, the 4th inst., Mr. Newton in the chair:—Shrinkage is the complement of the property which metals possess in common with nearly all other bodies—that of expanding by heat. It comes into operation more or less at all ranges of temperature, but varies very much in degree. In iron castings it proceeds very rapidly at temperatures high above the smelting point, which was proved by the sinking of the metal in a mould after it had been filled, and the large quantity of metal which was required to keep up the head—technically called "feeding." This would go on in castings of great thickness for a couple of hours or more. When this subsidence was not guarded against by the feeding operation, the castings inevitably became unsound. Exteriorly it would take the form of the mould, but in the centre it would be hollow; the experienced moulder so arranged his feeding head as to supply those parts of the casting which were thicker than the others. (The reader here introduced a piece of cast iron caught, as it were, in the act of crystallization, and which presented an appearance analogous to that of water when freezing.) Mr. Walker then proceeded to say that whereas water expanded during crystallization, iron shrank. A block of metal measuring 1¾ cubic feet took about 7lb., or 26 cubic inches, of metal to feed it; this was equal to 1-10in. to the foot, the usual allowance made for shrinkage in cooling from the smelting point. This appeared to confute the idea of iron expanding in the act of crystallization. It had been said to expand externally; he had never been able to observe any symptoms of this nature. If there were any of that irresistible power which ice exhibits, we should expect it to show itself in the case of a chilled roller, for example. This was not so to any perceptible extent, the chill or iron mould lasting till fairly worn out by heating and cooling. The only argument for the theory of iron expanding in crystallization, held by some scientific men, was that the solid was supported by the fluid, thus showing greater specific gravity.

That the metal shrank while cooling in the fluid state was beyond a doubt, and that the fluid supported its own solid was also quite clear, although how to reconcile the two facts he was at a loss. The contraction, however, was checked during the loss of a great portion of the heat, which was not easy to be accounted for, unless we looked upon the expansion by crystallization, on the one hand, and the contraction by loss of heat, on the other, as two great opposing powers, which, like the centrifugal and centripetal forces in the heavenly bodies, balanced each other for a time, and thus checked the action in either direction. Mr. Walker observed that he had no desire to indulge in theoretical speculations, but would prefer to give the results of his own observations, extending over a considerable time, and sometimes producing rather conflicting ideas. It was admitted, as demonstrated by researches in chemistry, that fluids began to crystallize at certain fixed temperatures, varying according to the properties they possessed. Cast iron, for example, was given at 2,754deg. Fah. by some authorities; at 3,600deg. by others; whilst some authorities went even as high as 17,975deg. by the same thermometer. Copper was less, and the scale descended in silver, gold, zinc, lead, &c., down to mercury, which was 39deg. below zero. Now, leaving out of the question for the present the numerous qualities of cast iron, it would seem safe to assume that two castings from the same charge would crystallize at the same temperature, and if the shrinkage could be calculated with any degree of certainty, our task would be comparatively an easy one. This was, however, by no means the case, for it was influenced by very many conditions—as thickness, position, the nature of the mould (whether of loam or sand) in its various forms, and others, which baffled calculation. He (Mr. Walker) did not expect to succeed in arriving at any definite points as to the results of these conditions, but that even an approximation was important would be admitted by experienced pattern makers, who often found great difficulty in causing the various castings of large pieces of work to come to the required sizes, they having to be produced under the varying conditions alluded to.

The simplest form of casting, and that most easy of observation—the open sand plate—on being poured solidified very quickly, and parted with its heat rapidly. It would naturally be expected that in this case shrinkage would proceed in proportion, but this was by no means so. About ten minutes after it had become set it would be below the smelting point of copper, showing that it had, by the lowest estimate, lost 700deg. of heat, but there was no observable contraction. It would remain at its original size, varying according to thickness, perhaps half an hour, and then it would begin to shrink very slowly indeed till it had cooled to about 1,100deg. or 1,200deg. Here the contraction would cease for a time, and at this peculiar temperature a decided expansion would take place, and this existed until it cooled to about 800deg., when the real work of shrinking began. That slowness of contraction at high temperature he had noticed, in a general way, frequently, but the observations in regard to temperature and the discovery of expansion, at a particular degree of heat, was made upon a plate of cast iron 14ft. long and 1½in. thick, and this was cast at ten minutes to three o'clock in the afternoon, and it set almost immediately. About ten minutes after, it had cooled below the smelting point of copper, and must have lost, according to the lowest estimate of temperature, upwards of 700deg. of heat. This it did without showing the slightest symptom of shrinkage; nor did it do so for quite half an hour, then shrinkage began to show itself very slowly, and continued until it reached the amount of 3-16in. in 14ft. length. Judging from the colour, it had now come to the temperature of about 1,100deg. or 1,200deg. Strangely enough, at this point it began to expand again, and recovered one-eighth of its lost dimension, and thus it remained till it had fallen to about 900deg., when the contraction proper began, namely, about two hours after casting. In one hour it amounted to 5-8in., heat about 700deg. Next hour, 7-8in., heat 600deg. Next hour, 1 1-16in., heat about 550deg. Judging from its effects upon metals of known degrees of heat at the fusing point, next morning, at six o'clock, the heat was 130deg. by the thermometer, the shrinkage 1 11-16in. Finally, the contraction had reached 1¾in., or exactly 1-8in. to the foot. There were some very curious phenomena to be observed upon in this example. It lost nearly 2,000deg. of heat without sustaining any longitudinal or appreciable shrinkage. This might or might not be accounted for by the idea suggested—that of the opposing forces, due to expansive crystallization on the one hand, and shrinkage, by loss of heat, on the other. It was clear that nearly the

Digitized by Google

whole of the shrinkage took place within the range of 600deg. The reader of the paper said he had made numerous observations with similar results.

The most important condition, as affecting shrinkage, was, he thought, the relative thickness of castings. Two castings, poured at the same time, would yield very different results in shrinkage when they varied in thickness. It would be easy to adduce examples of this, and one should be mentioned. A bar of cast iron, 1in. thick and 3ft. long, gave 1-10in. per foot of contraction, while a block, cast from the same cupola, and within five minutes of the same time, gave in 2ft. length no shrinkage at all! The latter, indeed, when cold, was exactly of the same dimensions as the mould. The measurements were made with great care in both cases. What seemed more remarkable perhaps was the fact that the same block took in feeding, as nearly as could be estimated, a quantity of metal equal to 1-10in. per foot in its whole mass. These experiments agreed in their main features with the author's general experience, and showed that block castings do not, as a rule, shrink to any sensible extent. Generally, he had found that castings which were fed well had a very limited degree of shrinkage. It would be possible for him to make a sketch of a frame with which he was very familiar (a finely proportioned pattern 2¼in. thick), in which the contraction of the resulting casting varied from 1-17in. to 1-23in. per foot longitudinally, and in depth, which was 24in., gave no shrinkage at all. This was a casting with flanges all round it, so that there was no part of the results due to straining. They were attributable to careful feeding alone. In conclusion, Mr. Walker remarked that this subject naturally divided itself into two parts—First, the nature and condition of shrinkage proper; and, second, the effect of unequal contraction in ill-proportioned castings. The first of these he had hoped to deal with fully that evening, but found that want of time prevented it. At a future period it should be resumed, and then it was to be hoped the whole subject might be more satisfactorily developed.

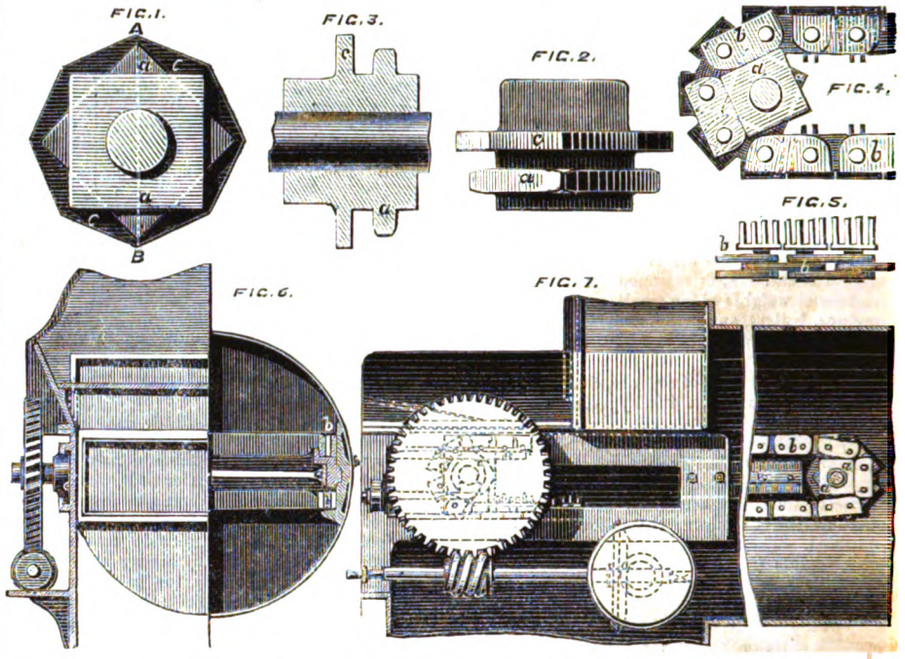
THE STEAM MAN.

THE advent of a steam man in New York has added another to the novelties in that sensational city. The steam man is a new locomotive for common roads, invented at Newark, New Jersey, and is intended to walk or run about as a man would and draw carriages after it. According to the "Times," the particular steam man who is now astonishing New York is a person of commanding presence, 7ft. 9in. high, weighing 500lb., measuring 200in. round the waist, and decidedly stout in general appearance. His legs are made up of iron cranks, screws, springs, and other intricate machinery, and have a motion similar to the human extremities; his stomach is a furnace, his chest a boiler, and the smoke passes up through his head and towering hat. He bears a good-humoured countenance, with a handsome moustache, while in his mouth is fixed a steam-whistle, and a gauge and a safety valve ornament the back of his head. He is the figure head, as it were, of a phæton, capable of accommodating four persons, together with a tank to carry water and a box for coals. The driving machinery is at his back, and within easy grasp of the persons on the phæton, who can start, stop, carve, go fast or go slow at their pleasure. The inventor claims that 20lb. of steam will set him in motion, and 20 cents worth of coal work him a day. He also claims that he can accomplish a mile in two minutes on a level course, and can step over all obstructions not higher than a foot. His engine is 4-horse power, and the man takes 30in. in at each stride. This steam man, however, has not yet exhibited himself in public, though he is promised a race down Broadway when the weather is fit, and meanwhile his owner offers to manufacture steam men at short notice for 300 dollars apiece. Whether they prove of any practical good or not, the one at New York is unquestionably a great curiosity, and when we have said this we think we have said all that can be said.

THE public accounts for the financial year 1866-67 show that from Hyde Park £477 was received in contributions for keys; from Kensington Gardens £140 for grazing rent; from the Green Park 31s. 6d. for keys; from St. James's Park £83 for grazing rent, £220 for rent of ground, and 22s. by sale of unclaimed articles found in the Park—an item that does not appear in the accounts of other parks; from the Regent's Park £349 for keys, £410 for grazing rent, and £336 for rent of ground. £452 was received in fees on warrants for venison supplied from the Royal parks, and proceeds of sale of skins, &c., of deer; and £184 was paid to the keeper of Bushey Park in fees for deer killed in the park.

IMPROVED PULLEY AND CHAIN GEARING.

BY MR. T. WRIGLEY.



IMPROVED PULLEY AND CHAIN GEARING.

WE illustrate in the annexed engraving a novel description of pulley, which is the patented invention of Mr. Thomas Wrigley, of Todmorden. In combination with a chain specially designed it may be applied to many purposes where lifting, pulling, the moving of firebars in furnaces, or the driving of machinery, are effected by means of chains and pulleys; in fact, wherever the pulley is required to take firm hold on the chain to effect its positive and certain action without slipping. The principle consists in constructing the pulley so that the chain shall have several holds on the surface, the number of which may be increased or diminished according to the strength of links or width of chain and the weight to be moved.

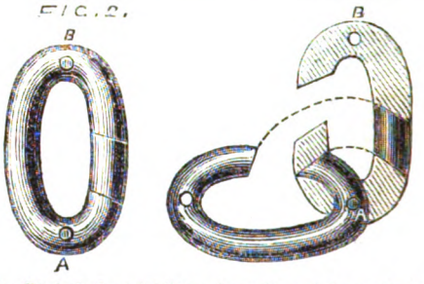
As an example of the invention, we have shown it as applied to the moving of the transverse gratebars of a furnace. Fig. 1 represents an end view of the pulley which contains plates or surfaces of two forms, one set, *a a*, being square for the bearing of the links *b b* (which are dotted as in position), and the end plate *c* being octagonal for the bearing of the bars when applied to the firebars of furnaces, because the width of two bars being equal to the length of one link the bars require more faces to bear upon than the links. Fig. 2 is a plan view, and fig. 3 a vertical section of the pulley taken through the line A B, and fig. 4 is an end elevation showing the application of the pulley and chain to the transverse furnace bars; fig. 5 is a plan view of the same, which in this instance shows the pins or studs on the ends of the bars as forming part of the chain, but in ordinary chains applied to other purposes the links are jointed together by pins as usual.

It will be seen that the plates are so arranged that the points or angles of one plate project above the flat surface of the next, and so on alternately, which is an important portion of the invention, as the projecting points or angles form guides or lateral supports for the links, and the pressure of the chain is dispersed over a greater surface, and presses from several points arranged around and towards the centre shaft instead of the strain being in one line from the outermost point diametrically to the centre, by which improved arrangement the turning of the pulley requires less power, the friction being more evenly distributed. The progress of the chain is effected by the angles of the plates entering the apertures between the joints of the links in combination with the bearing of the links on the flat surfaces of the pulley, and whatever may be connected with such chain will receive motion and power therefrom.

Figs. 6 and 7 show the application of this invention to the firebars in the furnaces, at the Robinwood Mills, Todmorden, owned by Messrs. Fielden Bros., and of which works Mr. Wrigley is the manager. The apparatus has been working for some months with perfect satisfaction. The mechanical details are well carried out, and not one instance of slipping has occurred. The furnace is at once self-feeding and smokeless, and the apparatus requires a remarkably small amount of power to keep it in motion.

LINKS FOR TRACTION AND SUSPENSION CHAINS.

TO unite the two extremities of chains to those of others, in order to constitute an "endless arrangement," and to replace a fractured link, are circumstances of continual occurrence where machinery is employed. Various methods are in use, but it is questionable whether they afford the solidity and strength desirable. Some time ago M. Crauzbaur, of New York, patented a form of link calculated to give the maximum amount of resistance to a change of form, while undergoing a strain, and also presenting a complete security against opening. When once closed they cannot be caused to open so as to allow the neighbouring links to be disunited. The annexed cuts, which we extract from our contemporary



"Le Génie Industriel," nearly suffice of themselves to render their action clear and intelligible. Fig. 1 represents the link open, and fig. 2, when it is closed. It is composed of two parts absolutely identical, whether the link itself be made of round or flat iron. In each part a piece is cut out to receive the corresponding projection upon its neighbour, the "fit" being made with great accuracy and precision. A rivet is inserted at A, upon which the two halves pivot, and when they are closed, as shown in fig. 2, the union is permanently effected by means of a bolt, rivet, or screw inserted at B. It will be seen that the principle can be applied to a link of any form, whether simple or complicated.

NAUTICAL TERMS.

WE lately gave our readers a couple of disquisitions on scientific nomenclature, and thought we had exhausted the subject. The following playful effusion, however, would indicate that we have not. It is from a reefer in the American navy to the Hon. Matthew Walker, and we reproduce it from the United States "Army and Navy Journal." The reefer appears to be considerably bothered as

Digitized by Google

to the reason for certain terms and expressions which are generally used on ship-board. Old salts will laugh at the writer's blunders, but landsmen may learn something by reading this effusion. The letter is dated on board ship, February 18, 1868, and, after the usual preliminary greetings, goes on to say:—

To you and Mr. Half-Hitch I am indebted for many useful ideas, which my old grandmother learned from her aunt. And as I have seen service both with the lay and against it, and, besides, knew when I used to sail kites (I was a kite-sailor then) how to tie two strings together, to you two gentlemen I say that I am deeply indebted; and also to other authors on seamanship. All these authors speak of ear-rings and thimbles, hence we must conclude that a ship has ears as well as fingers, but I must confess that I never saw them. The boatswain told me that the topsails had ear-rings, and I asked him if they had any ears; he told me I was a fool, and that was all the satisfaction I could get.

Well, now, there is another curious thing that I would like to mention: this ship has a fore-yard and no back-yard. Then, again, the boatswain calls a great big piece of rope a sheet, although my old grandmother has often told me that a sheet was a piece of muslin, to put over a bed. Again, there is another singular fashion that they have on board ship. I asked the boatswain what some large tarry ropes were called; he answered shrouds. Now, when my old aunt died, they put her in a white night-gown, which my mother called a shroud, and I think that she was right. I asked him the reason for giving them this queer name; he answered, "Don't you see that they go around the dead-eyes?"

Another thing that I never could understand before I went to sea, was that a little stick was called a batten; but understood it when I arrived in Brest; there I unintentionaliy offended a Frenchman, by telling him in excellent French that, "*Votre ami a perdu son vic.*" He did not understand English, or French either, for he flew into a great passion, and said in broken English, "I shall break ze head *avec mon baton.*" And as good as his word he rapped me over the skull with his cane. So I concluded that batten must mean stick or cane. So we should then in propriety give the order to cane or stick down the hatches, which order I have no doubt many of our reefers would be willing to obey in bad weather. It seems to me that this order should never be given to the carpenter, but to the surgeon, purser, marine officer, and others who have the happy faculty of sticking down the hatches whenever bad weather comes on. The chaplain might also be considered a candidate for this honour.

The most curious fellow we have on board is the master. He takes the lead in finding bottom, and he is continually feeling for it. I cannot say much for his manners, for he has always such a stern way on him when he gets it. As for the gunner, I think it doubtful whether he is the most modest or immodest man on board; he is certainly very inconsistent, for his guns have aprons and breeches and locks, and he very often lets down their breeches, takes off their aprons, and adjusts their locks in the most public manner. Should I ever get a chance I will read him a lecture on the breaches of modesty, who is generally represented as a woman in a long gown. I did not say frock, for sailors' frocks are generally short shirts, and I fear that I might be misunderstood, for if modesty should wear a sailor's frock, the artists would certainly have to give her a gunner's apron, which is warranted to be proof.

Whenever I read a book on seamanship I am obliged to consult my dictionary. I find often that they do not agree. For instance, a yeoman, according to the dictionary, is a countryman, a peasant, while, according to all books on seamanship, he takes care of the ship's stores, the rope, tar, nails, &c., &c. The carpenter deals in fishes, and the boatswain deals in cats, fishes, tar, and has but little to do with the boats. The carpenter and boatswain mess together, and such a mess they make of it, with their cats and fishes, I would defy any cannibal to eat them; for, if he should eat the boatswain's cat, he would certainly be bound up; and the carpenter's fish is entirely indigestible; it does not look like a fish at all, and I don't see how any one could call it so. I sent a specimen of one of his fishes to a celebrated *savant*, to be analyzed, and he sent back the following formulæ: C24, H20, O20, K, E. These symbols were examined by the boatswain, and pronounced correct; but a dispute arose atwixt the sailmaker and carpenter about it. The carpenter contended that the *savant* intended to spell chock, and he had made a *lapsis plumæ*. But the sailmaker rejoined that the *savant* had made no mistake at all, but he meant to say that if any one should eat the carpenter's fish, he would choke. But the boatswain settled the difficulty by putting a stop to it, I mean to the symbol, after the H. Thus: C H. OKE. "It is very clear," said he, "that your fish was made out of oak, and the manner of spelling it don't make any difference, for you know that all these chemists are Dutchmen or Frenchmen, and it could not be expected that they should know how to spell." But the carpenter asked him about the meaning of the C, H. The boatswain replied with an oath, "Why, you fool, don't you know that your fishes go under the cat-harpins, and what else can it mean but that?"

The master suggested that it might mean Robar Carolus, out of which the southern cross was made; but they all sneered at him and took the boatswain's explanation as the best. The surgeon offered one, which, were it not for its absurdity, I would not mention it: he said that C24 stood for carbon, 24 atoms; H20 for hydrogen, 20 atoms; O20 for oxygen, 20 atoms; K for kallium, or potassium; E for euphion, or wood-tar. Now the sailmaker was the only well-read man in the mess, for he had red hair and whiskers, and his hands were red also from the constant use of keel, which he stated was the same thing as kallium. So, having obtained an old edition of "Silliman's Chemistry," he pored over it, until he found, on page 445, the symbols, C34, H82, O4, and he was horrified to find that it expressed human fat. The K he found to be potash, on page 414; and he found E to mean tar. He expressed himself astonished, and the conclusion that he arrived at was that the fish of the carpenter (the carpenter was the caterer of the mess) was human fat, and that the potash got into the dish at the galley-fire, and the tar from the boatswain's hands; then, in a furious passion, he pronounced the boatswain and carpenter as bloody-minded cannibals, and then left the mess in disgust, as he said that he was not fond of human flesh; he might eat cats and dogs, but would have nothing to do with their C, H, O, K, E; he wished he might be blessed if he did.

I once heard the boatswain telling the first lieutenant about the main buntlines; he said that they rove through a shoe-block. I asked him if a last had a hole in it. He replied, "What last are you asking about?" I replied, "that he had just told the first lieutenant that the buntlines were rove through a double block at the masthead, then through the shoe-block, and again through the double block, and that the last was split; I suppose that you meant the shoe-block, as it is the last where I came from. But your grammar was bad if you meant the shoe-block, as the last block you mentioned was the double block." His reply showed that his education had not been neglected with respect to shoes, for he said, "Curse your last and sole too; I'm no shoemaker." But his very language betrayed him to be such. The boatswain uses me very disrespectfully; he never calls me by my proper name; he always calls me Bob Stay; he had better keep his tongue.—I remain, respectfully, your obedient servant, ROBERT STAY, Reefer, U.S.N.

THE PORTRAITS OF SIR ISAAC NEWTON.

ABOUT a year and a-half since, Doctor Crompton read a paper before the Literary and Philosophical Society upon the portraits of Sir Isaac Newton. The Doctor recently informed the Society that while preparing his essay for publication, he had opened up fresh sources of information, and became possessed of facts of considerable interest respecting the portraits of Newton. He had examined about twenty portraits of the great philosopher, all of which were considered to be originals, and most of which were undoubtedly painted a long time ago; but he had seen no portrait which, in his opinion, was of equal importance and interest with the Kneller Newton of 1689, to which he last year directed the attention of the Society, as by far the most valuable portrait of the great philosopher in existence, and of which he exhibited an admirable engraving by Mr. Oldham Barlow. His extended inquiries into the subject of the portraits of Newton had led him to the conclusion that there are several (if not many) which pass current as portraits of him which are most decidedly representations of other persons. In the National Portrait Exhibition at Kensington of the present year there were four portraits of Newton, two of which he feels sure have no real claim to be regarded as authentic or genuine. These two are pictures contributed by the Earl of Dartrey and by the Marquis of Exeter. The former purports to be a portrait of Newton when he was a Bachelor of Arts, and to be painted by Lely. It represents a young man with his hand resting on a globe; and there is an engraving of the picture, done many years back, but he had no hesitation in saying that the picture had no right to be considered a portrait of Newton. The features were not Newton's, and it was most improbable that the poor Trinity College Sizar would, when a Bachelor of Arts (that is, between January, 1665, and July 7, 1668), have cared, or, if he had cared, could have had the means to obtain a portrait of himself. He apprehended that because the portrait represented a young man with his hand on a globe, some imaginative person had supposed that it must be a representation of the great philosopher who had explained the system of the universe. But this portrait represents one of the poorest specimens of humanity; and certainly not a Newton, but rather a Simple Simon.

The Marquis of Exeter's picture has hardly any greater claim to be regarded as a Newton. It represented a man with a bald head, but there was the clearest evidence that Newton was not bald.* The two Vanderbank portraits representing him the year before his death without his wig, show that he had a beautiful head of silver white hair. There is another portrait of Newton by Thornhill, taken at an earlier period, which represents him without his wig, but with short white hair and no trace of baldness. The Portsmouth Kneller of 1689, which represents him when he was forty-seven years old, shows him without a wig and with abundant grey hair. This is a sufficient ground for rejecting this picture; but no one who has studied the portraits of Newton could be brought to believe that this is a representation of the great philosopher. Last year, when reading his paper, Doctor Crompton remarked that he had been unable to discover where the original Kneller of Newton, engraved by Houbraken, was to be found. He then pointed out that in some impressions of the Houbraken print it was stated to be in the possession of Mr. Conduit. Dr. Crompton went to the Earl of Portsmouth's seat at Hurstbourne Park, and there found the original picture. It is dated 1702, and signed by Kneller. The Earl of Portsmouth, Newton's collateral descendant, therefore possesses the two most important portraits of Newton. This portrait of Newton was engraved also by Smith, about 1712.

A replica, if not an early copy, without any name of an artist upon it, is in possession of the Duke of Devonshire, at Holkar. His grace informed the Doctor that he could not positively trace its coming into the possession of his family, but he conjectured that it might have been at Holkar before the marriage of one of the Lowthers with Lady Mary Cavendish, through whom this Holkar property passed to the Cavendishes. There is an exact replica or early copy of the Portsmouth Kneller of 1689 at Lord Galway's, except in not having the name of Newton or of Kneller upon it, which Dr. Crompton has examined, and which, in an old catalogue of the pictures, is said to be painted by Bond. Dr. Crompton said that he had examined the three oil paintings of Newton in the Royal Society's collection; also the Kneller at Hampton Court, which is dated 1689, and differs from the Portsmouth Kneller of 1689 only in the position of the hands; also all the portraits of Newton belonging to Trinity College, Cambridge; the Indian ink drawing of Newton in the Pepysian Library at Magdalen College; and a portrait at Mrs. Miles', at Firbeck Hall, Yorkshire, which resembles very much the Egremont Newton by Kneller, engraved as a frontispiece to Sir David Brewster's first "Life of Newton," published in the "Family Library." Dr. Crompton exhibited this edition of Brewster's life, as well as the larger one in two vols. In the text of both the engravings, which differ very greatly from each other, are said to be from a picture in the possession of Lord Egremont. Sir David Brewster was unable to explain how it was that two engravings from distinct and different portraits should thus happen to be spoken of in the text, except that his publisher must have selected the second portrait and got it engraved. It is, the Doctor thinks, unmistakably taken from Smith's print of 1712 or an early impression of Houbraken's engraving. The portrait prefixed to the small "Life of Newton" is the same as that engraved in Lodge's portraits. At present, Dr. Crompton is unacquainted with the historical evidence regarding the genuineness of this portrait. It is signed by Knoller, and dated 1716; but Dr. Crompton has not yet seen it, nor one in the possession of Mr. Turner, of Stoke Ashford, near Grantham.

In Lord Portsmouth's collection at Hurstbourne, besides three genuine and authentic portraits of Newton, there is a fourth picture with the name of Newton painted upon it. It was described to Dr. Crompton by a gentleman who had had an opportunity of a very close examination of it, as the earliest and most important portrait of the great philosopher. But Dr. Crompton found neither date nor artist's name upon it, and the picture, which is mounted upon panel, has a crest in red wax behind it, which is not the crest of the Ports-

* Mr. Conduit, Newton's nephew by marriage, when describing Newton's personal appearance, says, "With a fine head of hair as white as silver, without any baldness, and when his peruke was off, was a venerable sight."—Brewster's "Life of Newton," 1855, vol. ii., p. 413.

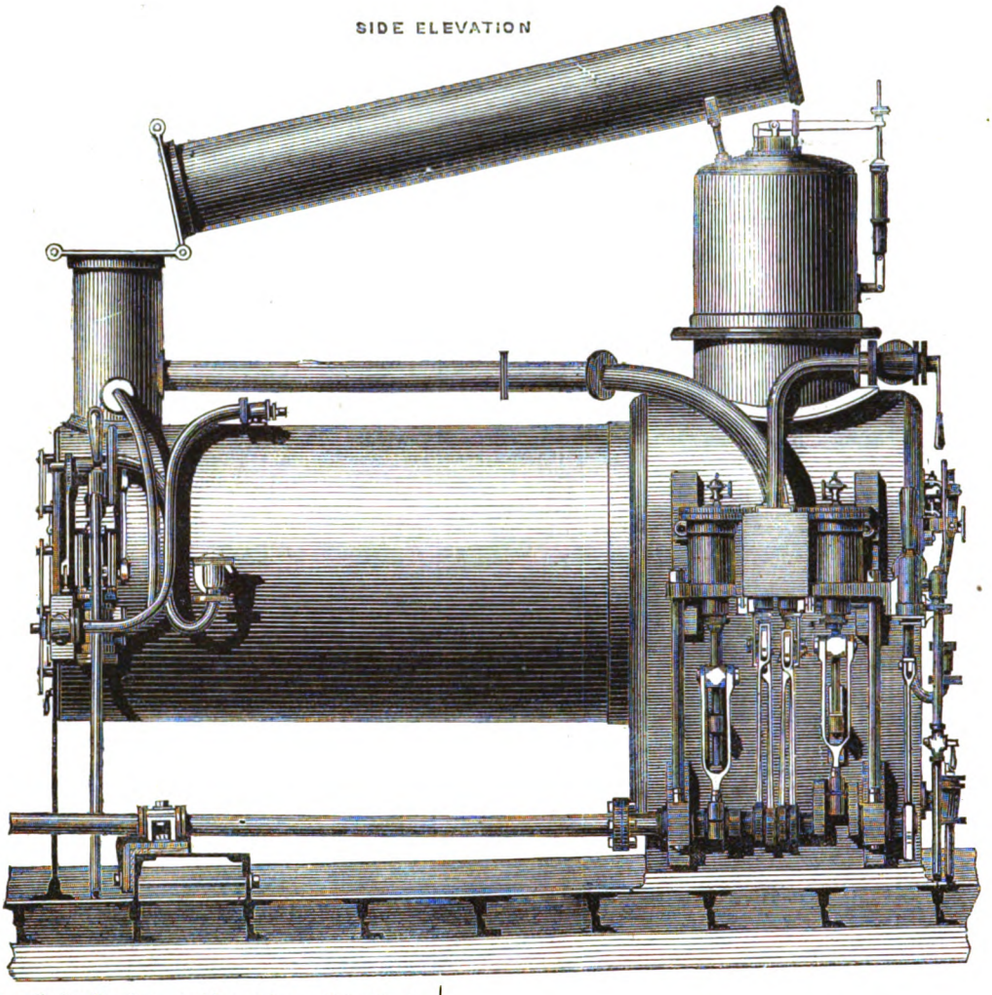
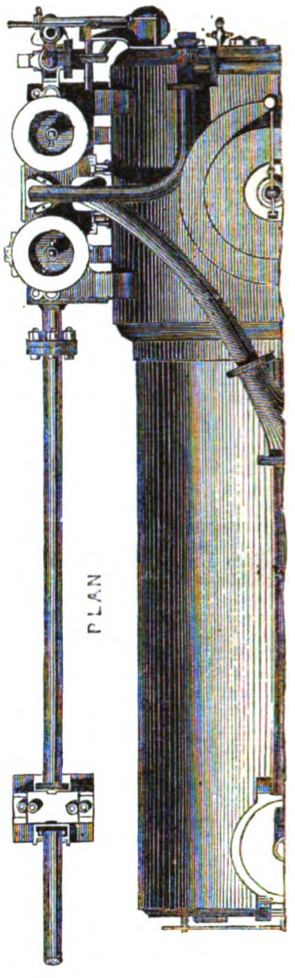
ENGINES OF THE "GREAT EASTERN'S" STEAM LAUNCH.

BY MESSRS. FORRESTER AND CO.

SIDE ELEVATION





mouth family, but could not be sufficiently determined what it was for want of a magnifying glass. The history of this picture will be investigated further; though it is certain that it cannot be a portrait of Newton, for the features are not his, and the eyes are brown, while Newton's were bluish grey. It is most earnestly to be desired that all the portraits of Newton might be collected together at Kensington for comparison with each other, and that the portraits of other great men (where there are several) should be thus exhibited in juxtaposition. It would probably then be evident that there exist many spurious ones, and an opportunity would be thus afforded of determining which are the best as well as the true.

ENGINES OF THE "GREAT EASTERN'S" STEAM LAUNCH.

THE above illustrations represent the engines of the steel steam launch which was built and engined for the "Great Eastern" by Messrs. Forrester and Co., of Liverpool. The boiler is of the locomotive type, the barrel being 2ft. 6in. in diameter and 5ft. long, including the smokebox. The front of the boiler is fitted with two firedoors, for the purpose of insuring the least amount of air passing into the firebox during the operation of stoking; the door below admits air to the grate. The bottom blow-out cocks and pipes are at each side of the doors, and the surface blow-off cock directly over the upper door, and on each side of the cock are the gauge cocks and glasses. The boiler, it will be noticed, is stayed longitudinally by six stays suitably disposed. The firebox is fitted with a dome 16in. in diameter and 2ft. high, and contains a trap to prevent the water, when priming occurs, from entering the steam pipes leading to the cylinders. Two safety valves are attached to the dome, each being compressed by a spring to a maximum pressure of 60lb. on the square inch. The length of the firegrate is 2ft., and the width 2ft. 6in.; the tubes are fifty-one in number, each being 4ft. long and $1\frac{3}{4}$in. external

END ELEVATION

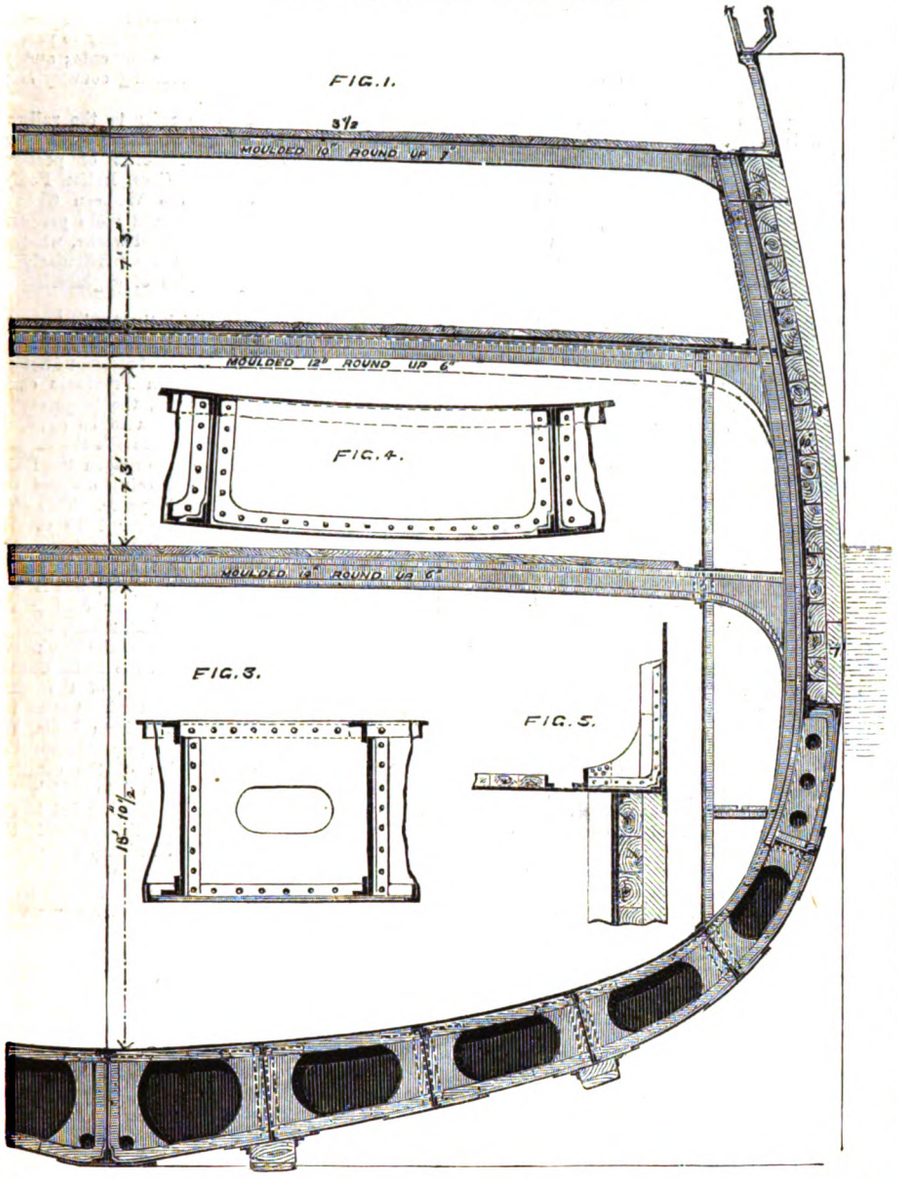
THE IRON CLAD FRIGATE "WILHELM I."

DESIGNED BY MR. E. J. REED.



diameter. The proportions of the heating surfaces are—grate, 5 square feet; firebox, 20 square feet; and the tubes, 93 square feet. The diameter of the chimney is 9in., and the height from the smokebox 7ft.

The engines are of the direct-acting type. The cylinders, each 5in. in diameter, with a 6-inch stroke of piston, are secured to the boiler at the firebox end by wrought-iron brackets, the latter being placed there after being riveted to the boilers. The slide valves are single ported, having a lap of 5-16in., and the width of the opening attained in the cylinder ports for the admission of the steam is ¼in., the width of the supply ports being 7-16in. The steam cocks are attached to the dome, and the starting gear is at the boiler front. The connecting rods, each 15¼in. between centres, are forked, the piston rods being 1in. in diameter, and guided by eye brackets below the connecting pin. The slide valves are between the cylinders; the link motion and eccentrics are, therefore, between the inner cranks. The crank shaft is supported beyond each outer crank by the capped ends of the wrought-iron columns, the upper ends of which are fixed to the cylinders, and the lower ends bolted to the firebox. Near the smokebox end of the boiler is the thrust block, of the ordinary kind, secured by bolts, nuts, and caps. The thrust of the screw is resisted by the foot of the block being secured at right angles to the line of strain. Each pair of engines is fitted with a feed pump, worked by an eccentric on the extremity of the shaft, the stroke of the plunger being 2¾in., and the diameter 1⅜in. A donkey engine is also supplied, fixed to the side of the smokebox. The steam cylinder is 3in. in diameter, and the plunger of the pump 1½in.; the length of the stroke being 3in.; the donkey can also be worked by hand. The screw propellers are four-bladed, 3ft. diameter; pitch, 3ft. 6in. The propeller, shafts, and tubes are of gun-metal, and gun-metal bosses are riveted in with the plates of the launch for supporting the inner ends of the stern tubes, the outer ends being supported by wrought-iron brackets close to the bosses of the screws. The hull and frames are built entirely of steel; the length is 50ft., with a beam of 10ft. In the above engines Messrs. Forrester have supplied a good example of marine engineering on a small scale.

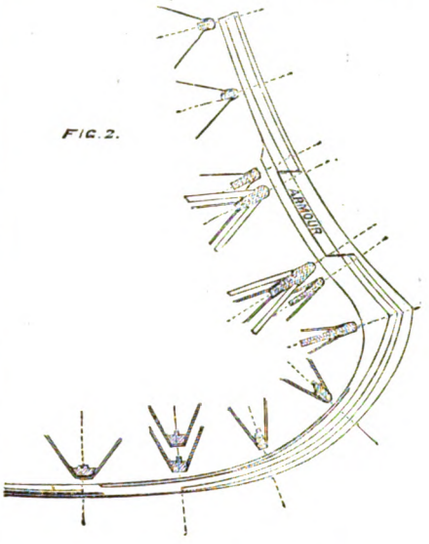
THE IRON-CLAD FRIGATE "WILHELM I."

IN our issue of the 31st of January last we promised our readers a detailed description of the iron-clad frigate "Wilhelm I.," now building by the Thames Ironworks Company for the Prussian Government, and we now fulfil that promise. The ship was originally designed for the Turkish Government, at the request of the Sultan, and with the sanction of the Lords of the Admiralty, by Mr. E. J. Reed, Chief Constructor of the Navy. She was, however, as we previously stated, subsequently purchased by the Prussian Government. The construction of the ship will be clearly understood by the following description, with the aid of the accompanying engravings. The principal dimensions of this fine frigate are as follows:—

	Feet	in.
Length between perpendiculars ...	355	10
„ of keel for tonnage	310	1⅛
Breadth, extreme	60	0
„ for tonnage.....	60	0
Depth in hold	18	10½

Burthen in tons, O.M., 5,938 71-94ths.

The vessel is built of iron, with a ram bow, and a protected battery extending for a length of 232ft. on the main deck, in which she can fight 28 7-ton guns, with the port sills 10ft. above the water. At the stern on the main deck she has a 7-ton gun protected by armour, and which can fire right astern in a line with the keel. There is an armour-plated bulkhead at the fore end of the battery extending right across the ship, and from the lower deck through the upper deck to the forecastle, protecting two 7-ton guns on the upper deck. Each of these guns can be worked at two ports, so as to fire right ahead and 20deg. abaft the beam. The armour-plated bulkhead at the after end of the battery is cut off by the upper deck, but two half towers, one on each side of the ship, are built for protecting two 7-ton guns; each of these guns work at two ports, from one of which the guns can be fired at an angle of 15deg. with the keel, and from the other at 30deg. forward training. The half towers project beyond the ship's side about 4ft., which does away with the necessity of "hancing" the ship's side. The guns forward fire over the upper deck, there being no topsides above it to interfere with them. The hull of the ship is protected by the armour, &c., on the sides of the battery, the armour extending from 6ft. 8in. below the water up to the upper



deck, the lower strake being 7in., and all the others 8in. thick, tapering to 5in. and 6in. at the extremities of the ship. The armour forward of the battery only extends to the lower deck, which is about 2ft. above the water, very strongly built, and plated over with 2in. iron; abaft the battery the armour extends to the main deck and right aft up to the upper deck to protect the gun. The ship has a single screw and balanced rudder, which is well protected at its head by the armour on the stern. The draught of water forward is 24ft. 6in. and 26ft. 6in. aft. The engines, which are being constructed by Messrs. Maudslay, Sons, and Field, are of 1,150 nominal horse-power, and capable of working up to six times that power, and calculated to drive the vessel at a speed of from 14½ to 15 knots per hour. She is to be ship rigged, and fitted with three iron lower masts, with steel topmasts and yards, and her bowsprit is fitted for running in when used as a ram. The men will be berthed on the main deck inside the battery, and the officers on the same deck, but abaft, in the unprotected part of the vessel.

She is constructed with an inner skin extending about two-thirds the length of the ship, and up to the main deck on each side. The space between the two skins is divided longitudinally by the vertical watertight keel, and by two watertight longitudinal frames, one on each side at the foot of the wing passage bulkhead, and transversely about every 20ft., giving great safety in case of the outer skin being pierced, as the water could only fill the compartment injured. Before and abaft this inner bottom the ship is formed into sections by horizontal watertight iron flats and transverse frames, with watertight trunks extending up to

Digitized by Google

the main deck, conducing greatly to the safety of the ship. The method of construction is shown in fig. 1. The keel is formed of two flat keel plates, the inner one 1in. and the outer one 1¼in. thick, of a vertical keel plate 54in. deep and ⅞in. thick, extending from the stem to the sternpost, and firmly secured to them; it is connected to the flat keel plates by double continuous angle irons 6in. × 6in. × 1in., and on its upper edge short angle irons are worked between the frames, the whole well caulked and making a watertight longitudinal division through the double bottom. The stem and sternpost are solid forgings, to which the vertical flat keel plates and continuous angle irons are scarphed. The construction of the stem will be clearly seen from the profile view and sections given in fig. 2; it is a solid forging sufficiently large for the armour, backing, plating behind armour, and the two thicknesses of outside plating forward to rabbet into and fasten to it. All these plates being butted square in the stem form strong supports to it in case of the vessel being used as a ram.

The longitudinal frames, of which there are six on each side of the keel, in this ship extend right forward to the stem; they are formed of plates varying in depth from 22in. to 46in., of continuous angle irons on their outer edges, and short angle irons on their inner edges; before and abaft the double bottom the longitudinals are reduced in depth, and the angle irons on their inner edges are also continuous; the three longitudinals out from the keel are tightened by holes taken out of them (see fig. 4) so as not to reduce their sectional strength. No. 3 longitudinal, forming the foot of the wing passage bulkhead, is made watertight throughout the double bottom; the upper or No. 1 longitudinal forms the recess for armour and backing; the longitudinals and the continuous angle irons are well butt strapped, and they are worked on outside strakes of plating, care being taken that they shall not cross the joint, and their surfaces are twisted so as to always stand square to the section of the ship. The transverse frames in double bottom are 4ft. apart, and are composed, as shown in fig. 1, of continuous angle irons on the inner edges, which extend across the keel, and are scarphed to the frames behind the armour of short angle irons on their outer edges to which the outside plating is riveted, and of bracket plates which, with short angle irons on the longitudinals, are all riveted together. At every 20ft. solid plates are substituted for the bracket plates, made watertight with staple angle iron (see fig. 4) and with the keel, and No. 3 longitudinal, dividing the double bottom into watertight compartments; before and abaft the double bottom the transverse frames are made of plates, tightened, instead of bracket plates. Between the recess plate and No. 2 longitudinal, plates with holes to tighten them are worked, the better to sustain the immense weight of armour. The transverse frames behind the armour are 2ft. apart, formed of angle iron 10in. × 3½in. × ½in., with double angle irons on its outer edge 3½in. × 3½in. × ⅝in.; of these frames every alternate one is scarphed at each side of the longitudinal at the foot of the wing passage, to the continuous angle irons before alluded to, the intermediate ones being ended at this longitudinal. The framing above the armour is formed of plates 7in. × 7-16in. with a single angle iron on the outer edge 4in. × 3½in. × 9-16in.; these frames are worked directly over the alternate frames behind the armour, being 4ft. apart, and formed, as shown in fig. 5; between these intermediate frames, with feet riveted to the deck plating, are worked.

The outside bottom plating is worked, as shown in fig. 1, with alternate raised and sunken strakes; the edges are double, and the butts treble chain riveted. The plating varies from 1in. to ¾in. Forward it is doubled and rabbeted into the stem, and aft the plates are 1in. thick and chased into each other, forming a flush surface. The plating above the armour is ½in. thick, flush jointed, with edge strips and butt straps on the inside. Behind the armour two thicknesses of plating, each ¾in. thick, are worked, the inner having butt straps, and the outer edge strips. The joints of the outer thickness are arranged to take the fastenings of the longitudinals, of which there are two to each strake of armour. Thus the target forming the ship's side is made up of armour 8in. thick, 10in. teak backing, longitudinal girders, two thicknesses of ¾in. plating, and frames 2ft. apart, composed of an angle iron, 10in. × 3½in. × ½in, and two of 3½in. × 3½in. × ⅝in. The upper deck is formed of Butterly beams 10in. deep, spaced 4ft. apart, entirely covered with ½in. steel plates for the length of the battery, before and abaft it with steel plates ½in. thick, the whole being covered with 3½in. Dantzic deals. The main deck is formed of Butterly beams 12in. deep, one at each frame. The entire surface abaft the battery, the deck within the battery from about 7ft. out of the middle line to the sides, and before the battery, is covered with ½in. iron, worked as well as on the upper deck, to the outside plating, and secured with staple angle irons, the whole being covered with 4in. Dantzic oak.

The lower deck, the foreside of the battery, in consequence of the armour not running above it, and being very near the water, is very strongly built. It is formed of beams 10in. deep, filled in solid between with teak, and covered with plating 2in. thick. From the foremost bulkhead of the battery to the stern the beams are 14in. deep, formed of plates and angle irons, upon which is worked a stringer plate running through the wing passage bulkhead, and forming the lower side of a gutter. Forward it is scarphed to the 2in. plating, and the whole is covered with Dantzic deals 3½in. thick. The decks are firmly supported by hollow pillars, with solid heads and heels, those in the hold being 7in. diameter and ½in. thick. There are nine transverse watertight bulkheads, enclosing engine and boiler rooms, magazines, double bottom, &c., built of ½in. plates, with angle and T-iron stiffeners. The ship is well ventilated, drained, and fitted with sluice valves to all watertight compartments. The vessel is now fast approaching completion, and will be a most formidable ship of war.

SOCIETY OF ENGINEERS.

(Continued from page 221).

THE general substitutes for piles in India are well or block foundations, which have been in use for very many years; they are peculiarly adapted to the deep sandy beds of Indian rivers, and are extensively used, both for bridges and buildings. A foundation may consist of a number of wells, sunk close together, and connected together afterwards; or, what is better, of a block or blocks of masonry made to the required shape, and having holes left of the same size as the wells; the latter, however, requires experienced workmen, and circular wells are, therefore, generally used. In both cases the method employed is the same. A wooden curb of hard wood, and of a thickness varying from 6in. to 18in., is made of the size of the well or block, and fixed in position on the river bed. On this about 4ft. in height of masonry is built; and, when dry, the sand inside is scooped out, so that the curb and masonry descend. Another 4ft. is then built, and again the same process is resorted to, and the curb again made to descend until any required depth is attained.

As long as the water in the interior can be kept out by pumping or lifting, the work proceeds quickly; but when the work has to proceed under water, it is very slow. A machine called a jham is used. This is, in fact, a huge hoe, with a straight socket cast on to it, to receive a pole, by which the jham, when lowered into the water, can be worked into the sand from a stage above. The pole is then withdrawn, and, by means of a windlass and rope, the jham, with its load of sand, is dragged up, emptied, and again sent down. In some parts of the country the well-sinkers dive every time, and work the jham into the sand by their hands; and divers have generally to be employed in case of any obstruction to the regular descent of the well. The wells or blocks are either driven down to the solid clay or rock, or they may be suspended, as it were, in the sand by mere friction. In Madras, when the wells are used to carry bridge piers, it is usual only to sink them about 6ft. in the sand, the piers being connected together both at their up and down stream ends by a line of wells, acting as curtain walls, to prevent a scour; a flooring of masonry or concrete is also added between the piers. The wells being finished, may be filled in with loose brick or kunkur, arched over, and connected together by arches, on the top of which the superstructure is built, or they may be filled with concrete from the bottom, thus forming a series of solid cylinders.

Since the establishment of roads, river communications have, in some sense, diminished in their importance, and the number of native boats is not so numerous as formerly. But with the introduction of steamers many rivers have required improvement, in order to render their channels free from obstructions. For this purpose river conservancy establishments are maintained, whose duties are to keep the river channels clear from sunken boats, and from trunks of trees which are often brought down by the monsoon rains, and fixing themselves in the bed of the river, obstruct navigation. In other rivers natural obstacles have to be overcome, as in the Godavery, in the course of which river three extensive barriers of rock obstruct the navigation in different parts of its course. In some cases it is necessary to protect the banks from the action of the currents; and in others to protect the surrounding country from inundations during freshes.

It is not intended here to refer to the railway system of India, on several of whose lines there are, however, to be found works of peculiar interest, especially where the Great Indian Peninsula Railway passes over the Western Ghauts. These, and such like works, would more properly come under the heading of special works, whereas the object of this paper is more particularly to describe the general principles of engineering in India.

Following the order in which the ancient works of native origin have been dealt with, the irrigation works of modern construction next command notice.

Soon after the North-Western Provinces came under the British Government, the propriety of restoring the Mogul canals began to be agitated. Attention, it is said, was first drawn to the subject by the offer of a Mr. Mercer to reopen the Delhi Canal at his own expense, on being secured the whole proceeds of it for twenty years. This offer was declined; and about the year 1810 several officers were deputed to survey and report upon the lines both east and west of the Jumna. The subject was, however, soon dropped; but it was resumed with characteristic vigour during the administration of the Marquis of Hastings, who, in 1817, appointed Lieutenant Blane, of the Engineers, to superintend the restoration of the Delhi Canal; and, in 1822, Lieutenant Debude, of the same corps, was ordered to survey and report upon the Doab Canal. Similarly, in Southern India, the works of the natives were followed up and improved upon soon after the acquisition of the country. The hopeless state of confusion into which the Tanjore Government had fallen having led to the cession of the country to the English, in 1801, the maintenance of the works of irrigation of course developed upon them from that time forward; and it was not long before certain defects, inherent to the system, began to exhibit themselves in a very clear and unpleasant manner.

The earlier works of this character, undertaken by the British in India, were, almost without exception, the restoration of ancient native works, and the defects originally existing in their construction were too often followed and imitated. On the Ganges Canal, for the first time, there was new ground to work upon, and Sir Proby Cautley and his able assistants successfully overcame the difficulties attending that vast project.

There are two distinct systems of canal irrigation carried out in India; that in the north differing in many respects from the plan pursued in the south, in consequence of the physical peculiarities of the two parts of the country. The southern, or Madras, system, which is confined chiefly to the deltas of the great rivers, such as the Godavery, Kistnah, &c., consists in throwing a dam, or anicut, across the bed of the river, to raise the surface level of the water, which is then conducted along canals, whose mouths are above the dams, to the lands requiring it. This system is necessarily confined to alluvial tracts which have been formed by deposits from rivers in a state of flood.

In the rivers of Northern India, although there is a certain width of low alluvial land on either side, it is only a narrow strip. The greater portion of the country consists of a high table land, occupying nearly the whole extent of the Doab, and in general rising very abruptly from the khadir, or low-lying land. In this case it is necessary to go back to a point high up in the river's course, whence the water can be brought on to the high land by excavation of a moderate depth, and by which sufficient command of level may be obtained to overflow the surface. For this purpose the water is generally, in Upper India, taken from the rivers, where they emerge from the mountains.

The simplest kinds of canals used in Upper India are those which are generally known as inundation canals, of which there are many existing along the borders of the Punjab rivers, by which the khadir, or low land, is irrigated. Cuts are made from the river inland, for a certain distance, and are then carried in a direction generally parallel to the fall of the country, or the course of the river. By these, when the latter is in flood, the autumn crop is watered; but in the cold season, when the river is low, the canals run dry, and

Digitized by Google

the spring crop thus derives no benefit from them. During that time of year, therefore, labourers are employed to clear the canals of the silt which was left by the waters in their beds, or heaped up at their mouths. There are no works at the head of such canals to control the supply of water, for the course of the river is so uncertain, that it may completely desert the head, and the water may have to be brought in by a new mouth excavated for that season, which again may be useless in the next.

It would be impossible, without exceeding the limits to which a single paper should extend, to enter into the many details of construction of each class of work to which allusion has here been made. It is proposed, therefore, to conclude the present paper with a short statement of the expenditure incurred in India for public works, and the establishment by means of which such works are undertaken.

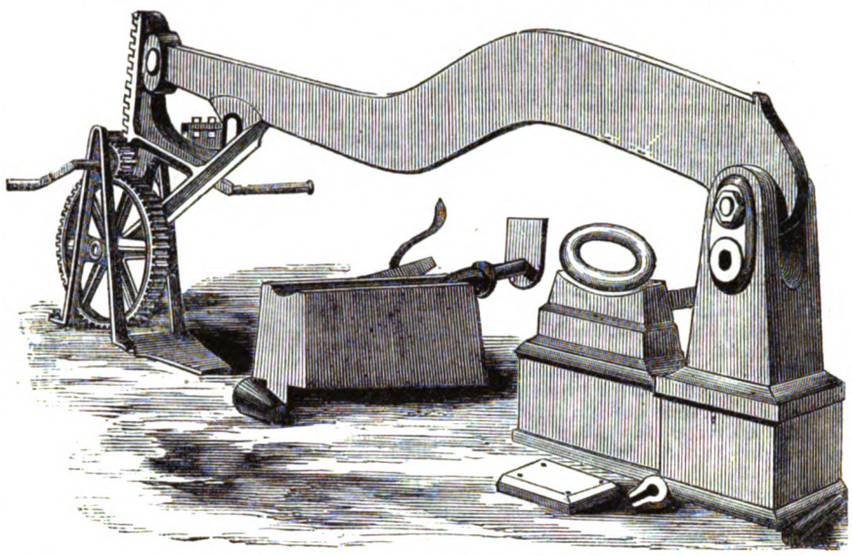
Notwithstanding what has been stated relative to the construction of a certain class of public works by the native rulers in former ages, it does not appear that any spirit of enterprise exists amongst the natives of the present day, and consequently the construction of remunerative works is but to a very limited extent promoted by means of private speculation: and with very few exceptions, the public works of the country are carried out through Government agency. The funds for this purpose are provided from the surplus revenues of the State, and the receipts from remunerative works are credited to the same account. Prior to the year 1853-54, the construction of public works devolved upon different departments, according to the character of the works executed, and, on this account it would be somewhat difficult to state with any degree of accuracy the precise sums so expended. In 1853-54, the total expenditure amounted to £2,586,531, and with the exception of the period during which the Indian mutiny almost put a stop to all public works, the annual expenditure on their account has gone on gradually increasing. In 1863-64 the sum expended was £4,459,264, and the estimated expenditure for 1867-68 was £6,637,500. With the increase of total expenditure, the item of establishment has, as might naturally be expected, also increased. Thus in 1853-54 the the sum entered under that head was £405,506, whilst in the estimate for 1867-68 it has been set down at £1,027,700, being 15·15 per cent. on the total estimated expenditure for the whole empire.

Prior to the constitution of a regular Public Works Department, the duties of superintending public works were entrusted to agencies, varying in the different presidencies. Thus in the Bengal Presidency the Military Board had the control of all public works, but it was also responsible for the Army Commissariat and Government Studs Departments, and for the Department of Ordnance, including the foundry, the gun-carriage agency, the powder mills, the arsenals, and the military equipments of the army, with the exception of clothing. In the Madras Presidency, public works were carried on under three distinct and independent departments. 1st. The Public Works Department of the Board of Revenue, which had the control of all irrigation works, of all civil buildings in the provinces, and all roads and bridges (not included in the "Trunk Roads" or in military cantonments), and all canals, &c. 2nd. The superintendent of roads, who had the sole superintendence of the great lines of communication classed under the term "Trunk Roads." It was his duty to propose all new roads on these lines, as well as all repairs and improvements, and he and his subordinates executed the greater part of the work. And, 3rd. The Military Board, to whom was entrusted the construction and repair of fortifications; of all public buildings, both military and civil, at the presidency; the Government roads, and all bridges at the presidency; all military buildings and forts in the provinces; and roads, and bridges, &c., in military cantonments, as well as the roads, bridges, and civil buildings and works in the Saugor division. Besides, which, the work at the Paumbum Channel was under the sole superintendence of the chief engineer. And in the Bombay Presidency the control of works was vested in the Military Board and the Road and Trunk Department.

(To be continued).

THE number of visitors to the Patent Office Museum, South Kensington, for the week ending March 21, was 3,720; total number since the opening of the museum, free daily (May 12, 1858), 1,264,042.

MACHINE USED IN IRON CABLE MANUFACTURE AT GUERIGNY.



MANUFACTURE OF IRON CABLES AT GUERIGNY.

IT has often been adduced as a proof of the different *regime* existing in our own country and that of France that the majority of the large manufactories and engineering works are in the hands and under the authority of the Government. Until very recently this was unquestionably the fact, but lately private enterprise and private capital have found there that scope previously either denied them or of which they failed to avail themselves. If we look, however, into the early history of many of the imperial establishments, as they are termed, we shall find that, as a rule, they were all founded by the energy and capital of private individuals. So long as the particular branch of industry carried on did not develope itself beyond certain limits the Government took but little notice of it; but no sooner had it arrived at a sufficient degree of importance to attract the attention, and probably the jealousy, of the State than it was at once annexed by the latter power. In modern times the desired acquisition was achieved by purchase; but the Government was not always so particular and considerate in its mode of proceeding. The present imperial establishment at Ruelle was seized, barely a hundred years ago, from the original proprietor, M. Montalembert, who for sixteen years afterwards received not the slightest compensation for the unwarrantable injury inflicted on him, and at the expiration of that term his just claims were but very reluctantly recognized and very incompletely satisfied. M. de la Chaussade, the original proprietor of the premises at Guérigny, met with better treatment than the former gentleman, for about the year 1780 the French Government bought the whole concern from him at a fair valuation for £120,000, and he retired into private life at Paris, where he died some years afterwards. We shall not follow the further development of these works, or the various ways in which they were submitted successively to the control of different departments of the State, for although the history is in itself interesting, yet the actual production of the workshops is that with which we are more immediately concerned. It was not until the year 1828, according to "Les Grandes Usines," that hempen cables gave way to those of iron, and necessitated in consequence the erection at Guérigny of premises specially adapted for their construction. They were built, and the manufacture of iron cables has been conducted ever since on an increasing scale. They are capable of turning out over thirty miles of chain cable in a year, and during the continuance of the Crimean war their production was upwards of fifty miles. About twenty-five years ago the imperial cables were tested competitively with those manufactured by private firms, and evinced so decided a superiority in strength and quality that the large mercantile companies petitioned the Minister for the Navy, in whose hands the works were then, to allow them to obtain their cables from the imperial establishment. An assent to this request entailed so heavy a tax upon the resources of the works that considerable enlargements and improvements had to be carried out to meet the new demand, and at present the workshops are furnished with all the modern machinery and mechanical appliances that science can devise and money procure.

Before passing on to the description of the manufacture of the cables, we will take a glance at that of the anchors, of which it appears there are no less than ninety-six different sizes, varying in weight from 12lb. to 5 tons, and suitable for the smallest craft as well as the most powerful armour-plate afloat. Since 1835 the anchors have been forged upon what is known as the Swedish plan, by welding the arms upon the shank, thus virtually making them consist of three distinct pieces—the two arms and the common shank. One advantage of this plan has been found to be in causing the iron to act more in the direction of the fibres, and also a fewer number of heatings is required than in the processes formerly employed, and the result of too many heatings is a deterioration in the quality of the material. The method of forming the arms, together with the flukes, is deserving of attention. A large fagot of bars, of uniform thickness but of different lengths, in order to cause a break in the joints, is welded together by a 12-ton steam hammer. It is afterwards worked into the shape of a triangle, with a projecting rib in the central portion, heated to a white heat, and submitted to the action of a die having the form of the arm required to be made. A few blows with the steam hammer and the thing is done. It only remains to weld on the shank and the anchor is complete. If the employment of a first-class description of iron is of paramount importance in the production of an anchor, it is not the less indispensable to that of the cable. That in use is procured from various firms, but for some years past the works at La Haute Marne have enjoyed almost a monopoly of the supply. Any iron that may be sent to the establishment is tested gratuitously, and the sender may compete for contract, provided it stands the test satisfactorily. In the first place it must have been produced from pigs made with charcoal, and every bar must be marked with the distinguishing mark of the firm producing it. Each separate bar is subjected to a searching scrutiny before it is permitted to undergo any actual testing operation, and if a flaw is discovered it is at once rejected. Again, a certain number of bars are selected and cut half through and the appearance of the section carefully examined. To test whether the iron is sufficiently soft and calculated to resist a shock it is submitted to a series of blows from a 25lb. hammer, and its elasticity is determined as follows:—The bar is put under a powerful hydraulic press and at the moment of fracture it should exhibit an elongation of 1-1800th of its original length, and the tensile strength must not be less than twenty tons to the square inch. These are termed the cold tests, and supposing them to be successfully undergone, the hot tests are commenced, and are thus conducted:—A right-angled bend is made in the bar, it is then straightened, bent again, re-straightened, and bent a third time, and the bar must not break until the operation is repeated a fourth time. Holes having a diameter equal to three-quarters of that of the

Digitized by Google

bar are punched in it, while at a dull red heat, and no flaws or cracks must appear. To ascertain whether the iron possesses good welding properties, and that the grain suffers no injury, or the elasticity any diminution from the action of heat, a welded bar is tested by the hydraulic press, and it must give the same results as on the previous trial, When the bars have passed both the cold and fiery ordeal they are further subjected to the various processes they will have to encounter in the actual manufacture of the cables. They are tested in the shape of links, and four defective examples out of a hundred are sufficient to cause the iron to be rejected. Considering the severity of these tests it is not surprising that the iron supplied to the imperial premises costs £18 per ton.

The diameters of the cables increase by a regular difference of one-twelfth of an inch, from ¼in. to 2⅜in.; sometimes, but rarely, they reach the dimensions of 2⅞in. Bar and rod iron are both used in making the cables. They are first heated to nearly a white heat, then bent, re-heated, and cut by a blow of a hammer upon an anvil in a manner so that the two ends are bevelled off. The welding is performed by hand labour, and the workmen have a certain amount of work to get through daily. In welding the cables a small cylinder of iron called a stud is set in the link to prevent it from becoming flattened when under tension. By means of the lever represented in the cut the ring dilated by heat is compressed, and in contracting when cold it seizes the stud and fixes it immovably. It is then passed through a link previously made and the two ends welded together under the hammer. Each chain or separate portion of a cable is 100ft. in length, and is tested up to 20 tons per square inch of sectional area. After being examined link by link with respect to both their lengths and diameters, the chain is passed, and the year of its manufacture and its proper number marked on the two extreme links. A register is kept of these particulars, and also of the name of the foreman who superintended the welding, and who is still held responsible for any defect that may hereafter occur, and were it brought home to him, would lose both his place and his right to a pension.

MR. SEELEY'S PIGS.

WERE the Bank of England to announce that from this date, they would only part with the gold in their cellars at £5 per oz., the ordinary trade value being a fraction under £4, the buyers of gold would at once withdraw their custom, and the gold would remain unsold. But the true value of the gold itself would not be lessened thereby, the loss on interest falling on the Bank directors. Now such is the exact position of "Seeley's Pigs" with the Admiralty Departments at present. Their value—which has been proved—remains the same. The public property in the hands of the Storekeeper General, or rather under his feet, has been increased by Mr. Seeley's bringing them to light, and the gratitude due to him from the public should be none the less because his service is not represented by actual money. Why, asks the "Iron Trade Circular," is it not so? Why have not these pigs been sold, and who has stopped the way? Not the Lords of the Admiralty, for by them and by their Secretary every facility was afforded. Their intention was direct and honest, and they honestly carried it out to the extent of their power. Did the fault lie with Messrs. George Ryland and Co.? Certainly not. The letter of Messrs. W. Bird and Co. is a sufficient answer on that score. But it happened, unfortunately, that when the question of starting at a price arose, "My Lords" had to consult, and were bound officially to be instructed by the Storekeeper General's Department, the very office mainly responsible in the first instance for the disposal of the pigs as paving stones. This department, then, felt it their duty to put the highest value on the pigs (previously estimated by them in a minute of "My Lords" at £1 per ton, and so charged by thousands of tons to the Engineering Department), and their Lordships were informed that the pigs could not be sold under £4 per ton short weight at the dockyards. Whereupon "My Lords" insisted on the sales already effected at £3 being cancelled, and started the pigs at a fixed minimum price of £4. It was vain to show that a market had to be made. Their Lordships' reply to this was the grand flourish that the Admiralty could not speculate; that the pigs were said to be worth £5 a ton (it was useless to talk of long weight and expense of delivery), so Messrs. Ryland had no option left them in selling, but the trade had the option of not buying, and they did not buy, and so the pigs were not sold. Nothing then remained but to show to the Admiralty, if they would not sell the pigs, the advantage of keeping them for their own use This was done with infinite trouble—occasioned, however, it is but just to say, only by the obstruction and delays arising in all cases from the ordinary official forms, and the difficulty of bringing different departments into communication. However, the iron was tested at Sheerness and proved to be of very high quality and adapted for many purposes, and so reported upon. Next it had to be tried for Palliser shot, for which purpose we considered it to be as good as iron the Woolwich Arsenal Department were purchasing at from £5 to £6 per ton. As the iron would have to be proved at the arsenal by an officer, who had already, under other circumstances, reported against it, it was asked—so as to avoid placing that gentleman in an invidious position—that Messrs. Ryland might be present at the trial. This request was made three months ago, and repeated to the War Office by another application a month since, and there the matter rests after six months' attention. The merits of the navy ballast iron are unquestionable—except to the wilfully ignorant. It has been tried by the most eminent firm in Sheffield, and we doubt not, even yet, in spite of the Duke of Somerset, to see it in the armour plates of some future "Hercules," or on a Gibraltar target, stoutly resisting the indent of Palliser shot, also of its own formation. We hold the same opinion as we first expressed; the navy ballast iron in her Majesty's dockyards, laid down as flooring, used instead of paving stones, stuck up as side walls (and none the worse for it, be it said), is of the best quality of iron now to be had in England, fit, with judicious admixture (as required by other pig iron), for all naval and engineering purposes, and capable of being converted, at small expense, into the best steel. On a rough estimate we should say there is full £200,000 worth of it lying about, and this amount, or something approaching to it, ought to be carried to the credit of "Stores," and so be gradually run off into use, and the interest on so large a sum saved to the nation.

A NOVEL GUNBOAT.

A GUNBOAT named the "Staunch," built for the Admiralty upon the proposition and plans of Mr. George Rendel, of the firm of Sir William Armstrong and Company, has just been completed, and tried at sea off the mouth of the Tyne, with the Admiralty inspectors and a numerous party of officers on board, including some members of the Ordnance Select Committee. A correspondent of the "Pall Mall Gazette" gives the following account of the boat:—This vessel, though wholly insignificant in appearance and cost, represents some very novel principles. She is only 79ft. long and 25ft. beam; her draught of water when loaded 6ft., and her displacement 150 tons. She has twin screws driven by two pairs of condensing engines of 25-horse power (nominal) combined, giving her a mean speed of seven and a-half knots. She carries as heavy a rifled gun as any in the navy, and to all appearance carries it most efficiently. The gun, a 12½-ton 9-inch Armstrong, is mounted in the fore part of the boat in a line with the keel, and fires through a bulwark or screen over the bow, which is cut down and plated something like that of a Monitor. Thus placed, it is easily worked in a rolling sea, and its change of position by recoil does not appreciably affect the trim of the vessel. At the same time, to provide for heavy weather, it is made capable of being lowered into the hold, so as to relieve the little vessel of its deck load, and enable it to carry the weight as cargo. Machinery is also employed for the purpose of working the gun, by which means more than half of the ordinary gun's crew can be dispensed with. The operation of lifting and lowering is performed by simple but powerful machinery. During the recent trials, the gun, with its carriage and slide, and the platform carrying them—weighing in all twenty-two tons—was raised and lowered in a rough sea, with the boat rolling 11deg. each way, in from six to eight minutes. When the gun is lowered the gun-well is closed and the deck left perfectly clear, but in a few minutes the gun can be again brought up ready for action. For working the gun small capstan heads on deck are used. These are turned by machinery from below, and instead of the gun tackles being hauled by a large gun detachment, one man on each side has merely to take a turn with his rope round the nearest of the revolving capstan heads. The capstan, upon his tightening his end of the rope, draws the rope for him, and on his slackening his end frees it. Thus the gun is run in or out, or trained right or left, with great ease and precision. In the same way shells are run up out of the shell room, and other analogous services performed. This simple method of economizing manual labour has been already applied in many ways, such as for drawing trucks and moving heavy weights in railway goods stations, in conjunction with hydraulic machinery. With such assistance, during the trials of the "Staunch," the 12½-ton gun was easily handled by six men, instead of sixteen, and fired with extra charges of 56½lb. of powder, and 285lb. shot. It must be observed that very little, if any, training is requisite with the gun of the "Staunch." The vessel is so small as to be a sort of floating gun carriage. Her twin screws enable her to turn rapidly in her own length. Her helmsman is placed just behind the gun. The gun, therefore, can be laid by rudder right or left with far more ease and speed than any gun of similar weight otherwise mounted. During the recent trials with the engines driving reverse ways, the vessel made the full circle in her own length in 2¾min. With both engines going full ahead, she made by the helm a complete circle of seventy-five yards diameter in 2½min. The "Staunch" is wholly unarmoured. Her strength and security lie in her great gun and her diminutiveness. And she must be considered as one of a flotilla of similar vessels. Sixty such could be built at the price of a single armour-clad frigate, and ten of them, acting from different points, doubling in their own length, escaping into shallows, sheltering under forts, would drive off, or render a good account of any hostile vessel venturing to attack our harbours. Primarily they are intended for harbour defence; but the power of lowering the gun and carrying it as cargo would afford great security for these vessels at sea, and enable them to be sent from harbour to harbour with safety. The "Staunch" is now to be sent round to Portsmouth, where she is to be attached as experimental gunboat to the gunnery ship "Excellent."

CAST-STEEL BOILERS.

THE use of steel in the manufacture of steam boilers is of comparatively recent date, and the relative advantages, if any, over ordinary iron boilers, except on the score of their less weight, has hardly yet been satisfactorily determined. We, "Scientific American," have before us perhaps the latest information bearing on this subject, being the results of an important series of experiments made recently at the rolling mills of Messrs. Funk and Elbers, of Hagan, Prussia, for the purpose of ascertaining the respective evaporating power of the new compared with the old style of boiler.

The two boilers experimented with were each 5ft. in diameter, and 34ft. long, constructed to stand five atmospheres "over" pressure. One was made of wrought iron, and the other of soft cast steel. The thickness of the sides in the cylindrical portions of the iron boiler was 0·50 of an inch, and of the cast-steel boiler 0·33 of an inch. Each boiler had a heating surface of 293 square feet, and 12 square feet of surface. Both were new, and had never been before heated. They were set alike in brickwork, one above the other, but entirely separated by masonry; the gaseous products of combustion passed through a single flue underneath each boiler, and passed directly into the same chimney. At first both boilers were filled, and fires were kept under them for several days in order to dry the brickwork, after which the fires were extinguished and the boilers emptied and cleaned. Each boiler then received exactly 712 cubic feet of water at 95deg. Fah. temperature; the man-holes were closed, and the water was heated to the boiling point; again the fires were put out, and all the ashes and coals taken away. From this point the boilers were fired afresh, and fed with weighed fuel; the man-holes, hitherto kept closed, were now opened to let the steam escape; and the firing was so well regulated, by means of dampers, that the velocity of the escaping steam—measured by List's velocimeter—was the same in each boiler. The temperature of the gases from the fire was measured, at a point 6ft. from the rear end of each boiler, by Gauntlett's pyrometer, and found to vary from 644deg. to 734deg. Fah.

After consuming on each grate 3,150lb. of coal of the same quality, the cinders of which were burned over and over again, the fires were put out, and the man-holes closed. On the following day the remaining water of the boilers, showing a temperature of 95deg., was let out through the emptying tube, situated at the lowest part of the boiler, and measured by means of a hydrometer adapted to the tube. The iron boiler showed 387 cubic feet, and the steel boiler 331 cubic feet of the remaining feed water. Therefore the water evaporated in the iron boiler was 712—387—325 cubic feet, or 20,065lb.; and that evaporated in the steel boiler was 712—331—381 cubic feet, or 23,523lb. Hence the evaporating capacity was proved to be 17·20 per cent. in favour of the steel boiler. 1lb. of coal evaporated in the iron boiler 6,350lb. of water, and the steel boiler 7,367lb. of water at 212deg. Fah.

At the next trial the whole operation was performed in the same manner, only the velocity of the escaping steam was less. It resulted in showing 19·62 per cent. in favour of the steel boiler. 1lb. of coal evaporated in the iron boiler 5.809lb., and in the steel boiler 7,008lb. of water. These two experiments were verified in the following manner: To an equal quantity of feed water in each boiler an equal volume of a strong solution of salt was added. After stirring the water for some time, by means of long poles, and boiling it with closed man-holes, samples were taken out for future analysis. In completing this experiment, in which equal quantities of fuel and water were used, further samples were taken out. The analysis of the samples by Dr. List, of Hagan, showed that in the iron boiler one quart of water contained before evaporation 4,629 grammes of

Digitized by Google

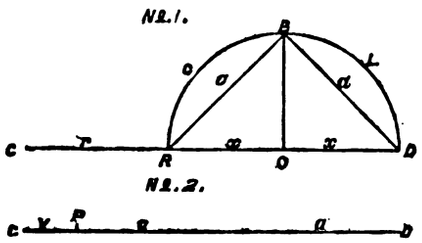
chloride of sodium, and after, 5,985; in the steel boiler one quart contained 4,871 grammes before, and 7,885 grammes of salt after evaporation; the iron boiler lost 33·76 quarts, and the steel boiler 40·81 quarts of water, showing 20·85 per cent. in favour of the latter. The average per centage of these three experiments is 19·24 per cent. in favour of the steel boiler, which, it will be noted, had a shell 33 per cent. thinner than that of the wrought-iron boiler.

Correspondence.

SQUARING THE CIRCLE.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—Will you allow one, who is not the least a mathematician, to submit to the many readers of the MECHANICS MAGAZINE a definite expression for the relation of the circumference to the diameter of the circle? If the diameter be 1, I have found the circumference to be precisely $\frac{20\sqrt{2}}{9}$. This result I have obtained in the following manner:—Let the



line C D (No. 1) be supposed to be equal in length to the semicircle described on R D. On the diameter of the semicircle construct the triangle R B D. Drop B O perpendicular on R D, then B O is equal to R O and to O D. Let each side of the triangle R B D be represented by a, and R O and O D each by an x. Let the line produced from D R to C be represented by r. On another line equal to C D (No. 2), let P D be equal to R B, and B D = $2a$, and the remainder of the line by v. Finally, let C D be equal to 10, and the semicircle R G L D also is equal to 10. From this it can be shown that v is equal to 1, and that $2x$—the diameter of the circle—is equal to $\frac{9}{\sqrt{2}}$, the exact diameter of a circle whose circumference is 20. This makes the measure of a circle, whose diameter is 1, to be $\frac{20\sqrt{2}}{9}$, or 3·1423611, &c.; the figure 1 continually recurring. This is a little in excess of the recognized measure, and very nearly that adopted by Archimedes.—I am, Sir, yours, &c., J. STAPLETON.

George-street, Plymouth.

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith.—ED. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

RECEIVED.—J. H.—G. L.—R. S.—G. G.—H. N.—W. T. R.—J. H.—W. J. M.—H. P. S.—J. S.—L. P.—T. H. S.—T. C.—Messrs. M. R. and Co.—F. N. S.—R. I.—G. W. H.—T. B. J.—S. M.—H. S.—J. H.—A. W.—T. H.—J. N.—W. J. M.—T. B.—H. D. R.—G. W. H.—B. B.—J. F.—W. H. H.

Meetings for the Week.

MON.—Royal United Service Institution.—1st. Mr. James D. Dougall on "Schultze's Granulated Wood Gunpowder;" 2nd. Mr. George Read, R.N., "Will Explain a Model of his Helm Indicator," at 8.30 p.m.

Society of Engineers.—Special General Meeting for Consideration of Proposed Alterations in, and Additions to, the Rules and Bye Laws of the Society, at 7.30 p.m.

TUES.—The Institution of Civil Engineers.—Mr. John Wolfe Barry, M.I.C.E., on "The City Terminus Extension of the Charing Cross Railway," at 8 p.m.

Royal Institution.—Dr. M. Foster on "The Development of Animals," at 3 p.m.

WED.—Society of Arts.—Mr. Raphael Brandon on "How to Make Railways Remunerative to the Shareholders, Beneficial to the Public, and Profitable to the State," at 8 p.m.

THURS. — Royal Institution.—Dr. M. Foster on "The Development of Animals," at 3 p.m.

FRI.—Royal Institution.—Professor Frankland on "The Proposed Water Supply for the Metropolis," at 8 p.m.

SAT.—Royal Institution.—Professor Roscoe on "The Non-Metallic Elements," at 3 p.m.

Naval, Military, and Gunnery Items.

THE total number of vessels at present composing the navy of the United States is stated to be 230, with an aggregate of 140,746 tons burden, and 1,915 guns.

FROM Prussia we learn that Herr Pauer, the well-known but hitherto unsuccessful inventor of submarine ships, has constructed a new model, which looks promising enough to have obtained the honour of a special federal commission to test its merits.

A SERIOUSLY destructive fire recently broke out in the Chassepot rifle manufactory belonging to Messrs. Reeves, George-street, Birmingham. The premises, which were very compact, were partially burned down, and the damage done to machinery and stock is estimated at £5,000.

AN order has been received at the Royal Engineer establishment, Chatham, directing a party of non-commissioned officers to proceed to Persia to join the detachment of sappers of the Royal Engineers engaged in laying down the telegraph overland to India, under the superintendence of Major Smith.

IN addition to the "Sultan," the new iron-clad of the "Hercules" class ordered to be laid down at Chatham dockyard, a powerful turret armour-clad ship, to be named the "Triumph," is directed by an Admiralty order, just received, to be constructed at that establishment, the designs for both vessels having been prepared at the Admiralty, where the drawings and plans are now being made.

THE "Ringdove," first-class gun vessel, 666 tons, 160-horse power, has just made an official trial of her speed at the measured mile, Stokes Bay. Six runs were made at full boiler power, the result being a mean speed of 10·632. Four runs were made at half-boiler power, the mean speed being 8·145. The engines worked well, indicating a maximum of about 900-horse power. The speed attained cannot be regarded as very satisfactory. The "Ringdove" was designed by Mr. E. J. Reed, and built at Portsmouth.

IT is stated that the camp of Chalons this year will be composed as follows:—First division of infantry, 1st brigade, 3rd battalion of Foot Chasseurs, and 5th and 8th of the Line; 2nd, the 13th and 18th of the same arm. Second division, 1st brigade, 9th battalion of Foot Chasseurs, 29th and 67th of the Line; 2nd, the 44th and 78th regiments. Third division, 1st brigade, the 18th Foot Chasseurs, 65th and 67th of the Line; 2nd, the 81st and 92nd of the same. Cavalry division, 1st brigade, 5th and 6th Lancers; 2nd, the 3rd and 9th regiments of Dragoons.

THE attention of shipbuilders, engineers, and others interested in the shipping trade is called to the fact that the time for applying for space in the Havre Maritime International Exhibition is drawing to a close. As the Board of Trade, Admiralty, and other public departments have set the example, it is hoped that a good display will be made of all that relates to the great maritime interests of the country. The concessionnaires, Messrs. J. M. Johnson and Sons, of Castle-street, Holborn, are prepared to receive applications for space until the 15th proximo.

THE shipping employed in our coasting trade in 1867, the total of entries inwards and clearances outwards with cargoes, amounted to 285,918 vessels of 36,854,343 tons. Only 1,090 vessels of 194,168 tons were foreign. The number of vessels decreases, but the tonnage (except in 1867) increases. The total tonnage was 35,009,528 in 1864, 36,325,219 in 1865, 37,005,575 in 1866. The decrease in 1867 is in that part of our coasting trade which does not consist in intercourse with Ireland; in the intercourse with Ireland the number of vessels engaged and the amount of tonnage increase year by year, without exception.

Miscellanea.

AN avalanche five or six miles in extent occurred near the town of Cisco, California, on the Pacific Railroad recently. Six Chinamen were killed and seven locomotives were injured.

IT is announced that the Prince of Wales has signified to the committee of the National Exhibition of Works of Art, at Leeds, that he will open the Exhibition in the week commencing Monday, the 18th of May.

A COMPLAINT in Chancery has been lodged against the Anglo-American Telegraph Company by Mr. W. P. Piggott and others, for a suspected infringement of Mr. Piggott's patent for improvements in the mode of generating electric currents.

A PAMPHLET about to be published by M. Horn states that the expenses of the French Empire from 1852 to 1866 (both inclusive), amounted to the terrific sum of 31 milliards of francs, or £1,240,000,000 sterling.

THE Right Hon. W. E. Gladstone, M.P., has consented to preside over the Statistical Section at the approaching meeting of the British Association for the Advancement of Science. The meeting will be held at Norwich, in August next.

LIVERPOOL is making every exertion to induce the Royal Agricultural Society to hold its annual gathering for 1868 in that town. A meeting was lately held in the Mayor's parlour, and a committee was elected to form a guarantee fund of £3,000.

WE understand that the Benchers of the Honourable Society of the Middle Temple are preparing for publication a "History of the Temple," with a succinct account of the most eminent of its *alumni*. The record will extend over a period of between three and four centuries.

THE "Siecle" tells us that the Director-in-Chief of the French Telegraphs has decided that each of his servants shall wear a uniform—which is quite necessary—and also carry a sword, with a brass pommel and scabbard. "All the world," adds the "Siecle," "is asking what they have to do with that weapon."

THE vast area of the metal portion of the roof of the New-street Railway Station, at Birmingham, is now being recovered with Vieille Montagne zinc. The zinc used is 16-gauge, and more than 100,000 square feet will be required to complete the work. The old roof of corrugated galvanized iron has been thoroughly worn out during thirteen years.

WE are happy to state that the honorary office of president of the Horological Institute of Great Britain, rendered vacant by the death of Mr. Valentine Knight, J.P., has been accepted by Mr. E. B. Denison, Q.C. We congratulate the members of the Institute on the acquirement of a president so distinguished as a horologist and as a man of science.

AT the South Kensington Museum the visitors during the week ending March 21, were:—On Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 10,968; on Wednesday, Thurday, and Friday (admission 6d.), from 10 a.m. till 5 p.m., 1,697; total, 12,665. Average of corresponding week in former years, 10,773. Total from the opening of the museum, 7,255,358.

WE have much pleasure in announcing that Sir Roderick Murchison has been elected by the Academy of Sciences in Paris Foreign Member, in place of the late Professor Faraday. There are only eight such members, and the honour is regarded by men of science as the highest which a man of science can receive. As a matter of form the decision has to be submitted to the Emperor for his confirmation.

IN the competitive trials for drawing, conducted by the Science and Art Department, South Kensington, 588 schools contended. When the awards were made the greatest number appeared for the Orphan Working School, Haverstock-hill. This establishment entered the lists for the first time, and sent up 161 boys, 71 of whom had their drawings marked excellent, 39 were adjudged proficient, 39 were considered fair, and 12 passed over.

IN connection with the construction of railways in Russia, it is important to note that the lines opened for traffic realized last year a notable progress in their receipts as compared with 1866. In the case of the Moscow and Riazan this progress was 51 per cent., in the case of the Volga and Don 39 per cent., and in the case of the Riga and Dunaburg 30 per cent. The last enterprise, it will be remembered, was to some extent an English work.

A COMPANY has just been formed at Naples for coal mining in the Neapolitan provinces, and, in consequence of experiments that have been made at the naval arsenal, the Government has ordered 50 tons, which are to be supplied from the mines of Giffoni, Valle Piana, in the Principato Citeriore. The experiments that have been made with this coal at Naples, prove that it is of excellent quality, and most suitable for gas manufacture.

IT appears, by the "Journal de Frankfort," that a statue of Napolean the First, by Canova, which stood in the Salle des Etats in the time of Jerome, king of Westphalia, has been found hidden in a barn in the garrison of Cassel. Unfortunately, at the time of the retreat from Moscow, the statue was removed and mutilated, the arms, it is said, having been sawn off. The French consul has applied to the Prussian authorities for the statue in question.

A DEPUTATION from the British Association for the Advancement of Science lately had an interview with the Premier, to urge upon her Majesty's Government that, in the event of the Natural History Collections in the British Museum being moved from their present site in Great Russell-street, the administration of these collections should be intrusted to a director immediately responsible to some Minister of the Crown, and that the authority of the present trustees over them should cease.

THE value of the telegraphic wire and apparatus exported from the United Kingdom last year was £209,688 as compared with £312,288 in 1866, and £148,679 in 1865. In the ten years ending 1867 inclusive, the value of this branch of our exports will be seen to have been very considerable, viz., in 1858, £224,708; in 1859, £742,806;

Digitized by Google

in 1860, £251,712; in 1861, £214,441; in 1862; £320,897; in 1863, £317,214; in 1864, £218,464; in 1865, £148,679; in 1866, £312,288; and in 1867, £209,688.

THE steam force of the Metropolitan Fire Brigade has just been increased by three new steam fire-engines of Messrs. Merryweather and Sons, long-stroke single-cylinder pattern. The success of these makers at the Paris Exhibition has caused the Metropolitan Board of Works to choose these engines. One of them is the engine "Le Prince Imperial," which gained the gold medal at Paris. They have steam cylinders, each 6½in. diameter, and double-acting pumps each 5½in. diameter, with 18in. stroke of pistons.

THE arrangement of the third and final collection of national portraits is now making good progress at South Kensington. There is no want of portraits; indeed, the great difficulty is to find space for those already received. The exhibition will consist of portraits of eminent persons who have lived during the present century, and of many distinguished people who flourished prior to that time, forming a supplement to the whole series. In all, there will be about 900 portraits, and efforts are being made to open the exhibition on Easter Monday.

THE yield of gold from the mines of Victoria for the year 1867 was 1,493,831 ounces. The average number of miners employed was 65,857, and the average earnings 35s. per week. The gold mining companies in the colonies paid in the year 1867 dividends amounting to more than £820,000, being a much larger number of pounds sterling than the number of the entire population—men, women, and children. The amount would be very largely increased if there were added the profits of private mining undertakings, and of companies which do not make public their yield and dividends.

STEPS are being taken for the formation of an Archæological Society for Birmingham and the neighbourhood, in connection with the Birmingham and Midland Institute, for the examination, study, and preservation of local antiquities. A committee has been formed to make the necessary arrangements with the council of the institute for carrying out the project. Members of the institute, on paying 5s. a year, are to become members of the archæological section. Donations are to be requested towards a copying fund for providing drawings and photographs of old documents and old buildings, and for preserving old relics of the history of Birmingham and its neighbourhood.

DURING the last week three stone axes, which have been found by drainers in the alluvial clays of the Derwent and the Rye, have been purchased by Mr. C. Monkman, of Malton. Mr. C. Hartley has also purchased one found in a similar way. The axes are met with at depths varying from 2ft. to 3ft. 6in. A pierced stone hammer was found a few days ago, and, with the flint axe found at Norton a few weeks ago, make up six weapons which have been discovered during the winter months, all of which, except that above-named, have passed into Mr. Monkman's hands. Three out of the six are very good specimens. From the same beds the Rev. J. Robertson, of Appleton, has obtained some very fine flint arrow heads and implements during the past draining season. It is believed that many stone antiquities have been destroyed in the Ryedale district, simply from ignorance of their value by the workmen.

IT has long been a contested point with collectors as to what kind of china really was made at the first manufactory of this ware in England, which is known to have been established at Bow in 1744, and what mark served to distinguish it from that of other manufactories. In trenching for a drain at the lucifer-match works of Messrs. Bell and Black, at Bow, an important piece of evidence has fortunately been turned up. The cutting has intersected a waste heap, and many fragments have been found, consisting of knife handles, cups, and plaster moulds for casting the ornaments in relief. The curator of the Geological Museum in Jermyn-street has thus been enabled to identify as of Bow manufacture two perfect specimens in the ceramic collection of that museum, and Mr. Bell has liberally given several of the fragments to the museum. It should be added that no distinguishing mark has as yet been found on any of the specimens.

MR. BARKER, organ builder, Paris (inventor of the pneumatic lever), has just patented in France and England a complete system for applying electricity to supersede the ordinary mechanical key and draw-stop action in large organs. The patentee has already built a grand electric organ of forty-two sounding stops and eight couplers for St. Augustin's, Paris, and another for Salon, near Marseilles. As the largest organs may now be played through a cable of insulated wires, positions hitherto wholly impracticable can be turned to account. The organist, with his various claviers, can be placed in any direction, and at any distance away from the organ, the touch being equally delicate and rapid on every manual, whether used separately or coupled. Bryceson Brothers and Co. have the concession for working this patent in Great Britain, either as regards new organs, or applying the electric action to existing instruments.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

BOILERS AND FURNACES—2425, 2430, 2472
BUILDINGS AND BUILDING MATERIALS—2481, 2486
CHEMISTRY AND PHOTOGRAPHY—2437, 2449, 2458, 2501
CULTIVATION OF THE SOIL, including agricultural implements and machines—2427, 2462
ELECTRICAL APPARATUS—2480
FIBROUS FABRICS, including machinery for treating fibre, pulp, paper, &c.—2439, 2442, 2445, 2446, 2448, 2460, 2490
FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—None.
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c—2455, 2496
GENERAL MACHINERY—2428, 2432, 2433, 2441, 2451, 2454, 2468, 2470, 2487, 2493, 2497, 2498, 2500
LIGHTING, HEATING, AND VENTILATING—2435, 2461, 2491
METALS, including apparatus for their manufacture—2438, 2463, 2484

ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—2434, 2465, 2482, 2483, 2485, 2499.
SHIPS AND BOATS, including their fittings—2440, 2443, 2467, 2469, 2473, 2476
STEAM ENGINES—2456
WARFARE—2431, 2477, 2488

2425 A. and E. WIGZELL. *Improvements in, or applicable to Juckes' furnace.* Dated August 24, 1867.

The patentee claims, first, the application to Juckes' furnaces of tumbling gratebars, or bars hinged at one end only, on portable rods supported and carried by endless chains. Second, the general arrangement and combination of parts of apparatus, substantially as described and illustrated in the drawings.—Patent completed.

2426 J. P. SMITH. *An improved mode of, and apparatus for, hauling, draining, and other agricultural implements in the field by steam power, and also an improved truck for mounting and carrying such implements from place to place.* Dated August 24, 1867.

According to this invention the implement is to be attached to a block carrying a pulley round which the rope passes, the other end of the said rope being brought back again and fastened to the wheel or other stationary part of the engine, or to any other firm anchorage. The object of this contrivance is to reduce by one-half the speed at which the implement travels, and hence to gain an equivalent increase in the power. The block to which the pulley is attached is mounted upon a cranked or other axle carried by two wheels or rollers, so as to allow it to accommodate the angle of the flanges of the pulley to the direction in which the rope pulls. The improved truck consists of a body or framework composed of wrought iron, or other suitable material, with the bottom about the same distance from the ground as the lowest part of the traction engine, and having two running wheels either mounted on cranked axles passing under the body, or on short axles affixed to the sides of the truck. The lower part or front of the truck is cut away to admit of a steering wheel, the shelf thus formed in the inside of the truck serving to carry a vice and a portable forge, and the back of the truck, or the lower part thereof, is made to fall down on hinges so as to form an inclined plane up which the implements are easily moved into the truck. The inside of the body of the truck is furnished with two longitudinal angle irons or projections about midway of its height to receive the ends of boards for forming a second flooring if required. The front of the truck is provided with a draw bar and shackle for attaching the traction engine thereto.—Patent abandoned.

2428 M. SAMUELSON. *Improvements in sewing machines.* Dated August 24, 1867.

This invention relates to the general construction and arrangement of what are known as shuttle or lock stitch sewing machines, and consists of the following arrangement:—The cloth plate is screwed on to brackets cast on a bed plate, which brackets carry a transverse driving shaft provided with a small hand pulley, and with a duplex cam for imparting a to and fro and up and down motion to a serrated feeder, the feeder being of the description known as the under "four motion feed." To one extremity of this driving shaft there is keyed a disc provided with a crank pin which works in a differential slot in the end of a vibrating lever working beneath the cloth plate, and secured to a rocking shaft working between adjustable screw centres in brackets cast on the bed plate at the back end thereof. To the opposite end of the driving shaft there is keyed another disc carrying a crank pin for the purpose of driving the shuttle, as hereinafter explained. The rocking shaft above referred to derives its motion from the first-mentioned crank pin and differential slot in the lever arm attached to such shaft, and this vibrating motion is imparted to the needle arm, which is also secured to the rocking shaft, the needle being curved and attached by a pinching screw, or otherwise, direct to the end of the lever. The shuttle is carried in a box or chamber formed on the upper end of a vertical lever situate below the cloth plate, and in place of reciprocating in a straight guiding groove or race, as in most of the reciprocating shuttle machines heretofore constructed, it describes an oval or elliptical course in front of a smooth face plate. The shuttle lever is attached at its lower end to a sliding block working between vertical guides secured to or cast on the end plate, and at an intermediate point between the sliding block and the shuttle box the shuttle lever is connected by a crank pin with the disc hereinbefore referred to for actuating the shuttle. As this pin revolves, it imparts not only a vertical but also a lateral movement to the shuttle lever, the combination of which two movements produces the elliptical or oval course of the shuttle. A small catch is fitted to one end of the shuttle box for affording facility for the introduction and removal of the shuttle. The presser foot is carried in the end of a fixed overhanging bracket arm, and is held down by a spring and elevated by a cam lever attached to the end of the arm, such cam acting upon the enlarged head of the stem of the presser foot.—Patent abandoned.

2429 W. E. NEWTON. *An improved fastening for paper bags and paper parcels.* (A communication.) Dated August 24, 1867.

This invention consists in applying to the open or mouth ends of paper bags, and also to sheets of paper designed for wrapping purposes, a thin sheet metal strip, over which the edge of the paper is secured, so that the filled bag, or the sheet after being rolled or folded, will enclose the article within it, and may, by bending over the metal band, be securely fastened without the aid of strings or tapes, or any mucilage or adhesive substance whatever.—Patent completed.

2430 H. DAVEY and D. DAVY. *Improvements in apparatus for supplying or feeding water to steam boilers and other vessels.* Dated August 24, 1867.

Here the inventors mount a wheel with recesses on its circumference, or openings in its side, on centres or spindles in a casing, so as to turn freely. This casing is provided with two openings, one communicating with the boiler below the water level, and the other with the steam space. It is further provided with one or more openings for receiving the water from a tank or other supply. These openings are arranged on the circumference at the sides, so that as the wheel revolves, the recesses or openings being previously filled, the steam becomes filled with water on passing the supply openings from the tank (the steam being condensed), and thence pass round to the openings communicating with the boiler, where they are emptied of water and again filled with steam. The apparatus is made self-acting by arranging the inlets for the water, so that it impinges in an inclined direction on the wheel cavities, causing it to start in the required direction, the motion being further maintained by the weight of water being on one side of the wheel only.—Patent abandoned.

2431 W. R. LAKE. *Improvements in cartridges for breech-loading firearms.* (A communication.) Dated August 24, 1867.

This invention relates to means for holding the priming or fulminate in the proper position to be ignited by a blow received on the base of the cartridge shell or case, and also to the means for strengthening the said base and preventing the access of gas to the rim. The improvements consist, chiefly, in the employment of a metal cup of peculiar formation which is placed in the rear of the cartridge shell; also in the novel construction of the base of the shell, and in the combination of the same with the metallic cup. The base of this cup is placed in contact with the interior of the base of the cartridge shell, its sides or circular portion being made to fit closely to the interior surface of the cylindrical portion of the shell. The base of the cup is formed with a recess to receive the priming or fulminate, and the recess communicates through a small hole or perforation with the charge in the body of the shell. The base of the shell is formed with a projection which fits the recess or chamber in the base of the cup, and which is forced into contact with the priming, to ignite the same when the exterior of the cartridge case is struck by the firing pin or other striking device of a fire-arm.—Patent completed.

2432 P. KNIAGHININSKY, P. GALAHOFF, and N. OSSIPOFF. *Improvements in machinery for setting up and distributing printing types.* Dated August 24, 1867.

Here the patentees arrange the types to be set up in two cases or trays having longitudinal grooves in them. The types are placed in these grooves, each letter or sort of type in its own groove. The trays are inclined so that the types slip down to the front ends of their grooves, where they are retained by pincers or lips at the mouths of the grooves. Extending along the front of these cases or trays is a plate which receives a rapid oscillating movement to and from the cases or trays. Along this plate an instrument, which they call the "collector," is able to slide; it has a nut upon it with which a screw of rapid pitch works. By turning the screw one way or the other the collector can be traversed in either direction along the oscillating plate, and so it may be brought in front of any type groove from which it is desired to take a type. The collector has a projecting beak, and when the collector is brought forward up to the type cases or trays by the oscillation of the plate which carries it, the beak seizes a type in the groove opposite to it, and removes it as the collector recedes. When the screw is next turned, the collector is brought opposite the composing stick. The composing stick is double, and has two grooves in it to take alternate lines of type; each is fitted at its mouth with pincers somewhat different from those at the ends of the type cases or trays; they are so formed that, when the beak of the collector moves up to them, they take from it the type it carries. The composing stick is between the two type cases or trays. By the repetition of these movements the types are rapidly taken from the cases or trays in the order required, and are deposited in the composing stick. The screw is driven by two electro-magnetic coils, one at each end of it, which, by driving bands, are kept constantly rotating in opposite directions. There are armatures on the ends of the screw, and when electricity is passing in either of the revolving coils, it seizes the screw and carries it round with it. So, by connecting one or other of the coils with a battery, the screw may be driven either way, and it remains stationary when no current is passing in either coil. The due regulation of the electricity to these coils will thus cause the types to be collected and arranged in the order required.—Patent completed.

2433 F. J. CLEAVER. *Improvements in screw presses and apparatus for pressing and moulding soap, or for pressing, moulding, packing, or stamping other materials.* Dated August 24, 1867.

Here the patentee connects the upper end of the axis of the screw of a press by a joint to the lower end of a piston rod, the piston of which works in a cylinder

Digitized by Google

mounted upon the framing, the piston being actuated either by steam, compressed air, or other elastic fluid. A cross head upon the piston rod gives motion to a slide valve so arranged that the length of stroke of the piston may be readily adjusted from time to time by a screw or otherwise, as required. Another slide valve is also arranged capable of adjustment, so as to cut off the steam or other motor during the up-stroke of the piston when the press is used for pressing and moulding soap, &c., where the rebound is sufficient to effect the upward movement of the piston. A flywheel is mounted upon the axis of the screw, a portion of its length being formed square, and so as to move up and down freely through a square opening in the boss or centre of the flywheel, which is retained in position by a grooved collar or otherwise. Below the plunger of the press a rotating table is arranged, upon which the moulds or dies are mounted for receivfng the soap, &c., to be pressed or moulded. A step-by-step movement is communicated to the rotating table so as to bring each mould in succession as the table rotates correctly under the plunger each time it descends. —Patent completed.

2434 W. BERRY. *Improvements in removing mud, drift, or other rubbish from streets and other places.* Dated August 24, 1867.

This invention consists, first, in using an inclined plane and receiver mounted on a frame on one or more wheels, slides, or other means; the lower end of the inclined plane is to be near the ground, so that mud, drift, dust, &c., may be swept up into the receiver, and afterwards emptied into the cart or other receptacle by a weighted lever or other means. Second, an inclined plane and receiver may be attached to the cart or other receptacle by pivots, &c., so that the contents may be readily emptied into the cart or other receptacle.—Patent completed.

2435 W. C. THURGAR. *Improvements in apparatus for regulating the supply of gas to burners.* Dated August 26, 1867.

This apparatus is actuated by clockwork which is wound up once a week, or at other convenient intervals of time. The clockwork drives a spindle which turns once an hour. This spindle has one tooth on its end, which tooth acts upon one tooth of a 24-cogged wheel which it gears with. This 24-cogged wheel has a spindle through its centre of suitable length, and fixed on the top of this spindle is a plate which has two arms, one of which is fixed while the other is adjustable for increasing or diminishing the distance of the two arms, according to the time of gear, the plate being marked to show the position to which the adjustable arm should be moved. This plate revolves horizontally once in twenty-four hours, and as it revolves one of the arms presses one side of a cam, of which there are two fixed on one end of the tap which runs through the vertical gas pipe; the tap has a small groove round the perforation, so that the gas gets through a little in daytime. When the cam is acted upon, it turns the tap so as to lower the flame, and when the other arm comes round, it comes against another part of the same cam, so as to turn the gas on full. The small blue flame which burns in the daytime is protected from the air by a guard which is pressed up by one cam in the morning, and again lowered by the arm coming against the other cam in the evening. This guard is a globe which has perforations at the bottom to let air in; the globe has a tube fixed at the bottom, and on the other end of the tube is a small plate, by pressure on which one of the cams (being fixed to the tap) lifts up the guard to shield the small blue flame in the daytime. The guard tube fits over the gas pipe.—Patent completed.

2436 E. SONSTADT. *Improvements in the treatment of seaweed for obtaining valuable products from it.* Dated August 26, 1867.

Here the patentee makes a stack of timber built in alternate layers, or in concentric layers, with seaweed, which may be wet or dry. An opening in the middle of the pile is left as a chimney into which lighted fuel may be introduced. The chimney should be closed soon after firing. He makes the covering of fresh or wet seaweed, and fires the pile, adding more wet seaweed to the covering from time to time, as may be found necessary to effect the carbonization of the interior. The process is conducted somewhat after the manner, and with the usual precautions, taken in making wood charcoal in piles. But it is advisable to place, in building the stack, iron tubes or other channels, horizontally, near the floor of the stack, penetrating to the interior timber, and projecting externally. These channels can be opened or closed at pleasure, and give control over the progress of the carbonization. He carries on the operation by preference on a cemented or waterproof and fireproof floor, provided with a trough or other means for the collection of the drainage.—Patent completed.

2437 W. R. LAKE. *A new green colour.* (A communication.) Dated August 26, 1867.

This invention consists, principally, in the employment of linseed oil, acid, and oxide of copper. It is produced by precipitating a neutral soap prepared from linseed oil with a dilute solution of copper, or in letting linseed acid act on oxide of copper, or a combination, consisting partly of oxide of copper. Oleic acids produced from other oils also furnish the said colour in divers shades.—Patent abandoned.

2438 G. HASELTINE. *Improvements in the manufacture of iron and steel.* (A communication.) Dated August 27, 1867

An extension of time for completing this patent having been petitioned for, the documents relating to the invention cannot at present be seen.

2439 W. MUIR. *Improvements in machinery or apparatus for stitching or ornamenting and uniting fabrics.* Dated August 27, 1867.

This invention is not described apart from the drawings. —Patent completed.

2440 J. W. WEBB. *Improvements in reefing topsails from the deck.* Dated August 27, 1867.

This invention is not described apart from the drawings. —Patent completed.

2441 W. E. GEDGE. *An improved machine termed a crusher, intended to divide break, or crush all substances capable of being triturated, more especially bones and horny substances of every kind, for converting them into manure.* (A communication.) Dated August 27, 1867.

This machine is composed of two cast-iron plates, the one fixed and the other movable. Each plate carries a cast iron or steel crown strongly fitted to it by four iron bolts, each crown being furnished with quadrangular and conical teeth arranged with precision, and in such wise that those of the upper plate set or take very exactly into those of the lower place, and *vice versa*. The movable or running plate, which works at a speed of about 700 revolutions a minute, is beneath, and the upper or fixed plate is strongly secured to two wooden cross pieces by four bolts. The running plate is fixed by a wedge to a vertical iron shaft, which also passes through the fixed plate to maintain it in perfect harmony with the running plate, and prevent deviation, which would inevitably lead to the immediate breakage of the machine. On the upper or fixed plate between the crown and the axle an opening is made provided with a hopper by which the substance to be treated is introduced, so that it falls perpendicularly on the running plate, which, in its rotation, throws and divides the substance between the crowns.—Patent abandoned.

2442 E. B. BIGELOW. *Improvements in jacquard power looms, and in apparatus for driving looms.* Dated August 27, 1867.

This invention comprises, among other features, the following:—One of the objects of the invention is to facilitate the operation and adjustment of the jacquard harness. The first part relates to a mode of moving the trap boards and journals to raise and depress the harness to form the shed, and is particularly applicable to jacquard looms in which the harness is counterpoised. The next part relates to a mode of raising and depressing the jacquard machine to adjust the height of the harness as it distends or contracts by atmospheric or other causes. Another part relates to a mode of operating the cylinder or polygon which carries the pattern card in jacquard looms. The object of another part of the invention is to diminish the amount of shafting heretofore required for driving looms, and to lessen the expense for belts used therefor. The detailed description of the arrangements employed for performing the invention is too voluminous to be produced here.—Patent abandoned.

2443 J. A. A. ETAIX. *Improvements in hand screw propellers.* Dated August 27, 1867.

This invention consists of the following arrangement by which the screw propeller of a boat can be put in motion without the use of steam, or of any other force than the hand. For this purpose the screw is fixed to the end of a horizontal shaft provided with a gearing on which catch the teeth of a cogwheel turned by a vertical shaft to which a flywheel has been added, and which is put in motion by a crank. This crank is either horizontal, to be turned by a man sitting, or vertical to be turned by a man standing. But the essential feature of the invention is the addition of a flywheel to the vertical shaft, which flywheel permits the increase of the revolutions of the screw. The size of this flywheel is proportionate to the space allowed and to the required motive power.—Patent abandoned.

2444 M. A. SOUL. *Improvements in fastening iron bands on bales, and in fasteners or ties for that purpose, and also in levers or implements to be used therewith for effecting the fastening.* (A communication.) Dated August 27, 1867.

This invention consists in making the ties or fasteners of such an improved construction and shape that they admit of the instantaneous application of a peculiarly shaped lever (which is used much in the manner of a button hook) for bringing together the ties which are fitted one to each end of the band.—Patent abandoned.

2445 T. SAGAR and T. RICHMOND. *Improvements in looms for weaving.* Dated August 28, 1867.

This invention has reference to the "letting-off" motion of looms, and relates to a former patent, dated July 4, 1866 (No. 1732). The present improvements consist in dispensing with the catches and ratchet wheels described in the specification of the former patent, and in using in lieu thereof the following parts:—To the axle of the usual vibrator the inventors fix a toothed segment or lever with a stud or studs; the teeth of this segment, or the studs of the lever, take into the teeth of a wheel on the boss of which is a pinion gearing into a wheel on the axle of the warp beam. When the tension of the warp depresses the vibrator, the tooth of the segment or the stud of the lever is raised, and allows one tooth of the wheel in which it gears to slip, thereby letting off a portion of the warp. The parts remain in these positions until the tension of the warp depressing the vibrator again allows another tooth to slip, and thus the warp is let off as required. The second part of the invention consists in tightening the warp when the reed is beating up the weft by an eccentric on the crank shaft acting on a lever to which the vibrator is connected; or by connecting the lay sword or the lay to a lever loose on the axle of the vibrator, in the upper arm of which lever is a set screw against which the vibrator presses when the reed beats up.—Patent abandoned.

2446 H. HANSON. *Improvements in machinery or apparatus employed for finishing cotton, band, twine, ropes, cordage, and other fibrous substances.* Dated August 28, 1867.

This invention relates to a former patent, dated December 31, 1857 (No. 3195). The inventor employs, instead of the ordinary walk, a rail or tramway of any desired form or length, and places upon it a travelling frame or carriage supported by any suitable number of wheels, and capable of being drawn from one end to the other, both ways, either by hand or by drums and ropes driven by power. The top of the frame or carriage forms the table for supporting the material to be sized and finished, and also holds the size, &c., employed, and the present invention consists of improved means of giving the to-and-fro motion to the travelling carriage. Instead of employing two drums and two ropes, and allowing the ropes to be wound on and off the drums alternately, he employs an endless rope or band passing over pulleys and through guides and a locking box in the carriage, the top of the rope always passing in one direction, and the bottom part of the rope in the reverse direction when the machine is at work. The rope passes in a groove of a double-grooved pulley turned by toothed gearing and driving pulley, then over a guide pulley and another groove of the double-grooved pulley, from which pulley the upper and lower parts of the rope pass to the carriage, and then over a pulley at the end of the tramway. There are other details included in the specification.—Patent abandoned.

2447 J. E. BOYCE and R. HARRINGTON. *Improvements in umbrellas and parasols.* Dated August 28, 1867.

The patentees claim applying to the stick of the umbrella or parasol two bow-shaped springs provided at their middle with a raised part or nib, with the raised part or nib of one or other of which springs a slot in the runner is made to engage to fix the umbrella or parasol in its open or closed position, substantially as described and illustrated in the drawings. Second, steadying the runners of umbrellas and parasols having taper sticks by bow springs made from sheet steel, or other elastic metal, substantially as described and illustrated in the drawings.—Patent completed.

2448 W. WILSON and J. COWBURN. *Certain improvements in looms for weaving.* Dated August 28, 1867.

This invention relates to that description of looms which have movable shuttle boxes actuated by the mechanism known as "Diggle's chain," and are employed for weaving patterns, and the invention is designed for effecting a continuous action of the said chain, so that one pattern may be woven continuously when desired without the regular motion of the "star" wheel affecting it so as to alter the pattern. Second, the invention is designed to enable the shuttle to make several "picks" to each "card." —Patent abandoned.

2449 G. G. TANDY. *Improvements in the preparation of vulcanizable compounds, and in the manufacture of articles therefrom.* Dated August 28, 1867.

This invention consists, under one head, in an improvement in the mode of preparing compounds of india-rubber and sulphur, or other vulcanizable gums or resins used for making ebonite or vulcanite, so as to render them more plastic than can at present be attained, whereby a great amount of labour and expense is saved. Hitherto little or no solvent has been used in these compounds in consequence of the great amount of porosity resulting from the escape of the vapours generated during the process of vulcanization (or hardening). This escape of the vapours the inventor overcomes by exposing the moulded articles to a sufficiently high temperature to expel the solvent previous to subjecting them to the indurating process; and he finds that, by using petroleum spirit not having a higher specific gravity than ·630 (although a higher specific gravity may be used) the expulsion is easily effected, and that the resulting vulcanite or ebonite will be of a much more elastic and tougher nature than that produced without the aid of such solvent.—Patent abandoned.

2450 W. PEDDER. *Improvements in brushes.* Dated August 28, 1867.

This invention consists in the manufacture of skeleton brushes, namely, brushes open at the back, in order to prevent the accumulation of dirt or wet at the bottom of the bristles or hairs.—Patent completed.

2451 J. ELLIOTT. *Improvements in machinery used in cutting coal, stone, slate, and other minerals, and in forming tunnels and galleries, and for other quarrying purposes.* Dated August 28, 1867.

This invention consists in machinery for driving a circular rotating disc or discs, either with teeth, or formed to receive movable tools of varied form set in a slightly spiral line in the direction of the forward cut, and in facilitating the removal of the core produced by the forward cut by a cranked arm or arms connected by a pivot joint to the disc or discs, entering the forward cut with the disc or discs, and set in action in order to cut the core at back by the portion of the cranked arm without the cut operating on that within it; or by a key and spindle connected with an arm used as a back core cutter setting such arm in action.—Patent abandoned.

2452 J. H. JOHNSON. *Improvements in apparatus for the aeration of fresh water obtained by the distillation of sea water.* (A communication.) Dated August 28, 1867.

The apparatus for carrying out this invention cannot be described without reference to the drawings.—Patent completed.

2453 J. STOREY, W. E. BICKERDIKE, and W. V. WILSON. *A new method of bronzing metallic and other surfaces.* Dated August 28, 1867.

It is well known that all the dye stuffs produced from aniline, such as roseine or magenta, aniline or phenyl, blues and violets, all the violets and green dyes produced by the action of the iodides of the alcohol and beta alcohol radicals upon rosaniline, possess a brilliant bronze-like lustre in the solid state. This new method of bronzing metallic and other surfaces consists in the application of solutions, more or less concentrated, of the above-named dyes in alcohol, or other volatile solvent, to polished surfaces (or to surfaces prepared by Japan varnish or paints), such as iron, steel, and other metals, papier mache, and paper rendered impervious by varnish, or other well-known means, porcelain, slate, enamel, leather, bone, ivory, wood, or straw, when, by the evaporation of the solvent at ordinary or elevated temperatures, a film of the solid dye stuff remains upon the surface, presenting its characteristic lustre.—Patent completed.

2454 W. T. WATTS and D. J. FLEETWOOD. *Improvements in, and applicable to, hydraulic and other presses, parts of which improvements may be employed for, or with, other descriptions of machinery.* Dated August 28, 1867.

This invention relates to a former patent granted to D. J. Fleetwood, dated April 9, 1867, in the specification of which former patent was described a press consisting of a hydraulic cushion as a bed or anvil, and a forcer worked by steam or other power, which press was applicable to the manufacture of hollow forms, the cutting out or piercing of blanks, and to other similar uses. The patentees propose by the present improvements to render this compound press applicable to the purposes of coining, medalling, punching, shearing, and other analogous operations, as well as the manufacture of hollow or tubular forms. The press consists of a hydraulic ram arranged to act as a cushion or anvil, upon which a die or dies or tools may be suitably secured, and the blow or pressure is given by a top forcer working in a guide, and actuated by cam, eccentric, or other suitable medium; and with this description of press, when used in the manufacture of hollow or tubular forms, they propose to employ a pressure plate capable of being acted upon or held down upon the surface of the metal blank under operation by hydraulic rams governed by valves or weights, leverage or springs bearing upon the pressure plate with sufficient power to retain it in position, so that the metal will be drawn equally, and without buckling, from beneath the plate as the forcer operates; and which pressure accommodating itself to the gradual thickening of the periphery of the blank, permits the inner or middle surface to be forced into or through the mould, die, or shaping tool by the forcer or ram. This resilient or self-acting pressure plate may also be used with other kinds of presses, stamps, or hammers.—Patent completed.

2455 W. B. SMITH. *An improved construction of lever watch movements.* Dated August 28, 1867.

This invention is not described apart from the drawings. —Patent completed.

Digitized by Google

2456 R. EDWARDS. *Improvements in the construction of locomotive traction engines.* Dated August 28, 1867.

This invention relates, firstly, to means of avoiding the difficulty hitherto experienced in the boilers of locomotive and traction engines when travelling up and down inclines. In constructing such boilers the inventor proposes to divide them transversely into two or more compartments, and to connect the steam spaces of each division by pipes or otherwise. The water spaces he also connects together, but he places valves in the connections, so as to be able to open or close communication between the divisions. The invention relates, secondly, to the construction of gear used in conveying motion (in locomotive engines especially) from the crank or other shaft to the driving shaft wheels or other shafts. The last improvement consists in mounting the axle of the driving wheels (in locomotive engines that are driven by a pitch chain geared to the driving axle) in slots or in links, and by screws or keys shifting the axle in a line with the centres of the pitch chain wheels for taking up any slack chain.—Patent abandoned.

2457 J. MACINTOSH and W. BOGGETT. *Improvements in springs for boots and shoes.* Dated August 29, 1867.

According to one method of carrying out this invention the patentees take two pieces of sheet india-rubber (previous to its being vulcanized or converted, so as to render the same permanently elastic, as is well understood), of the size and shape of the boot or shoe spring required, and coats them on one side with india-rubber cement. They then place the two cemented sides together with a strip of tape or woven fabric inserted between them at the edges to prevent the stitching from giving way when applied as a spring to the upper of a boot or shoe.—Patent completed.

2458 C. D. ABEL. *A new or improved process for the direct production of phosphorus for industrial purposes.* (A communication.) Dated August 29, 1867.

Here phosphate of lime in the form of either apatite, bones, fossil, phosphates, or in any other form, is introduced in a pulverized state in a closed vessel, where it is mixed with twice its weight of silica, also in a pulverized state, in the form of sand, sandstone, or in any other suitable form; charcoal, coal, or coke dust is then added to the extent of twenty-five per cent of the weight of the phosphate, and the mixture is then heated to a temperature between an orange red and a white heat. The silica then re-acts upon the phosphate to form silicates of lime, and the liberated phosphate acid is completely decomposed by the carbon, thus producing phosphorus, which is volatilized and collected in a receiver in any known manner.—Patent abandoned.

2459 H. J. SIMLICK. *Improvements in cigar and pipe lights, and in their mode of construction, composition, and manufacture.* Dated August 29, 1867.

Here the inventor takes ordinary wooden splints, and envelopes them with a coating or network of metallic wire, or sheet or other metal, in conjunction with cotton, by an ordinary braiding machine, and dips them in a pastile composition. By preference he uses four parts of gum, ten of chlorate of potass, three of fine powdered charcoal, one of gum benzoin, and eight of Gascarilla bark. The wire to which the pastile composition has adhered has a permanent hold upon, and to, its stem, and is not liable to fall off.—Patent abandoned.

2460 A. STEWART. *Improvements in textile fabrics, and in the apparatus or means employed for effecting the same.* Dated August 29, 1867.

This invention relates to arrangements of mechanism for printing warps by which new effects are produced upon the cloth made with warps so treated, and consists as follows:—The part of the warp to be printed is carried upon a beam in the ordinary manner, and is led therefrom over a roller on which the blanket used in warp printing machines travels, from which point it is conducted round a steam can, and thence to the warp beam. Near to that point where the warp passes over the blanket, one or more revolving printing rollers are placed which revolve in proximity to the warp as it travels, and, therefore, being supplied with printing liquid, the pattern of the roller or rollers is transmitted to the warp. To produce the new appearance upon the cloth, it is necessary to separate the printed warp threads by warp threads of another colour. This is effected by putting the other half of the warp upon a separate beam, and in passing the printed and unprinted warp threads through separate splits in a reed, after passing through which the two parts of the warp are wound up upon the warp beam ready for being placed in the loom to be woven into cloth. —Patent completed.

2461 J. DOUGLAS. *Improvements in the means of ventilating and regulating the draft of close fire ranges or kitcheners.* Dated August 29, 1867.

Here the patentee makes an aperture at any suitable point in the front or side of the range above the fire, and communicating with the flue. This opening he provides with a door or flap, hinged or otherwise mounted, of a size to fill up the whole area of the flue; this flap is held in any suitable position by a bent arm attached thereto, having teeth or notches catching in a guide fixed at the upper part of the aperture; or it may be otherwise arranged to hold the flap more or less open, as desired. By adjusting the position of the flap, which acts both as a ventilator and damper, the draft in the flue may be regulated according to the requirements.—Patent completed.

2462 C. SLAGG. *Improvements in the application of sewage and other liquid manures to land.* Dated August 29, 1867.

This invention consists in laying down in the land a system of tubes or channels by which the liquid manure is distributed in sufficient proximity to the roots of the plants or crops to which it is applied, instead of on the surface, as heretofore. These channels may be in the form of drain tiles, and laid in like manner to such tiles; these tubes or channels are placed in connection with culverts or main channels or pipes carried along the headlands of the fields or otherwise.—Patent abandoned.

2463 J. and G. W. DYSON, and S. MARTIN. *An improved mode of cutting up iron and steel rails, and rail ends, in order to utilize them.* Dated August 22, 1867.

The patentees claim cutting up iron and steel rails and rail ends longitudinally at each end of the web by circular cutters, substantially in manner and for the purpose described.—Patent completed.

2464 J. and R. D. PAULIN. *Improvements in apparatus for feeding paints on the stone or stones on which they are to be ground.* Dated August 29, 1867.

The patentees make a receiver for the paint of any convenient size, form, and material, within which, and at the bottom thereof, is a knife (by preference double curved) revolving on its spindle; at the side of the receiver is an opening with arrangements for closing the same to a greater or less extent, as may be desired. The knife during its revolutions pushes some of the paint through the opening in the side of the receiver into a box. Another knife moved by a crank at the proper time cuts off that portion of the paint which projects from the receiver into the box, and in travelling back to its former position carries such portion of paint to a position immediately over or communicating with the eye of the stone; and provision is made for raising the knife preparatory to its being moved again towards the receiver, so that the paint is dropped which falls or is conveyed into the eye of the stone.—Patent completed.

2465 W. MUIR. *Improvements in apparatus for starting, propelling, and stopping, railway trains or carriages, and ships or vessels.* Dated August 29, 1867.

This invention consists in starting, propelling, and stopping railway trains or carriages by the adoption of a system of endless chains, bands, wire, or other ropes, one at least of such endless chains, bands, or ropes being used for a given length of the railway, and being conducted along each side thereof (near to each rail, for instance), and over wheels or pulleys situated at right angles to the lines of rails, or at the ends of the lines of rails, or in any other suitable position. One or both the wheels may be used as driving wheels, besides which the patentee uses other wheels or pulleys as guides, one at least being adjustable for tightening the chain rope or band.—Patent completed.

2466 A. M. CLARK. *Improvements in apparatus for submarine exploration.* (A communication.) Dated August 29, 1867.

This invention consists in combining with the working chamber or chambers in which the explorers are to be placed a reservoir or reservoirs containing air, forced in before sinking, compressed to such an extent and in such quantity, and so combined with the said working chamber or chambers, that the explorers inside may draw the required supply from the reservoir to suit their own demands for respiration, and to control the buoyant or rising power of the apparatus, or sustain it with the top above water when the top is open for any purpose.—Patent abandoned.

2467 W. E. NEWTON. *Improved steering apparatus.* (A communication.) Dated August 29, 1867.

Here, on the upper part of the rudder post, a collar is firmly secured, and is provided with three radial recesses to receive a dog, which is pivoted in a plate or stock firmly secured to the deck. When the dog is raised, the rudder is free to turn, but when the dog is let down and adjusted in any one of the recesses of the collar, the rudder will be held firmly in position, and may be retained in any of the positions necessary in sailing a vessel, or when the same is lying in port. To the upper end of the rudder head there is firmly attached a toothed segment, the teeth being pendent or projecting downward, and into the teeth of this segment gears a pinion on a shaft which carries a spur wheel which gears into a pinion on the hand wheel shaft.—Patent abandoned.

2468 A. M'N. and M. A. WIER. *Improvements in signalling and indicating apparatus.* Dated August 29, 1867.

Reference to the drawings is essential for a full description of this invention.—Patent completed.

2469 W. E. NEWTON. *Improvements in rudders.* (A communication.) Dated August 29, 1867.

This invention consists in constructing the rudder with a wrought or hollow cast-iron post provided with a projecting V-shaped feather for receiving the back of the blade of the rudder, which is of wood, and is secured to the post by metal straps which pass round the post, and are fixed to the blade by transverse bolts. The rudder post is secured to the stern post of the vessel by means of similar straps which pass round the rudder post and lie in recesses made in the rudder post. These recesses admit of the post having considerable endway or vertical motion. The post is supported from above by a collar which rests on a plate let into the deck.—Patent abandoned.

2470 J. SILVESTER. *Improvements in spring balances.* Dated August 30, 1867.

Here the patentee makes the trough-like frame or case of the balance open at its front and at its bottom end. The top of the helical spring of the balance is hooked to a pin or projection at the top of the case, and the bottom of the spring carries a movable bottom plate, which, when the spring is in its contracted or normal position, closes the open bottom described of the case of the balance. To the bottom or closing plate described a flat plate, nearly as long as the balance, is fixed. To the top of this flat plate the finger or pointer of the balance is fixed. The helical spring bottom and flat plates being fixed together, they are placed in the case of the balance, and the top of the spring is hung to the top of the said case. The parts described are fixed in their places, and the front of the case is covered by a dial plate having a slot in its middle, in which slot the finger or pointer on the flat plate works. The top of the case carries a ring or loop by which the balance is suspended, and the movable bottom plate carries a hook to which the article to be weighed is hung. On placing a weight on the hook described, the helical spring is elongated, and the lower part of the spring, and the bottom or closing plate and flat plate connected with the said spring, are made to project from the bottom of the case of the balance. By the elongation of the spring and the descent of the flat plate, the pointer carried by the said flat plate traverses the slot in the dial plate and indicates upon the dial plate the weight hung on the balance.—Patent completed.

2471 A. M. CLARK. *Improvements in the mode of removing and cutting the hides of animals for the manufacture of driving bands or tubes of leather.* (A communication.) Dated August 30, 1867.

This invention relates to the production of driving bands and tubes of great length of leather without joins or rivets, or with only one join. In order to obtain them the patentee adopts a new mode of skinning the animal from which the hide is obtained, and also of cutting up the hide. One method is as follows:—The hide is cut along the line of the back, and then in the line of the longitudinal axis of the head, and also along the whole length of the belly. The hide in this manner will be severed in two parts, except in the hind part, which serves to connect them, and when the hide is opened out, strips double the length of the animal may be cut therefrom.—Patent completed.

2472 R. WEARE. *Improvements in furnaces.* Dated August 30, 1867.

In arranging steam boiler and other furnaces the inventor forms the firedoor as an open frame, into which, on the side next the fire, a number of plates of zig-zag form are fitted, so as to leave air passages of a similar form between them. On the outside of the door there are lower plates by which the admission of air to the passages may be regulated. The firebars are cast with curved notches in their sides at short distances apart, so that when the bars are set up for use they form a grate or surface with numerous passages through it for the passage of air to the fuel. A water cistern with a supply and an overflow pipe is provided in the ash-pit beneath the firebars.—Patent abandoned.

2473 I. DIXON. *An improved submerged propeller for navigable vessels.* Dated August 30, 1867.

To construct a propeller according to this invention, the boss or nave may be oval-shaped, or egg-ended, from which spring two or more flat, or nearly flat, blades set at the required angle to the driving shaft on which the propeller is mounted. When these blades are made from plates of sheet metal, it is preferred they should be tapered or chamfered off at one or both sides of the outer edges, so as to form feather or sharp edges on outer rims of the blades, and when the propeller or blades thereof are constructed of cast metal to ensure strength and easy evolution in the water, it is preferred to form the back and front surface of the blades slightly convex, that they may have sharp edges, and the body of the metal of which they are formed placed in the best position to ensure maximum mechanical strength in the amount of the material employed, and at the same time prevent the least possible resistance to their evolution in the water.—Patent completed.

2474 M. HAMMERSTEIN. *Improvements applicable to cigars, cheroots, cigarettes, pipes, and other smoking tubes.* (A communication.) Dated August 30, 1867.

To apply this invention to (say) a cigarette, a thin film of cork of (say) from half an inch to three-quarters of an inch wide, on one side of which is applied any suitable waterproof composition of gum, glue, &c., which is then rolled round the end of the cigarette that is to be placed between the lips, thus forming a cylindrical belt encompassing the inner end of the cigarette.—Patent completed.

2475 A. H. BRANDON. *An improved carpet stretcher and tack driver.* (A communication.) Dated August 31, 1867.

This invention consists in arranging and combining together two parts, one the shaft for the stretcher, the other the tube and operating parts for the tack driver, these operating parts being, first, a plunger or hammer. Second, a spring by which the hammer is operated. Third, a peculiar shape to the lower part of the plunger by which the descent of the tack is regulated. Fourth, the jaws which hold the tack ready to be driven into the floor by the blow of the plunger, and which open at the required moment to allow the tack to pass.—Patent completed.

2476 J. A. BROWN. *Improved apparatus for propelling ships and other vessels, and for actuating machinery applicable to other purposes.* Dated August 31, 1867.

This invention, when applied to the propulsion of ships and other vessels, consists in the construction and arrangement of two or more separate horizontal propellers attached to either side of the keelson, either at the stern or bows, or amidships, or at all such parts within or outside the lines of the ship or vessel to be propelled. The patentee claims the mechanism described, and shown in the drawings, as a combined apparatus for propelling ships or other vessels; but more especially he claims the peculiar mechanical contrivance of feathering the fin blade or propelling arm, and the manner of performing and regulating the same in the various positions of its stroke; and also employing the same mechanism as a motive power for actuating machinery by the pressure of wind or water. —Patent completed.

2477 W. J. MATTHEWS. *Improvements in breech-loading firearms.* Dated August 31, 1867.

The patentee claims constructing and arranging breech-loading firearms as described. He also claims closing the breech of the barrel by a block turning in behind it about a transverse axis, and being then secured by a second block carried by the first block on a longitudinal axis, and moving in rear of the first block, as described. He also claims constructing and arranging the extractors, as described.—Patent completed.

2478 W. AUBERT. *Improvements in apparatus for diffusing odours or perfumes.* Dated August 31, 1867.

According to this invention the inventor employs for evaporating perfumes an apparatus of an ornamental form, consisting of a covered reservoir in which the perfume is placed, and through the cover of this reservoir a large number of holes or perforations are formed, through which small strips of sponge, &c., are inserted. These strips suck up the perfume from the reservoir in its liquid form, and expose it to be evaporated on their ends, which are above the cover, and present an extended evaporating surface. In this way the composition of the liquid in process of evaporation is maintained until it has all volatilized, identically what it was at the commencement of the operation. The cover supports an ornamental vase which forms a funnel for supplying the reservoir from time to time.—Patent abandoned.

2479 A. FENTON and J. SANDILANDS. *Improvements in machinery to be employed in the manufacture of fish hooks and fishing rods.* Dated August 31, 1867.

This machinery consists of a horizontal shaft working in bearings, and provided with a flywheel and fast and loose pulleys. Upon the shaft two steel cylinders are mounted, one of the said cylinders being provided with semicircular grooves, and the other with V-shaped grooves. The said grooves of the cylinders are made into filing or cutting surfaces, and are of different sizes for filing different sizes of fish hooks. The cylinders or circular files are composed of a series of steel discs strung upon the shaft, and bound together by collars. The fish hooks to be filed or finished are fixed in a holder upon a horizontal table or slide working in a dovetail on the bed of the machine. A rapid rotatory motion being given to the cylinders or circular files, the table carrying the fish hooks is advanced by a lever towards the said circular files, and the points of the barbs of one set are filed or finished by the semicircular grooves of one circular file, and the sides of the barbs of another set are filed or finished by the V-shaped grooves of the other circular file. The fish hooks are fed to the holder by hand, or by a hopper, or otherwise.—Patent abandoned.

Digitized by Google

2480 D. NICOLL. *Improvements in electric telegraph conductors, and in the means of laying and securing the same, also in the machinery and apparatus to be employed therein.* Dated August 31, 1867.

The patentee claims the use and application of a locomotive steam engine or machine for opening and preparing earth, soil, or sand to receive underground telegraphic wires, and for supplying the trenches so prepared with insulating material or waterproof compound for an extra or final insulation and protection of the wire or wires when such have been received or laid therein in lengths or rigid sections, such wire or wires having been previously and separately insulated, and when several are used solidified together, as described in the specifications of two former patents, and more particularly in that dated March 11, 1867 (No. 694). He also claims the completion of the junctions of a continuous wire or wires by the use of percussion or compression obtained by steam, hand, or other machine, all substantially as specified.—Patent completed.

2481 E. K. DUTTON. *Improvements in window sash fasteners, which are also employed to sustain the window sashes in any desired position when the window is opened.* (A communication.) Dated September 2, 1867.

Here a lever works in a "frame" or "fixing" of a suitable form and material, the fulcrum of the lever being nearer to one end than the other, the shorter end of the lever having been suitably formed to have affixed thereto a pad of caoutchouc, &c., and the longer end of the lever being suitably shaped to be operated upon by the hand. The frame and lever are affixed to the side of the "sash frame," or so let into the same that the pad of caoutchouc is pressed against the fixed window frame in which the sash slides, a spring operating upon the lever to give the said pressure; when the window is closed, a projecting portion of the lever enters a slot in a metal plate affixed to the window frame and effects the desired fastening.—Patent abandoned.

2482 H. O. W. and E. F. COOPER. *An improved method of watering roads, streets, and other places.* Dated September 2, 1867.

The patentees claim the use of chloride of calcium, or chloride of magnesium, and common salt or rock salt in water for watering roads.—Patent completed.

2483 R. WATSON. *Improvements in brakes for railway trains, parts of which can be used or applied for signalling on trains in motion.* Dated September 2, 1867.

This invention relates, first, to an arrangement of mechanism to be applied to railway carriages when coupling chains or ropes are employed to connect the brakes from one carriage to another, and has for its object to keep the chains or ropes tight at all times. In carrying one part of the invention into effect the inventor connects or couples to the carriages, or between the brakes on the carriages next to each other, an arrangement of three, four, or more levers; he prefers four. These levers are jointed together at their ends on studs, the number of the studs being the same as the number of the levers, on which they are free to move. On the studs, pulleys or rollers are fitted, and the coupling chains or ropes are passed over these. The levers, studs, and pulleys or rollers when fitted together and placed in position (four levers being used) are of a diamond form in outline, and whether drawn out longitudinally by the carriages moving further apart, or folded up by the carriages coming nearer together, the same quantity of chain or rope is required to pass over them.—Patent abandoned.

2484 C. GELSTHARP. *Improvements in the manufacture of malleable iron, cast iron, and steel, and in the construction of furnaces to be employed for such purposes.* Dated September 2, 1867.

The patentee claims, first, the construction of the blast gas furnace which separate melting and reducing chambers, and the arrangement of a separate fuel chamber, as described and set forth. Second, the construction of furnaces for reducing iron ore with solid or gaseous fuel by direct heating with a non-oxidizing flame passing under the ore bed, before or after passing over the ore, as described and set forth. Third, the application of the gas blast furnace to the melting of spongy iron, as described and set forth. Fourth, the methods of treatment in the manufacture of malleable iron, cast iron, and steel, substantially as described and set forth.—Patent completed.

2485 A. V. NEWTON. *An improved manufacture of tool for cutting stone.* (A communication.) Dated September 2, 1867.

This invention relates to a novel saw or rotary cutting tool. The edge or periphery or perimeter of the cutting tool is studded with small precious stones of great hardness or pieces thereof (diamonds being preferred), the same being so disposed that the stones shall form the cutting edges or points of the saw, some of them projecting on either side of the saw plate to cut a "kerf" sufficiently wide to keep the plate from binding in the kerf.—Patent completed.

2486 H. VALLANCE. *Improvements in fastenings suitable for casement windows.* Dated September 2, 1867.

The patentee claims combining with the latch fastening of a casement window a rod passing along the frame to a pin or bolt locking with a quadrant, in such manner that the movement of the latch handle is communicated to the said locking pin or bolt, as described.—Patent completed.

2487 C. TESSIER. *Improvements in the apparatus for moderating or regulating the feeding of the pulp in paper machines.* (A communication.) Dated September 3, 1867.

This invention is not described apart from the drawings.—Patent completed.

2488 W. R. PAPE. *Improvements in breech-loading firearms.* Dated September 3, 1867.

This invention relates to breech-loading firearms, more especially to that class of arm commonly called "drop down" guns, and consists, first, of an improved action and cartridge extractor, by which action the empty cartridge case, after the piece has been fired, is drawn out by the act of opening the breech, instead of being pushed out in the ordinary way. The invention further consists of an improved form of locking down wedge by which the wear is compensated. Another improvement consists in fitting an anvil or striker to the cock; this anvil is actuated by the motion of the cock as it is drawn back by hand, or driven forward by the lock mainspring.—Patent completed.

2489 A. FIELD and W. B. NATION. *Improvements in ornamenting candles, and in apparatus or machinery employed for that purpose.* Dated September 3, 1867.

One part of this invention consists in producing upon the surface of candles helical or straight grooves, and in filling such grooves with wax, stearine, paraffin, or other suitable fatty matter of a different colour or colours from that of the candle. Another part has for its object to produce candles with ornamental designs upon their surfaces by folding moulds.—Patent completed.

2490 A. LEIGH. *An improved compound or composition to be employed in sizing and finishing woven fabrics and yarns.* Dated September 3, 1867.

This invention consists in mixing together the following ingredients in about the proportions given, and in applying the composition to woven fabrics or yarns as a sizing material. The inventor takes about six pounds of yellow resin, and about four pounds of pearl ash, and dissolves them in about twenty-five gallons of hot water; he then adds thereto about four pounds of farina, and six pounds of brown whitening, and thoroughly intermixes the whole, which is then ready for use.—Patent abandoned.

2491 J. M'KECHNIE. *Improvements in apparatus for applying concentrated heat, and suitable for lighting fires, brazing, and similar uses.* Dated September 3, 1867.

This invention consists in adding to ordinary portable bellows an equalizing air compartment compressed by a spring weight, and by fitting thereto a duplex nozzle in place of the ordinary one, such duplex nozzle having a central channel for the air, and a concentric annular channel for gas, or for oil or other burning fluid. When made for gas, the nozzle has fitted to it a small stopcock to receive a small flexible tube from any convenient gas-pipe or bracket; but when made for oil, it has fitted to it a small receptacle for the oil; and if the apparatus is made for lighting house fires, the receptacle may be made of a size to contain the small quantity requisite for lighting one fire. A wick is, by preference, used with the oil, and the annular channel must be made large enough to receive it, and in two parts that can be separated so as to introduce it.—Patent abandoned.

2492 A. E. GELHAYE. *Improvements in machines for manufacturing chains, cords, ropes, and the manner of making such chains, cords, and ropes.* Dated September 3, 1867.

The patentee claims the construction of a machine, as described, or a modification thereof, with an eccentric grooved cylinder, hollow centre pinion, or grooved pillar, with rising and falling slides, needles, and clutches, the whole being worked by steam or hand power, or by treadle, if preferred.—Patent completed.

2493 P. F. LUNDE. *Improved apparatus for obtaining extracts from vegetable substances.* Dated September 3, 1867.

The patentee claims causing the water to pass through successive layers of the vegetable substance intended to be operated upon, in such order that the water is always made to pass first through the first layer or charge of vegetable substance, and in succession through those layers or charges which have been subsequently added, as set forth.—Patent completed.

2494 E. Y. ROBBINS. *Improvements in firegrates.* Dated September 3, 1867.

This invention consists in forming the front of the grate basket, or part of the grate in which the fuel is held, concave in its horizontal or vertical, or in both its horizontal and vertical sections, so throwing the fuel into such position that there is cross radiation from one part of the front of the fuel upon another part, keeping the entire front surface of the fuel hot and brightly incandescent; also forming a highly heated channel of draught, drawing up smoke and the dust of ashes into the flue, this channel of draught being entirely within the fireplace or stove, and the bars so shaped that any smoke coming from the fuel between the bars is under the arch and within the jambs, and not likely to get out into the room.—Patent completed.

2495 L. N. LE GRAS. *Improvements in milk cans.* Dated September 3, 1867.

This invention consists, first, in making milk cans of two or more thicknesses of tin, &c., the space or spaces between the thicknesses being filled with charcoal, or other non-conductor of heat, so that milk placed in the can is not affected by change of temperature. Second, in compressing the milk when in the can so as to make it, as it were, a solid body incapable of any movement.—Patent abandoned.

2496 E. T. ARCHER. *Improvements in spring mattresses.* Dated September 3, 1867.

The patentee claims constructing mattresses of a combination of wood laths and springs, and accessory parts, arranged and applied in the manner and for the purpose described.—Patent completed.

2497 A. M. CLARK. *Improved machinery for cutting, carving, and engraving upon ivory, wood, stone, metals, and other substances.* (A communication.) Dated September 3, 1867.

This invention is not described apart from the drawings.—Patent completed.

2498 G. SMITH. *Improvements in ladders suitable for fire-escapes and other purposes.* Dated September 4, 1867.

According to this invention the inventor combines two or more ladders, according to the amount of extensibility required, disposed one within the other, the inner ones being capable of sliding in the outer ones. The outer ladder of the series is pivoted or carried on hinges or centres at its lower end, such centres being fixed on a carriage mounted on wheels for the facility of transport. There are various other features comprised in the invention.—Patent abandoned.

2499 G. CRANE. *Improvements for speedily and effectually removing snow from roads and streets.* Dated September 4, 1867.

Here the patentee proposes to provide a small steam boiler on a land carriage drawn by one or two horses for the production of steam at a pressure of about 40lb. The boiler is to be provided with pipes or hose to convey the steam and apply it as follows:—A gang of men is to be employed in bringing the snow by scraping it up, or in hand barrows, from the more distant parts, that is, from equal distances between the openings to the sewer to the openings. A perforated iron shield is to be placed over the opening, to keep the snow from actual contact with the grating of the sewer. The pipe or hose from the boiler is to be inserted beneath this shield, and the steam allowed to play upon the snow as fast as the latter can be conveyed and piled upon the shield.—Patent abandoned.

PROVISIONAL PROTECTIONS.

Dated January 22, 1868.

224 C. R. Broadbent, Southampton-buildings, Chancery-lane, doctor of medicine. Improvements in the manufacture of shoes.

Dated January 25, 1868.

272 F. Wirth, Frankfort-on-Maine, Germany. An improved apparatus for heating, evaporating, and decomposing water, oil, and other substances. (A communication.)

Dated January 27, 1868.

282 W. Ellis, Colwick-lane, Sneinton, Nottinghamshire, scaleboard cutter and box maker. Improvements in, or applicable to, circular or rotating machines for cutting wood by hand or steam power, for making laths, cards, strips, or slices of wood and other articles.

Dated February 3, 1868.

369 J. Offord, Oxford-street, and S. W. Hale, Paddington, coach builders. Improvements in public and private carriages and vehicles, in regard to opening and closing the heads or hoods of those having movable heads or hoods, and opening and closing the doors of public and private carriages and vehicles generally.

Dated February 10, 1868.

450 A. M. Clark, Chancery-lane. Improvements in breech-loading ordnance and projectiles. (A communication.)

Dated February 13, 1868.

489 C. Blyth, mill manager, Dundee. Improvements in machinery and apparatus for measuring and cutting cloth for bags and for other purposes.

Dated February 15, 1868.

515 L. Mummenhoff, Saint Mary Axe, City. Improvements in compositions for the manufacture of building blocks, and for use in building. (A communication.)

Dated February 18, 1868.

526 A. M. Duflihol, Passage des Petites Ecuries, Paris, Captain and Adiutant Major in the 5th Regiment of Dragoons of the French Army. An improved method of shoeing horses, and other beasts of burden.

Dated February 20, 1868.

571 W. E. Newton, Chancery-lane. Improvements in mechanical movements adapted for use in clocks and watches, and wherever else it is desired to multiply motion or to convert speed into power. (A communication.)

Dated February 22, 1868.

589 R. B. Mitchell, Sheffield, edge tool maker. An improved method for making plane irons, sheep shears, and other edge tools.

Dated February 24, 1868.

604 H. Chamberlain and J. Craven, Wakefield, Yorkshire, engineers, and H. Wedekind, Dunster-court, Mincing-lane, City, engineer. Improvements in the burning of bricks, lime, cement, and other like substances, and in the kilns employed therein. (Partly a communication.)

Dated February 25, 1868.

618 J. Vevers, Leeds, machinist. Improvements in spinning and twisting machinery. (A communication.)

628 F. Remy, Rue du Faubourg St. Martin, Paris, manufacturer. An improved steel seat or chair.

Dated February 26, 1868.

640 T. Lythgoe and H. Thornton, Manchester, joiners and builders. Improvements in the construction of walls, floors, and roofs for buildings in which concrete and iron are used, and in apparatus employed therein.

Dated February 27, 1868.

654 F. Dumas, Passage des Petites Ecuries, Paris, proprietor. Improvements in bathing dresses, for the treatment of skin and other diseases.

665 W. E. Newton, Chancery-lane. Improvements in pens and pen and pencil holders. (A communication.)

670 G. Hart, Wakefield, Yorkshire, engineer. An improved mode or method of, and apparatus for, effecting the consumption or prevention of smoke in steam boiler and other like furnaces.

Dated February 28, 1868.

673 J. Livesey, Victoria Chambers, Westminster, engineer. Improvements in coupling, driving, and retarding locomotive carriage or other wheels on railways, or for other purposes.

680 J. Dunkerley, Denton, Lancashire, hat manufacturer. Certain improvements in the method of manufacturing hats or coverings for the head, and in apparatus employed therefor.

Dated February 29, 1868.

690 E. Baker, Charles-street, Mortimer-street, Middlesex. Improvements in the formation and application of screw bolts.

691 H. B. Wilder, Sulham House, Sulham, Reading, Berkshire. Improvements in magnetic electric telegraphic apparatus for signs, letters, or sentences, with bell and self-acting mechanical switch.

692 J. Collins, Dawson-street, Dublin. Improved apparatus for filling cartridge cases for breech-loading guns.

693 L. C. Detouche, Rue St. Martin, Paris, clockmaker. Improvements in apparatus for registering the number of passengers travelling by public conveyances, and the amount of fares paid.

696 W. Smith, J. Giddings, and J. Rank, Hull, Yorkshire. A new or improved fire-escape.

698 R. Zwez, Harrington-street, Hampstead-road. A new or improved can for containing petroleum, paraffin, hydrocarbons, and such like oils or spirits, and other liquids.

700 W. Barford, Peterborough, Northamptonshire, and T. Perkins, Hitchin, Hertfordshire. Improvements in apparatus for raising and stacking straw and other agricultural produce.

702 L. B. Schmolle, Aldermanbury, City, manufacturer. Improvements in skeleton skirts.

Dated March 2, 1868.

706 W. Rollo, Dundee, Forfarshire. Improvements in the arrangement and construction of water-closets.

708 W. E. Newton, Chancery-lane. Improved apparatus for burning hydrocarbons for heating purposes. (A communication.)

710 T. Horsley, Coney-street, York. Improvements in breech-loading firearms.

712 A. Smith, Litchurch, Derbyshire. Improvements in the construction of railway waggon axle boxes.

Dated March 3, 1867.

714 W. E. Gedge, Wellington-street, Strand. A mineral paper-hanging intended to preserve apartments from dampness. (A communication.)

717 F. Moss, Eccles, Lancashire. Improvements in apparatus for registering passengers travelling by public vehicles, and in the construction of certain vehicles to be used in combination therewith.

Digitized by Google

719 T. Bisset, Marlee, Blairgowrie, Perthshire, implement maker. Improvements in reaping and mowing machines.

720 W. B. Thompson and W. Gall, Dundee, Forfarshire. Improvements in machinery or apparatus for winding yarns or threads.

721 J. A. Haswell, Gateshead, Durham, engineer, and G. Brown, York, carriage builder. Improvements in signal apparatus to be used in railway passenger trains.

722 J. Manly, Birmingham, brassfounder. Improvements in nails which are used upon furniture, saddlery, and trunks, and for other useful and ornamental purposes.

723 W. Spence, Quality-court, Chancery-lane. Improvements in machines for making nails. (A communication.)

724 H. Zox, Nelson-square, Blackfriars, hat manufacturer. Improvements in the manufacture of hats and caps, and other coverings for the head.

725 W. Whittle, Harborne, Staffordshire, mechanical engineer. Improvements in steam engines and steam boilers.

726 J. Dewar, Kirkcaldy, Fifeshire, doctor of medicine. Improvements in preserving blood for use as food.

727 G. Anderson, Northumberland-street, Strand, gas engineer. Improvements in apparatus for moulding and compressing substances for artificial fuel.

728 E. Burton, Clapton, Middlesex, and J. Lawrence, Uckfield, Sussex, engineers. Improvements in machinery for screening and sifting coals, cinders, and other matters.

729 H. Kennedy, Southampton-buildings, Chancery-lane. An improved machine for cutting files.

730 S. A. Bell, Bow-lane, City, and G. H. Higgins, Fairfield-road, Bow, machinist. Improvements in the manufacture of match boxes, and in apparatus to be used therein.

731 T. Johnson, Runcorn, Chester. Improvements in treating ores to obtain copper therefrom, and in evaporating brine.

732 J. W. and C. R. Harrison, Hampstead-road. Improvements in parallel rulers.

733 B. W. A. Sleigh, Langham-place, Portland-place. Improvements in hydrostatic engines.

734 J. A. Lee, Lydney, Gloucestershire. Improvements in machinery for cutting and reducing wood, adapted especially to prepare it for the preparation of paper fibre therefrom.

735 I. W. Nasarow, Finsbury-square. Improvements in the manufacture of iron and steel. (A communication.)

Dated March 4, 1868.

737 S. Jefferies, Dudbridge Hill, Stroud, Gloucestershire, engineer. Improvements in, and apparatus for, securing, adjusting, and arranging cords, ropes, and chains employed for raising and lowering venetian blinds, curtains, windows, shutters, and other analogous purposes.

739 A. Cole, Erith, Kent, merchant's clerk, and J. Carter, Bexley Heath, Kent. Improvements in, and applicable to, lamps for burning petroleum, hydrocarbon, and other oils.

740 E. Clifton, Bradford, Yorkshire, ironmonger. Improvements in adjustable door handles.

742 H. E. Smith, Hereford, engineer. Improvements in the hauling or winding gear of engines used for agricultural and other purposes.

743 A. M. Clark, Chancery-lane. Improvements in paving roads, streets, or ways. (A communication.)

744 W. K. Stuart, Glasgow, chemist. Improvements in arrangements and apparatus for dealing with and utilizing sewage.

745 J. G. Kincaid, Greenock, Renfrewshire, engineer. Improvements in twin-screw propelling apparatus.

746 W. and T. Mitchell, Stacksteads, Lancashire. Certain improvements in the manufacture of felt carpeting, and in apparatus to be employed therein.

748 C. Scholefield, Beverley, Yorkshire, engineer. An improved method of hanging or suspending window sashes.

749 J. Askew, Charles-street, Hampstead-road, engineer. Improvements in the construction of a hook and eye for fastening together the ends of window blind cords, and cords for hanging pictures.

750 J. Brigham and R. Bickerton, Berwick-upon-Tweed, agricultural implement makers. Improvements in reaping and mowing machines or harvesting machines.

751 L. Cole, manufacturer, and A. Maxfield, machinist, Birmingham. Improvements in sewing machines.

752 C. R. Rockley, Cannon-street, St. Paul's, City. Improvements in pipes for smoking tobacco.

Dated March 5, 1868.

755 F. T. Baker, Fleet-street, City, gunmaker. Improvements in the manufacture of cartridge cases.

756 J. J. F. Stevens, Southwark, Surrey, engineer. Improvements in the construction of railway and other signal apparatus.

757 J. Hammersley, Spencer-street, Clerkenwell, chronometer manufacturer. Improvements in the construction of marine chronometer boxes.

758 H. A. Dufrene, South-street, Finsbury. Improvements in covers or capsules for jars, pots, and other vessels. (A communication.)

759 W. Hunt, Castleford, Yorkshire, manufacturing chemist. Improvements in treating certain compounds of copper and iron, and in utilizing residual products obtained therefrom.

761 W. E. Gedge, Wellington-street, Strand. Improvements in steam engines. (A communication.)

762 J. Westray and J. Forster, Barrow-in-Furness, Lancashire, engineers. Improvements in machines for drilling and boring.

763 J. Hartshorn, Nottinghamshire. Improvements in the manufacture of lace in twist lace machines.

764 J. L. Clark, Beechmont, Sydenham Hill, Surrey. Improvements in differential galvanometers.

765 C. H. Gould, Birmingham. Improvements in single or combined rivets for riveting the soles of boots and shoes, and in the machinery for manufacturing them; likewise in the means for grooving boot and shoe soles for receiving such improved rivets, and also in the tools used for applying the same.

767 H. Drake, Chef of the Carlton Club, Pall Mall. Improvements in the preparation of essences suitable for soups.

769 A. V. Newton, Chancery-lane. Improved apparatus for cultivating land and sowing seed. (A communication.)

770 A. M. Clark, Chancery-lane. Improvements in steam pumps. (A communication.)

771 J. Dickson, Belfast, mill mechanic. Improvements in lubricators or tallow feeders.

Dated March 6, 1867.

773 I. L. Pulvermacher, Regent-street, electrical engineer. Improvements in apparatus or means for producing, applying, and ascertaining the power of electric currents.

774 J. Brinsmead, Wigmore-street, Middlesex, pianoforte manufacturer. Improvements in the construction of pianofortes.

775 J. M. Stanley, East Parade, Rhyl, Flintshire, ironfounder. Improvements in the construction of furnaces.

776 T. Whittaker, Manchester. Certain improvements in the preparation of paper to be employed in the manufacture of waterproof paper.

778 G. Hauxwell, Durham, engineer and millwright, and J. Ryder, Sunderland, Durham, miller. Improvements in preparing hard foreign wheat for manufacturing into flour, and in apparatus to be employed for such purpose.

780 J. Watson, Durham, manufacturing chemist. Improvements in blast furnaces, and in obtaining a hot blast for the same.

782 T. Atkins, Fleet-street, City. Improvements in apparatus for extinguishing fire.

784 J. Parker, Lilford-road, Camberwell. Further improvements in apparatus for obtaining motive power for engines by a combination of steam and air, and for the prevention of racing in steam and air marine engines, and for a condenser applicable to steam and air engines, and for other purposes.

786 J. G. Tongue, Southampton-buildings, Chancery-lane. Improvements in the construction of steam boilers. (A communication.)

Dated March 7, 1868.

788 J. Campbell, Founder's-court, Lothbury, City, engineer. Improvements in floating docks.

790 R. Leake, Manchester, and R. Platts, eccentric engraver. Improvements in machinery for etching or engraving rollers for printing.

792 H. Simmonds, Mark-lane, City. Improvements in machines for hulling or decorticating cotton or other like seed. (A communication.)

794 A. C. Kirk, Glasgow, engineer. Improvements in treating cast iron.

796 R. Tooth, Fenchurch-street, City. Improvements in the evaporation of liquids, and in apparatus to be employed therein.

798 J. Thompson, Manor House, Camberwell-road, and J. Thompson, Camberwell Green. Improvements in fixing door and other knobs, and in connecting knobs to spindles.

802 E. Casper, Cannon-street, City, merchant. An improved apparatus for raising and forcing liquids, more especially designed for supplying water to steam boilers. (A communication.)

Dated March 9, 1868.

804 H. M. Lee, Cross-street, Manchester, jeweller. Improvements in cases employed to contain visiting or address cards.

808 C. D. Abel, Southampton-buildings, Chancery-lane. Improvements in screw bolts and nuts for securing fish plates and other objects. (A communication.)

810 A. F. Baird, Pimlico, Lieut.-Col. in the Bengal Staff Corps. Improvements in earth closets, applicable also to urinals.

812 H. Willis, Rochester-terrace, Camden-road, organ builder. Improvements in the construction of organs.

814 E. Morewood, Cheam, Surrey. Improvements in coating metal plates, and in apparatus used therein.

816 A. M. Clark, Chancery-lane. Improvements in the means and apparatus employed for freezing liquids. (A communication.)

PATENTS APPLIED FOR WITH COMPLETE SPECIFICATIONS.

Dated March 11, 1868.

841 P. Lennox, Lynn, Essex. An improved machine for beaming hides or skins, as well as for scouring and sleeking leather.

Dated March 13, 1868.

865 C. R. Broadbent, Southampton-buildings, Chancery-lane, doctor of medicine. Improvements in the manufacture of hats, bonnets, and other similar articles.

Dated March 16, 1868.

886 H. A. Bonneville, Sackville-street, Piccadilly. Improvements in jacquard looms. (A communication.)

887 H. A. Bonneville, Sackville-street, Piccadilly. Improvements in the permanent way of railroads. (A communication.)

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the "London Gazette," March 24, 1868.

3181 S. Buxton and W. Gardam. Safety lamps for mines.

3185 W. R. Lake. Armour for war vessels. (A communication.)

3197 R. P. Faucheux. Tobacco pouches.

3202 M. B. Westhead and R. Smith. Arranging tapes in boxes.

3204 L. A. Badin. Bungs for casks.

3210 F. Andrew and E. Whittaker. Rollers for printing colours on yarns.

3220 P. E. Bland. Machinery for making bricks.

3225 R. Harrison. Cocks or taps.

3234 P. M. Parsons. Manufacture of artificial granite.

3240 L. B. Bertram. Tobacco pipes.

3243 A. M. Clark. Refining copper. (A communication.)

3244 J. Templeman. Manufacturing fire-lighters.

3250 C. E. Brooman. Ornamenting bottles. (A communication.)

3255 R. W. Pearce. Apparatus for developing the power of pianofortes.

3257 J. M. Napier. Machines for printing calico.

3259 W. Bailey. System of ornamenting paper-hangings.

3260 J. G. Tongue. Process for ageing and refining wines. (A communication.)

3264 C. E. Brooman. Process of manufacturing metal direct from the ore. (A communication.)

3272 T. Wood. Lamps.

3273 R. Ward and T. Travis. Manufacturing woven fabrics.

3283 S. Coulson. Manufacturing coffins.

3290 W. Brewster. Apparatus for boiling clothes. (A communication.)

3294 G. F. Redfern. Paving. (A communication.)

3307 V. Burchell. Machinery for manufacturing soda water.

3314 G. D. Hughes. Apparatus for consuming smoke.

3223 W. Mort. Preserving meat. (A communication.)

3349 J. H. Johnson. Treating rabbit skins. (A communication.)

3354 C. Coates. Machinery for cutting stone.

3355 J. H. Johnson. Construction of piles. (A communication.)

3357 A. M. Clark. Ornamenting gauze. (A communication.)

3368 W. Palmer. Horses' shoes.

3386 T. B. Jordan and J. Darlington. Machinery for boring rocks.

3393 J. H. Johnson. Machinery for grinding bones. (A communication.)

3419 W. Schofield. Preparing cloth.

3431 S. Vaile. Labels.

3489 W. Clissold. Machinery for preparing fibrous substances for spinning.

3507 W. Palliser. Ordnance.

3563 E. H. Bentall. Apparatus for controlling the draught of water from constant supply pipes.

3588 S. Marsters. Machine for rubbing ropes.

3591 W. E. Newton. Apparatus for manufacturing tinned leaden pipes. (A communication.)

3647 C. J. Adams. Self-acting fire alarm.

3670 B. and J. B. Bowen. Manufacture of gloves.

202 A. V. Newton. Sewing machines. (A communication.)

224 C. R. Broadbent. Manufacturing shoes.

281 W. E. Newton. Machinery for forming hat bodies. (A communication.)

369 J. Offord and S. W. Hale. Carriages.

481 J. G. Willans. Manufacturing iron and steel.

566 P. N. Goux. Disinfecting human excreta.

571 W. E. Newton. Mechanical movements to be used in clocks and watches. (A communication.)

586 A. V. Newton. Reaping machines. (A communication.)

629 J. M'Leod. Apparatus for washing yarns.

685 W. E. Newton. Drying felted goods. (A communication.)

726 J. Dewar. Preserving blood.

746 W. and T. Mitchell. Manufacture of felt carpeting.

778 G. Hauxwell and J. Ryder. Preparing hard foreign wheat for manufacturing into flour.

808 C. D. Abel. Screw bolts. (A communication.)

841 P. Lennox. Machine for beaming hides.

865 C. R. Broadbent. Hats.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list, who have given notice of their intention to proceed, within twenty-one days from the date of the "Gazette" in which the notice appears, by leaving at the Commissioners' office, particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed March 20, 1868.

2656 G. E. Marchisio	2715 J. Jameson
2657 J. Hargreaves	2717 E. T. and C. Horsley
2662 B. and A. B. Blackburn	2719 J. Jameson
2665 A. Mackenzie and S. Robinson	2733 J. and J. A. Huggett
2668 A. Aitchison and H. J. Grantham	2753 J. Dewar
2687 W. Winter	2800 R. Hattersley
2688 G. Batcheldor	2888 W. R. Lake
2690 J. H. Brown	2907 W. B. Adams
2692 T. H. Williams	3178 W. Thompson
2701 W. Woodcock	3697 J. E. Gowen
	186 J. Carr and C. Lucop
	345 H. M. Ragland
	283 F. N. Clerk

Sealed March 24, 1868.

2703 A. Rooker	2851 G. Twigg
2706 J. and J. Kirk	2854 J. Withinshaw and J. E. Baker
2713 J., B., and R. Wood	2889 M. A. F. Mennons
2714 A. Morrall	2903 E. Gesaner
2716 G. Wilkinson	2992 J. Mitchell
2731 L. de la Peyrouse	3424 J. Hadley
2736 H. A. Bonneville	3632 J. Hadley
2743 J. Elder	149 J. A. Jones
2763 W. Mitchell	161 S. and E. Burrows
2796 J. Offord	
2838 H. Wallwork	

PATENTS ON WHICH THE STAMP DUTY OF £50 HAS BEEN PAID.

734 S. B. Boulton	799 W. J. Coleman
750 J. Bullough	808 G. E. Donisthorpe
753 A. V. Newton	815 D. Mackenzie
759 E. Pilling and J. Harper	818 A. B. Baron von Rathen

THE

MECHANICS' MAGAZINE.

LONDON: FRIDAY, APRIL 3, 1868.

COMPOSITE SHIPS.

ABOUT four years since we placed before our readers those facts of interest and importance with which we were at that time cognizant in reference to the construction of composite ships; and, as with England, beyond any other nation, the efficiency and economy of our mercantile marine are of paramount importance, we now revert to that subject. In dealing with vessels of this description—or, indeed, with vessels of any other character that may hereafter be projected—their standard of excellence must necessarily be arrived at by comparison with the existing kinds of vessels they are required or expected to supersede. Commercially, these latter are of two kinds—firstly, those with hulls composed entirely of wood; and, secondly, those with hulls composed entirely of iron. We believe we shall run no risk of contradiction when we state that the old-fashioned wood merchant vessels are doomed in the race of competition now in progress, referring as we do, of course, to the entire mercantile navy, steamers and sailing vessels, required for our ever extending commerce. This point granted, it is only necessary for us to deal with the composite as compared with the iron ship, and it is to this that we invite attention. In dealing with this question, the term efficient must be allowed a more extended meaning than is usually accorded it. Every shipowner is aware that he may be supplied with two vessels of similar sailing and carrying qualities, each at the time deemed "efficient" for a given trade, whilst the cost of the one may be nearly double that of the other, and as economy in these matters is, and probably always will be, the great desideratum of the capitalist, he will naturally invest in that description of property which promises, after all probable contingencies have been duly weighed, the greatest return for his outlay.

The chief advantages of an iron ship are, firstly, great general strength of hull; secondly, small liability to decay; and, thirdly, cheapness of construction. The chief disadvantages are local weakness and liability of the bottom to fouling—the latter being by far the greater barrier to the rapid development of iron ship building. The composite system of construction is susceptible of many ingenious combinations, and in its earlier stages many and varied were the plans adopted. To this fact, to a great extent, must be attributed the greater cost of those vessels, and hence, at one time, the comparatively small demand for them. The one great feature which gave these vessels an ascendancy over those built of iron was the practicability of sheathing their bottoms with yellow metal or copper sheathing, thus enabling them to prosecute long voyages under the most favourable conditions for speed. No one of course doubted their success in this respect, since no new principle was involved in the trial; but the rapid passages made by many of them in the China trade confirmed the most sanguine expectations. But let us see what experience and more mature study have led, and are still leading us, to in the mode of combination; for if it be demonstrated that speed and quick passages are compatible with seaworthiness and durability, it is just possible that a small additional first outlay may eventually be much more than counterbalanced.

Want of space prevents us here entering into the details of the many methods of early construction. It will be sufficient for us to state, broadly, that three modes of combination at first prevailed, which we may briefly describe, or rather classify, as follows:—Firstly, that in which one thickness of planking was employed fastened by iron nut-and-screw bolts; secondly, that in which one thickness of planking was employed fastened by yellow metal nut-and-screw bolts; and, thirdly, that in which two thicknesses of planking were employed—in the last-named case the first or inner skin being fastened through the frames by iron nut-and-screw bolts, and the outer or second skin being fastened to the inner skin alone by bolts of yellow metal or copper driven through and clenched upon rings upon it. With reference to the first-mentioned mode of combination it will by many be known that the heads of the bolts were sunk about 1½in. within the outside surface of the planking, and it was sought to protect them from the deleterious influence of the metal sheathing by means of wooden plugs driven upon them dipped into or covered with white lead or some glutinous composition, and it was asserted by many at the time that the experiment would prove unsuccessful. Experience has proved the truth of this prophecy, for, in several vessels, on examination of the bolts on their removal after three or four years' service, their heads, and necks under the heads, have been found to be considerably affected, the water having doubtless been the constant medium of communication from a very early period after their immersion. These facts, then, would appear to dispose of the principle of iron fastening, inasmuch as concerns those portions of the vessel under, or immediately contiguous to, the yellow metal sheathing.

We now come to the consideration of the class previously designated as Class 2, or that method of construction in which one thickness of planking is fastened with screw-bolts of yellow metal, the nuts of the same material being "set up" upon the inside of the iron frames. We have been reliably informed that these vessels quite realize the expectations formed of them, the iron to be acted upon in these cases being the internal frames or ribs, which, from the absence of the water, remain unimpaired. This exemption, however, would probably not extend to the frames and floor-plates situate in the vessel's bottom were it not for the fact that they are covered with cement to the upper part of the bilges, as are the bottoms of iron vessels. From enquiries we have recently instituted, we learn that this is the type of composite vessels now being adopted, since amongst not less than two dozen, representing a tonnage of upwards of 15,000 tons, now in course of construction at a few of our principal outports (not a bad omen in the present depressed condition of the shipbuilding trade) not a single vessel having two thicknesses of planking is reported as under construction. It should be observed that the yellow metal fastenings, for economy's sake, are not carried above a height where the galvanized iron bolts may be employed with safety as to their proximity to the metal sheathing, and this height is defined to be at a distance of about one-fifth of the vessel's depth of hold set down from the upper deck. From the above facts there can be but little doubt that the extra expense attaching to vessels with two thicknesses of planking is the principal cause for their not being adopted, since it is not by any means the first cost alone that has to be considered, but the many subsequent outlays attending repairs which may be rendered necessary from groundings, collisions, and other contingencies.

Penning the word "collisions" reminds us of a matter in connection with these vessels which we deem of great importance, but which we fear is seldom—if ever—considered, namely, a forward or collision bulkhead. When we remember that the same facilities for their erection exist in these as in iron ships, and bearing in mind the insignificance of the expense as compared with the immense service to be expected of them, we think that no vessel should be considered complete without one. We shall of course be glad to learn that our fears in this respect are without foundation, but we remember going carefully through a long list of suggestions for the construction and classification of composite ships, prepared by the Committee of Lloyd's in the year 1867, and although every page of that list bore evidence of careful research and study, yet we believe that not in a single instance was a bulkhead mentioned. We cannot afford the space necessary for the mere mention of the many instances of their efficacy; but we cannot forbear to instance the collision between the iron steamers "Eider" and "Curfew" off Souter Point, as recently as the 14th of February last. In this case the vessels came fairly end on to each other, and, although the crash was terrific, and the damage great, yet the bulkheads were the means of the preservation of the two ships, and which are now probably running as usual, instead of lying at the bottom of the sea.

If it came within the compass of this article we should like to draw a comparison, as far as is practicable, between the two descriptions of vessels—the composite and the iron—and to show the comparative sectional areas of those portions of their structure which assimilate to each other, for we find that a striking similitude of sectional area exists in all the principal parts of the frames proper, by which we mean the frames, reverse frames, floor-plates, keelsons, beams, stringers and deck stringers, tie-plates, &c. It is true, indeed, that the frames of a composite vessel are spaced somewhat closer than the frames of an iron one, doubtless with the view of contracting the spaces of the plank fastenings in consideration of the caulking, but this addition, with the outside sheer, bilge, and intermediate strakes of plating, make up the chief difference between the two vessels—excepting, of course, that of the planking in the one case, and the plating in the other. It remains, then, to determine which of the two it is desirable to adopt. This will be settled, doubtless, in favour of iron wherever the exigencies of the trade will admit of the frequent cleaning of the bottom; but in the absence of these opportunities, and where facilities do not exist, a copper or metal-sheathed bottom will be adopted, and we doubt not that the composition principle of construction will steadily gain favour as its many advantages become more generally known.

PRESSURE OF THE WIND.

AS the weight of a bridge tends to counteract the momentum, or *vis viva* of a rolling load, so does that of a roof act as a resisting agent against the force of the wind, and were it not that engineering skill and financial economy forbid the adoption of unnecessarily heavy structures, the elements of mass and weight would be more prominently conspicuous in their details. We have now arrived at a time when the theory of the strains, whether due to a live or dead load, brought upon the various parts of bridges and roofs is thoroughly understood. Their direction and amount can be rigidly investigated and accurately ascertained, and instead of, as formerly, combating their action by increasing the total insistent weight of the structure, that is, by mere brute force, the aid of science is brought to bear upon the subject. By its unerring assistance, the requisite degree of strength is bestowed upon each individual member; some are stronger, some weaker than others, but every one receives its proper share of material and performs its own duty, instead of contributing to the stability of the erection in an uncertain, vague, and unsatisfactory manner. Previously to the introduction of wrought iron as a constructive material, weight and strength were synonymous terms, and it was not until the rapid spread

Digitized by Google

of steam locomotion necessitated the employment of bridges exceeding in size all existing examples, that it became apparent that the "ponderous principle" must be abandoned. One reason why mass was so much relied upon in earlier times, and regarded as identical with strength, was that the arch was the only known method of spanning any intervening space, and in this form alone the weight may be increased enormously, before it begins to act in a detrimental manner. In the horizontal, catinarian, and other systems, every ounce of weight is a direct element, and constitutes a definite proportion of the breaking weight of the structure. The limit, therefore, at which a bridge designed upon any of the above principles would give way under the action of its own dead weight is soon arrived at, since, while its powers of resistance increase as the square, the force tending to break it augments as the cube. This fact should be borne in mind by those who are advocates for bridges of spans so stupendous as a couple of thousand feet or more.

The pressure of the wind has been variously stated, ranging from 10lb. to 40lb. per square foot. At the Menai bridge the maximum observed was equal to the latter amount, but a pressure so high as 65lb. per same unit of area has been registered by an undoubted authority. From 28lb. to 30lb. per square foot is an ample margin to assume in the case of roofs and all similar buildings. There is perhaps no principle of bridge construction in which a superabundance of dead weight would be more injurious than in the suspension. To a certain extent, it would act antagonistically to a moving load, but if we suppose it to be once set in motion to become itself part of the moving load, it would tend most materially to the downfall of the bridge, and this is what really occurs whenever a suspension bridge is in a state of oscillation. Hence the difficulty of applying this principle to railway purposes. A strong gale of wind was quite sufficient to actually break down some of the earlier suspension bridges, and throw them into a state of undulation to the extent of four and five feet. Bracing in a scientific and judicious manner has been found to be a partial remedy, but it yet remains an unsolved problem how far this remedy can be applied *in extenso*. The question of the pressure of the wind upon a large tubular bridge was entertained at length previously to the erection of that over the Menai Straits. The engineer considered it as a trifle, and not likely to be felt by the bridge, instancing the case of a chimney, which, if properly constructed, rarely suffers from this cause. Nevertheless, chimneys built in the best manner have frequently succumbed to the violence of the hurricane and the fury of the storm.

There is a difference to be noted in the distribution of the wind pressure upon a tubular girder and a roof. In the one it is scarcely necessary to regard the action of the force in any but a lateral direction, whilst in the other it must be considered as exerting a strain in every direction. Although the force of the wind has not been proved to do any injury to bridges even in the most elevated positions, it has produced some serious results with respect to the passage of trains. No less than four accidents have occurred upon the Midland Railway of France, and the company in consequence caused some statistical information to be drawn up which is of much interest. One of the trains which suffered from the cause alluded to, consisted of seven carriages, and the accident took place at a time when it was running over a straight piece of line at a rate of about twenty miles per hour. The wind was a strong north-wester, and its direction was nearly perpendicular to the line of route. Two of the third-class carriages were overturned. The weight of one was almost exactly seven tons; its moment of resistance five tons, the surface exposed to the force of the wind 150 square feet, and the lateral pressure required for its equilibrium 39lb. per square foot. As the carriages were overturned, it is clear that the pressure per square foot was greater than the above quantity, and it is unfortunate that means were not taken to register its actual intensity. At the same time it was ascertained that the force did not exceed a certain limit, since a heavier description of carriage was not overturned. This was a luggage van, of which the weight was rather over 7¼ tons, the moment of resistance above that of the two that suffered overturning, the surface exposed to the pressure considerably less, being, instead of 150, only 110 square feet, and the equilibratory pressure 62lb. per square foot. Had the force of the wind exceeded this latter quantity, the van would have been also overturned. The limits, therefore, of the pressure exerted may be considered as 39 and 62, or, in round numbers, between 40lb. and 60lb. per square foot, which is a very close approximation to those already mentioned at the commencement of the present article. It would appear from these statistics, that when the pressure of the wind exceeds 40lb. per square foot, some of the carriages upon the French railways are liable, in nautical language, to be capsized. This dangerous liability would be farther increased on the supposition that the train was running round a sharp curve, with the wind acting in a direction from the centre to the circumference of the arc. An addition might thus be made towards the centrifugal force, which might prove too much for the ordinary precautions adopted upon the curved portions of a line.

EFFECTS OF CARBON ON THE ELECTRO-DEPOSITION OF SILVER.

We have just witnessed a series of experiments on the deposition of silver from cyanide solutions, with a view to ascertain the reason of the various textures of the deposits under different conditions. The texture of the silver deposited from a new and pure solution of cyanide of silver in a solution of cyanide of potassium is of a soft silky appearance and of a pearly whiteness, having a slight rosy reflection. If this appearance were only permanent it would render articles so coated very beautiful, but it speedily vanishes on being exposed to the air. Of course if this appearance were not so evanescent, still portions of articles so coated would be polished, but its evanescence necessitates the polishing of all articles so coated and on the whole of them. This was felt to be a great inconvenience, consuming so much time, and it was felt that it might be possible to deposit the silver in a polished state,—first, because it was known that gilding could be done with a polished surface; moreover, it was seen that on certain parts of certain articles there were deposited streaks of polished silver; for example, above any small hole or small projecting point there would be a streak of polished metal, but no one could surmise the reason of it.

We think this might have been seen if the nature of the solution and the laws of electric action had been considered; but perhaps neither the one nor the other was clearly understood by the operators; at any rate, the thing was not reasoned about but groped for, and by chance the discovery fell to an operator who was experimenting for another purpose. Elastic moulds were being used for the solid deposition of silver, and it was found that around these moulds the articles received a bright deposit, and it was naturally concluded that it was something in the moulds which produced it. This could be neither the gutta-percha nor the india-rubber of which the moulds were made, so that it was clear that it must be the solvent of these articles, which was bisulphide of carbon. Bisulphide of carbon being tried it was found to produce the desired result. Since then, what is called brightening solution has been used by most electro-platers. This is made by adding periodically to the ordinary cyanide, solution, in the proportion of a few drops of bisulphide of carbon to each gallon; but it is found that this solution is difficult to manage. It is found that dark streaks occur frequently where bright ones occurred in the ordinary solution, and this has not been well understood, or, in fact, the reason of it has not been understood at all. Besides this, opaque white patches will occur, or the whole surface of the article will become opaque white, the solution appearing to be most capricious in its action: consequently, other carbides have been tried,—for example, different hydrocarbides; but these have not been found to work so well as the bisulphide, so that this is still retained by those who use the brightening solution.

Now we feel quite convinced, from the experiments we have made in this matter, that all these inconveniences are easily explained and avoided. It is the carbon in these solutions that is the cause of the bright deposit, not only in the carbide solutions, but in ordinary solution where bright streaks occur. Wherever there are asperities on an article those will receive a greater amount of electricity than other parts, and if the general current be such that it is just below the point of decomposition of the solution, at these points it will commence to decompose it, and carbon will be set at liberty. In the carbide solution the black streaks occur from the same cause. The bisulphide solution is decomposed on being added to the cyanide, a black cloud of carbon being produced, which, on being stirred in, is held in suspension, and the sulphur unites with the potash of the solution; this, on a strong current of electricity being passed, is decomposed at the afore-mentioned asperities, and sulphide of silver is produced, which is black. Now, sulphur is the one thing that we have to protect silver from, being the thing that most readily tarnishes silver; therefore, a sulphocarbide should not be used, or, if it be, great care should be taken in the management of the battery. Too great an intensity decomposes the solution and also produces an opaque white deposit.

But the great question to be solved is, in what way does carbon produce such a brilliant and dense deposit? In appearance it is like fused silver, but denser than rolled silver. Does carbon unite with the silver as it does with iron to produce steel? If it does, it must be in almost infinitesimal quantities, for two drops of the bisulphide to the gallon of the normal solution is sufficient to produce the bright deposit. It cannot be due to the electrical current, for the same current in an ordinary solution will not do it. We are of opinion that the carbon unites with the silver, and produces a body somewhat analogous to steel; but it will require the delicate chemical manipulation of M. Stas to detect the carbon or to prove its absence. However, the valuable fact remains, that silver can be electro-deposited in a harder and more durable state by means of a soluble carbide than it can be produced in any other way, and with care can be as easily deposited as from any other solution.

THE SILVER COINAGE OF GREAT BRITAIN.

It may be permitted us to hope that out of the deliberations of the International Coinage Commission, now holding its sittings in Whitehall, some definite proposition may spring for the reformation of the coinage of this country. We have faith in the members of that commission, for all of them are eminently qualified by talent and by experience for executing the task they have undertaken to perform. They are *bonâ fide* work-

Digitized by Google

ing men, in the highest sense of the term, and are well calculated, therefore, to initiate practical improvements rather than to offer fanciful and theoretical suggestions. It is perhaps too much to expect that the commissioners will go so far as to recommend the decimalization of the coinage off-hand, although that is "a consummation most devoutly to be wished," but it is not to be doubted that in the abstract they will favour that conclusion. The usefulness of the coinage is undoubtedly the primary and most important consideration, and when the word "usefulness" is employed, it is here meant to imply the fitness of coins composing it for the purpose especially, of making small payments with exactitude, and with as little inconvenience as possible to the payer and the payee. The one great point to be regarded in altering a coinage is, therefore, how to add to its usefulness. The making a change for the mere sake of change, it is needless to say, would be a proceeding of a very unwise character. In this—as, indeed, in all other countries—a very large proportion of the retail purchases are made for the coin's worth, or the articles are made to be sold for the known individual coins in circulation. The adaptability, then, of coins for making such purchases is the great test of the merit or demerit of any system of coinage. Of course, it is of consequence also that the question of account keeping should not be disregarded in the arrangement of the various denominative coins. This affects the affluent and the educated rather than the poor and the ignorant classes of society, and is really of secondary moment. To facilitate the distribution of commodities in retail markets and retail shops, is the one great object to be kept in view by those who attempt a salutary reformation of the coinage. That the introduction of a decimal system of currency would answer this vital purpose more effectually than any other mode of reforming the coinage which can be suggested is, we think, indisputable. It would certainly facilitate commercial transactions with other countries to a greater extent than the introduction of only one or two coins of assimilation, as has been suggested in some quarters.

The question of decimalization, however, we leave for the present in the hands of the Commission, and shall venture to offer a few remarks upon the existing silver coinage of Great Britain. This, there can be no hesitation in saying, is in every way in an unsatisfactory state. One of the first steps taken with a view to the improvement of the silver coinage, whatever may be ultimately done in the way of decimalization, should be the withdrawal from circulation of all crowns, half-crowns, and fourpenny pieces. They have long since been doomed to a gradual process of extinction, and numbers of them find their way annually to their birthplace and their grave—the crucibles of the Royal Mint. This is not enough. They linger on the stage when their parts have been already played out, and interfere injuriously for the public interests with their fellow performers. A very large proportion of the crowns and half-crowns have been in circulation ever since the great re-coinage of silver in 1816-17. They have consequently deteriorated in appearance and lost weight by attrition to such an extent as to render them unfit for service, and in every way discreditable specimens of British mintage. Beyond these patent and notorious defects, there exists another evil which is perhaps of more serious moment. The smooth-faced crowns and half-crowns present almost irresistible claims upon the attention of professional manufacturers of spurious money. Such pieces may be imitated in base metal by even "'prentice hands" engaged in the nefarious trade. There are no artistic or fine lines to copy, and plaster of Paris moulds and pewter pots yield excellent copies of the 'erstwhile beautiful examples of the engraver's skill.

It is understood by those who are in a position to know the fact that many thousands—and, it may be, hundreds of thousands—of counterfeit crowns and half-crowns are now eddying along the channels or lurking in the creeks of general circulation. The palpable remedy for these defects is the speedy recall of all the genuine coins, their transmission to the Mint, and their conversion into coins of existing and not of extinct species. The collection of the condemned pieces might be made simultaneously throughout the country by the assistance of provincial banks, the authorities of which might previously be supplied with florins, shillings, and sixpences of recent mintage for exchange. The loss of weight contingent upon re-melting and re-casting the obsolete coins might well fall upon the national treasury, the public having had all the advantages of their long existence and contributed to their deterioration. All that is needed for giving effect to our suggestion is the issue of a Royal Proclamation and the completion of a few preliminary and minor arrangements. The fourpenny pieces, of which there are comparatively few in circulation, might be recalled and converted forthwith into threepennies (which is about their intrinsic value), and thus another source of annoyance would be got rid of.

It is said that the Mint stamping presses are only working half-time at present, and that the Mint workmen are consequently receiving only half-pay. The coinage of the three denominations of coins in question would correct both these evils and confer besides a benefit upon the whole community. It would, in fact, form a fitting prelude to whatsoever change may be finally decided upon as to the coinage of the country generally. It is intended that the subject of the silver coinage shall ere long be reverted to again in these columns, for it is impossible in the limits of one article to indicate all the improvements which ought to be carried into effect in regard to it. It was the privilege of this journal to suggest originally the supercession of the old copper coin by the introduction of the bronze money which now so admirably does duty in its stead. It shall be from no fault of ours if a similar and far more important improvement be not made with respect to the silver coinage of the British Empire.

FEATS IN TELEGRAPHY.

THE recent performances of the electric telegraph are interesting, and serve to mark the great progress which has been made in the art of electrical communication. Our readers remember that four weeks since we noticed the banquet given by Mr. Cyrus W. Field to celebrate the fourteenth anniversary of the day on which the New York, Newfoundland, and London Telegraph Company was formed. We then referred to the circumstance that during the evening telegrams were sent from the room to various parts of the American continent, replies being received with wonderful rapidity. We now give the interesting details of these operations. The messages were delivered at their respective addresses, and the replies to them were received back in the room in the following periods:—From the President at Washington, 2hr. 10min.; from Mr. Seward at Washington, 2hr. 25min.; from several persons in and near New York, average 1hr. 45min.; from the Governor of Cuba, who apologized for the delay caused by his residing at a distance from Havannah, 2hr. 24min.; from the Governor of Newfoundland, at St. John's, 38min.; and from Heart's Content, Newfoundland, 6min. These performances, however, are thrown into the shade by an ordinary message sent from London to San Francisco on February 1 last, and which is thus recorded by Mr. Latimer Clark. The wires in America were joined up for experiment from Heart's Content to California, and the message was sent from Valentia at 21 minutes past 7 in the morning,; the acknowledgment of its receipt was received back in Valentia at 23 minutes past 7, the whole operation having only occupied two minutes the distance travelled was about 14,000; miles, and the message arrived, accordiug to San Francisco time, at 20 minutes past 11 on the evening of January 31, or the day preceding that on which it left England. It is well, adds Mr. Clark, to enjoy these surprises while we can, for they will soon cease to surprise. The truth is, telegraphy has outlived the troubles and misfortunes of its infancy, and is rapidly taking its place among the most perfectly understood of the arts. As it is a very remunerative one, we shall soon learn to regard an instantaneous means of communication with the whole globe as a matter of mere ordinary necessity.

ARTIFICIAL STONE SCREENS FOR THE NEW GOVERNMENT OFFICES.

THE adage, so often written on copy-books at school, that "Perseverance overcomes many difficulties," has found a notable illustration in the case of Mr. Frederick Ransome and his artificial stone; and it would have been a cruel reverse had the adage failed in his case. There could scarcely be a more convincing proof of the simple justice of patent right than this, in which so much time, toil, money, and vital energy, have been expended in the course of a long race from the starting post to the goal, a race in which, in the absence of patent right, an unprincipled interloper might have entered the course in the run home, and have beaten the better horse by a neck. We have from time to time had to notice the successful application of Mr. Ransome's chemical preservative agents upon numerous public and private buildings. We have also of late recorded the introduction of his artificial stone in foreign parts, and, considering its especial suitability for countries in which good building material and skilled labour are scarce and costly, its gradually extending use is not to be wondered at. Ample and satisfactory testimony as to the results of its adoption is borne by the professional gentlemen, both at home and abroad, under whose direction it is employed. Mr. G. W. Vivian, C.E., for instance, the architect of the Nawab Nazim's palace at Moorshedebad, which covers an area of 420ft. by 130ft., could only choose for his capital, finials, trusses, and other ornamental work, between plaster work and a stone of a costly though very poor quality. He therefore employed the patent stone, and states that "the result has been most satisfactory. The greater portion has been set for two years, subject to alternate rains and heat, such as are only known in a tropical climate; it appears (if possible) better now than when first set; it has the same spontaneous crystalline surface, appears more indurated, and is perfectly free from vegetation and fungus." An equally satisfactory expression of approval is given in an official report by Major Haig, R.E., Superintendent of the Godavery Navigation Works, who states that they have ascertained by actual practice that they can make excellent stone in India by Ransome's process. He writes:—"The principal advantage sought to be derived from this substitution of artificial for natural stone was not cheapness, but the saving of labour, which is effected wherever an article made, or partly made, in England, or elsewhere, can be supplied in lieu of one made upon the spot. The want of labour, the difficulty of collecting it in sufficient quantity, and of retaining it, being the great difficulty we have to contend with on this river, every substitute which machinery, steam, or art, can afford, is a great gain, and in this way I have no doubt that we shall derive valuable assistance from the use of the patent stone." The artifical stone is now being introduced into Ceylon also with great advantage, and our readers may remember

Digitized by Google

that we recently gave a short description of a handsome fountain in this material which was sent out to Hong Kong on Government account.

The highest endorsement of the qualities and capabilities of this remarkable product is probably its intended introduction, by Mr. Digby Wyatt, in conspicuous positions in the new Government Offices, in Downing-street. It is to be used for a pair of enriched truncated pierced screens, in the Renaissance style, which are to enclose the third-floor galleries of the Indian court. This fine quadrangle was designed to have been left open at the top, but is being covered by an elegant roof of wrought iron, which will be filled in with glass throughout. The inner faces of the quadrangle consist of windows almost entirely, excepting only the spaces taken up by the polished granite columns, and the piers which support the superstructure, and spaces at the ends of the quadrangle for eight statues of distinguished Indian governors and heroes, and appropriate historical tableaux in alto relievo. Three galleries cross each end of the court on a level with the respective floors, the two under galleries having balustrades in front. The upper galleries will have the screens referred to, in addition to the balustrade. They have been designed, with exquisite effect, by Mr. Digby Wyatt, and are each 67ft. long by about 6ft. 8in. high, with a mean thickness of about 6in., and will contain about 340 cubic feet. Had the patent stone been liable to warp or shrink it would, of course, have been totally unsuited for ornamental work of such a high character. But it has been abundantly demonstrated to possess incapability of shrinkage, and the absolute rigid retention in every particular of the form in which it leaves the mould. A convincing test as to shrinkage has repeatedly been applied with success, viz., by casting in a block a piece of plate glass cut to parallel lines to preclude the possibility of dovetailing. On breaking the stone after it is thoroughly hardened it is found impossible to extract the glass by any other process than cutting round it to the bottom, which would not be necessary if even the slightest degree of shrinkage took place.

The patterns—to Mr. Wyatt's drawings—and the moulds from them, have been made by the art workmen at the company's works, East Greenwich, and the screens, which are in a forward state, will be finished and fitted as soon as the roof of the quadrangle is covered in, although that need not hinder their erection, the material being invulnerable to atmospheric influences. Builders and contractors are now getting bound doors, sashes, mouldings, and other carpentry goods from Norway and Sweden; they will never need to go so far afield for capitals, finials, trusses, balustrades, or other ornamental work in stone, while the Patent Concrete Stone Company is able, as now, to compete against all comers.

PONTON'S PHOTOGRAPHIC RESEARCHES.*

PROBABLY no branch of physics has so far advanced in its practical applications, and so little progressed as a science, as photography, the philosophy of some of its commonest phenomena being at the present moment as hidden in mystery as when they were first observed by the pioneers of the scientific art. After a collodionized plate covered with iodide or bromide of silver in contact with free nitrate of silver has been exposed in the camera, no change in the film is perceptible to the eye. Yet, when the developer is applied to the plate, out comes the picture on those parts which were exposed to light. Evidently, therefore, the momentary action of light had produced some decided change in the film which the eye could not see, and which, on experiment, it was found that chemical analysis could not detect. Hence the nature of the invisible image has always been a puzzle to photographers.

Recent discoveries in molecular physics, more especially that of atomic motion, were, about eighteen months ago, applied by one of the writers in the photographic journals to the explanation of the phenomena of the invisible photographic image. It was pointed out that if the chemical rays of the spectrum had the power of setting up a motion of separation between the atom of iodine and the atom of silver, the fact would account for most of the observed phenomena of the invisible impression. In the course of the discussion raised by these views, a clerical gentleman living at Clifton pointed out that Mr. Mungo Ponton, F.R.S.E., had published the fact a year or two before, in a book called "The Great Architect." This somewhat remarkable work treats of the construction of the whole of the visible universe, and enters largely into the questions of the size and motions of atoms, also their influence upon the undulations of the hypothetical ether. The author expressed his opinion how vibrations of light act upon a photographic film, as follows:—"In many cases a large portion of the motive energy possessed by the etherial particles, is by them transferred to the ponderable molecules of the bodies with which they are immediately and momentarily associated. Now, the motion thus acquired by the chemical atoms composing any substance, may be such as to give rise to some new arrangement of these among themselves, or, at least, so to modify them as to impart to them a predisposition to enter into new relations or combinations. This effect is most likely to be developed where the atoms are complex, and where the chemical affinity by which they are held together is weak. The transfer of motive energy from the ether to the chemical atoms, then, affords a satisfactory explanation of all the ordinary cases of photography."

Dr. Balfour Stewart, F.R.S., and other philosophers who have studied the subject of molecular physics, also incline to the opinion that when waves of light beat against the photographic film, they set up a motion of separation between the atom of iodine and the atom of silver. The molecules of iodide of silver may thus have the grouping of their atoms changed, or a modification made, which is rendered tangible to our senses by the blackening of the modified molecules under the action of the developer. There is plenty of evidence, as set forth in "Hardwich's Photographic Chemistry," that development is an act of rapid crystallization. The plate is covered with a solution which tends to deposit silver wherever local action begins, and a grain of dust upon the film will provoke a dark deposit of silver all round it, as photographers often learn to their cost. For the same reason, in all probability, the film has a tendency to blacken first wherever light has modified its original molecular structure.

Mr. Ponton's book not only gave the first glimmerings of knowledge as to the nature of the invisible image, but it goes further perhaps than any popularly-written book of the day, into the physical characteristics of the medium which transmits the undulations of light. The author weighs the evidence for and against the alleged storing up of light, as exhibited in some curious experiments by M. Niepce. The latter philosopher first published the fact that if a picture printed upon white paper be exposed for a long time to sunlight, and then be placed in the dark in contact with a sheet of sensitized photographic paper for twenty-four hours, a photographic negative of the engraving is impressed upon the paper. White feathers and marble will act in the same way after exposure to light. If a tin tube, closed at one end, and lined with white paper, have its interior exposed for an hour or more to sunshine, and then be turned mouth downwards upon a sheet of photographic paper in a dark room, an impression of the mouth of the tube will be obtained. Moreover, if the tube be hermetically sealed directly after exposure to light, then kept for a long time, and afterwards placed for twenty-four hours mouth downwards upon a sheet of photographic paper, the latter will be impressed with an image of the mouth of the tube. Mr. Ponton, after briefly describing the above and other experiments of the some kind, points out that the photographic action is not due to "stored-up light." The interposition between the tube and the paper of the thinnest sheet of glass, mica, or any transparent substance impervious to air and moisture, will entirely stop the discolouration of the photographic paper, yet light traverses such films without difficulty. Thin tissue paper, or any very thin porous films, do not arrest the photographic effects: hence there is evidence that the action is a chemical one, and that light liberates traces of ozone or other gases from the actinized paper to produce the observed effects. The necessity of sealing the tube in one of the foregoing experiments shows that the enclosed air has much to do with the results. Since the book by Mr. Ponton was published, M. Niepce de St. Victor has multiplied his illustrations of the apparent persistent action of light, but he has never been able to produce the effect through the thinnest film of glass or mica.

Next, Mr. Ponton criticises Moser's experiments with invisible images. M. Moser discovered that all smooth polished surfaces whatever exhibit a tendency to receive latent images from objects placed in contact, or very near to them, and that these images are capable of being rendered visible by condensing upon the polished surfaces vapours of different kinds. The phenomena much resemble those observed in the Daguerreotype process, and were attributed by Moser to the action of invisible rays. But in this instance, as in the former one, the thinnest transparent films arrested the action, nor could the supposed invisible rays be concentrated by a lens. Moreover, Moser's images were produced as easily in the light as in darkness; for instance, the glass taken out of the frame of an engraving will sometimes show an image of the picture when breathed upon.

The true cause of Moser's images has been very clearly shown by M. Waidelé, who proved that the surfaces of all bodies have a tendency to absorb gas or vapour, and to hold it adhering to them in a very condensed state. Heat, or the near approach of a substance of greater absorbing power, will deprive a polished body more or less of its layer of gas. Moser's images cannot be impressed upon clean plates of metal, which have recently been heated, or polished with fresh charcoal or tripoli, but mere rubbing with the finger, or exposure for a lengthened time to a damp atmosphere, restores the layer of gas, and renders the plate sensitive once more. The thinnest film of grease will produce an image: hence phantom images of printing-ink engravings are readily produced upon polished surfaces.

Of the nature of the action of light upon an iodized plate of polished silver, Mr. Ponton says:—"When an iodized plate is exposed in the camera obscura, the light, wherever it falls upon the plate, throws the molecules of silver into a state of greater or less agitation. This enables the iodine to penetrate further into the silver, and to leave the particles, at the immediate surface, less charged with iodine vapour than before,—some of them being reduced nearly to the pure metallic state. Hence, on the subsequent exposure of the plate to the action of mercurial vapour, these disengaged particles condense the mercury; while the portions of the plate which have escaped the action of light, being already charged with iodine vapour, cannot absorb

* "The Great Architect." By MUNGO PONTON, F.R.S.E. London: Nelson and Sons. Second Edition. 1866.

Digitized by Google

that of mercury. It is to this difference that the development of the image is due."

Mr. Ponton also in his chapters on photography, calls attention to a beautiful example of photographic colouration in Nature. The bell-shaped flower of the Cobœa scandens is of a pale yellowish tint on the first day of its development, but gradually assumes a purple hue, which, on the third day, possesses great depth and beauty, resembling somewhat the dark colour acquired by chloride of silver by the action of the actinic rays. If the flower be kept in the dark, the colouration does not take place.

It would be beyond our province on the present occasion to consider the other subjects included in this interesting book, but those portions were very fully, and, on the whole, favourably reviewed a few months ago, in our contemporary the "Engineer." The book deals with the highest branches of physical science in an intelligent manner, and is throughout a very excellent sample of good clear English composition. The fact that it is published by a firm noted for its religious works, and that it has a title which gives no clue to its scientific character, is perhaps the reason why its existence is comparatively little known, and why the book has been long in coming prominently before the public.

ELECTRICITY AND TELEGRAPHY.

AT a scientific soirée recently held in Washington, Professor Page exhibited one of his small coils illuminating some Geissler vacuum tubes; the electricity used for this purpose was that obtained from a thermo-electric pile of Farmer's, to which we lately called attention.

The Malta and Alexandria cable is still broken down. The "Hawk" steamer, engaged in these repairs, returned to Malta after forty-four days' unsuccessful labour, bad weather prevailing. She was in want of fuel and more cable. She left again on the 25th, to continue the work.

The approaches to Kooria Mooria being rocky, the commander of the "Hydra," surveying vessel, disapproves of it as a station for the projected submarine cable to India. Soundings are to be taken between Aden and Bombay, where the bottom is smooth and undulating.

The bill for the purchase of the telegraphs was read and passed a first time on Wednesday last; it was postponed last week owing to more pressing business. In introducing it, the Chancellor of the Exchequer made mention of the fact that in 1866, in Belgium, one telegram was sent for every thirty-seven letters, whilst in England the proportion was as high as one in 121 letters.

The Swiss papers speak of the trial lately of an electric organ in the church at Sumiswald, in the canton of Berne. In this organ the electrical portion is an independent mechanism, so arranged as to be easily applicable in a short time to any church organ.

M. Becquerel has lately contributed some interesting experiments on the dialysis of electric currents. In passing discharges from an induction coil, between the upper surface of a saline solution and the extremity of a platinum wire fixed at a short distance, the spark was surrounded with a coloured cloud, depending upon the sort of salt experimented with. The saline solutions were placed in a glass tube, so that the discharge passed through their upper surface and the extremity of an insulated platinum wire fixed at a short distance from the liquid, the greatest intensity being obtained when the platinum wire was positive.

A novelty in electric clocks has just been invented by M. L. De Combettes. It consists of a long pendulum, on the lower portion of which is fixed the clock face. The weight is a sort of box containing an electro-magnet and armature, which, on being attracted, disturbs the equilibrium of the pendulum, and consequently gives it motion. The movement of the armature is made to transmit motion to the hands of the clock in a manner somewhat similar to the mechanism of the alphabet dial telegraph instrument. In order to make and break the electric circuit, the movement of the pendulum is made use of, one pole of the battery being connected permanently through the axis of suspension to one end of the electro-magnet, whilst the other pole is connected to a metal plate, against which a point of the pendulum, in connection with the electro-magnet, makes contact at every beat, thus completing the circuit and causing the electro-magnet to attract the armature. It is stated that only a weak battery is required, and that two Daniell's cells will keep it working for several months.

TESTIMONIAL TO MR. ALFRED WILLIAMS.

AS chroniclers of the proceedings of scientific bodies, it is often our pleasing duty to record, amongst others, those of the Society of Engineers. At one time it is its visits to public works or engineering establishments, at another its annual dinner, whilst its ably-written papers are constantly before our readers during the session. It is, however, with much more real pleasure than these things can afford, pleasant as they are, that we now record the presentation of a testimonial, by the members and associates of this Society, to Mr. Alfred Williams, its indefatigable honorary secretary. And this is not mere empty sentiment on our part, but an honest expression of feeling, to which he is entitled for the facilities he has always afforded the scientific press in publishing the valuable papers of the Society; and for the courtesy he has invariably manifested towards ourselves as journalists, in our transactions with him on that head. The pleasing occurrence of which we now write was the occasion of a banquet at the Bridge House Hotel, Londonbridge, on the evening of Friday last. Amongst the gentlemen present there were Capt. Selwyn, R.N., Mr. Thomas Hughes, M.P., Lieut. Woodhouse, Mr. William Wilson, C.E. Mr. Benjamin Fothergill, C.E. The Testimonial Committee consisted of the following members of the Society:—Messrs. William Adams (treasurer), Robert Brass, James Hendry, Baldwin Latham, W. H. Le Feuvre, William Macgeorge, Perry F. Nursey (hon. sec.), Lewis Olrick (chairman), John Pinchbeck, William Roberts, H. P. Stephenson, and George Waller. Besides the above gentlemen, there were also present Messrs. R. M. Ordish, W. T. Carrington, F. W. Bryant, Z. Colburn, J. H. Adams, A. Thorn, E. Field, G. W. Harris (secretary of the Society), David Thompson, as well as a large number of other members and associates of the Society. Mr. Lewis Olrick, the chairman of the Testimonial Committee, presided, and the vice-chairs were occupied by Mr. Baldwin Latham, president of the Society, and Mr. H. P. Stephenson, a past president, and one of the founders of the Society.

After the usual loyal and patriotic toasts had been given and duly honoured, Mr. P. F. Nursey, hon. sec. to the Testimonial Committee, read letters from Messrs. Henry Maudslay, John Penn, E. J. Reed (Chief Constructor of the Navy), William Naylor, James Hendry, and other gentlemen, expressing regret at their inability to be present on the occasion.

The CHAIRMAN then proceeded to present the testimonial, and to propose the toast of the evening—the health of Mr. Alfred Williams. In doing so he referred to the circumstance that Mr. Williams was elected a member of the Society in March, 1855. His abilities soon manifested themselves, for, on the 2nd of April in the same year, he was chosen one of a committee appointed to frame rules for the Society. On December 1, 1856, Mr. Williams was elected honorary secretary of the Society, which position he still continued to hold. When he was appointed, the number of members was 33, at the present moment the number was 486. That increase would give some idea of what Mr. Williams had done for the Society. That number was made up of 14 honorary members, who were some of the most eminent men in the kingdom, 18 life members, 338 annual members, 30 foreign members, and 86 associates. During the whole time of Mr. Williams' tenure of office, which was nearly twelve years, the whole of the Society's affairs had been dependent upon the exertions of the honorary secretary, and by his excellent management, he had facilitated the transaction of the Society's business in every department. He had also bestowed much time in preparing the transactions of the Society for publication. During the time the honorary secretary had been in office, many changes had taken place in the Society, which had constantly increased his labours, especially the alterations to the rules necessary to meet the requirements of a constantly increasing society. As a proof of Mr. Williams's attention to the Society's business, he (the chairman) might mention that during the twelve years he—Mr. Williams—had been in office, he had only been absent twice from either the council meeting or the ordinary meetings of members. In short, Mr. Williams had bee the mainstay of the Society of Engineers at a time when the Society could not stand alone. Without the aid of such an honorary secretary, the Society must certainly have collapsed, and could not have been in existence now. It was, however, possible that even Mr. Williams could be overworked, and it was found last year that the duties thrown upon him were now too heavy for him to continue single-handed. The council therefore engaged the services of a paid secretary, and it was at that time proposed that an appropriate testimonial should be presented to the honorary secretary, not as a recompense for his past services—for recompense would be simply impossible—but as an attempt to prove to him that the members were not ungrateful for all he had done for the Society, and he (the chairman) was sure that in reference to the presentation of that testimonial there was not one dissentient voice. He had now much pleasure in asking Mr. Williams to accept that testimonial from the members and associates of the Society. He had also, in conclusion, to perform the exceedingly pleasing duty of proposing the health of Mr. Williams.

The toast was drunk amidst enthusiastic and prolonged cheering.

The testimonial consisted of a handsome and costly silver tea service and a salver, which bore the following inscription:—"Presented to Alfred Williams, Esq., by the members and associates of the Society of Engineers, as a token of their high estimation of his invaluable services as honorary secretary to the Society, March 27, 1868."

The following address, artistically inscribed on vellum, and neatly framed, accompanied the present:—

TO ALFRED WILLIAMS, ESQ.,

HONORARY SECRETARY TO THE SOCIETY OF ENGINEERS.

It is now about twelve years since you first undertook the arduous, and, of late years, onerous duties attaching to the position of honorary Secretary to the Society of Engineers. The untiring zeal and energy you have displayed during the whole of that period in the very successful management of its affairs, not less than the invariable courtesy with which the numerous duties of your office have been discharged, have caused the members and associates of this Society to unite in offering for your acceptance the accompanying silver service, as a token of their appreciation of your invaluable services. We, whose names are appended hereunto, on behalf of the members and associates of the Society of Engineers, therefore beg you will accept this Testimonial as an acknowledgment of your past exertions, to which the success of our Society is so largely due, and as a proof of the high personal esteem and regard in which you are held by all the members and associates of the Society you have so long and so well served. Our united and sincere wish is that you may continue for many, many years to retain the post of honour, which you now occupy, of honorary secretary to the Society of Engineers.

On behalf of the subscribers,

LEWIS OLRICK, Chairman	WILLIAM ADAMS, Treasurer
ROBERT BRASS	WM. MACGEORGE
JAMES HENDRY	P. F. NURSEY, Hon. Sec. to the Testimonial
BALDWIN LATHAM	JOHN PINCHBECK
W. H. LE FEUVRE	GEO. WALLER
WM. ROBERTS	
H. P. STEPHENSON	

Mr. ALFRED WILLIAMS, in acknowledging the presentation, stated that his thanks were first due to those who in the early stages of the Society were kind enough to place him in the position of honorary secretary. He would also thank those who from year to year had enabled him to maintain that position, in consequence of which he was now the recipient of that magnificent testimonial. There were several ways of showing to an individual the appreciation of his efforts to serve his fellow men, but he knew of no more effective way of testifying that appreciation than their meeting together on an occasion like the present. He hoped that the address which had been presented to him would hang for many years in some prominent position in his house to attest that at some period of his life his services had been deemed worthy of recognition. The name of the Society would always be associated with the testimonial, and would recal to his mind the many kindnesses he had received from the members and associates of this Society. He had obtained photo-

Digitized by Google

graphs of the service for presentation to the subscribers to the testimoual and to the company generally, as a memento to them of the kindness performed. The Chairman had stated that the success of the Society had been entirely due to him (Mr. Williams). If, however, he had not had such friends as were now around him, all his efforts would have availed but little. It had always been his opinion that such associations as these led to mutual friendships and business connections. During the twelve years he had been connected with the Society he had formed many valuable and lasting friendships. If gentlemen would join such societies as this, they would greatly add to their chances of success in life, and much mutual benefit would result from the union and interchange of ideas between the members. They should not keep their knowledge to themselves, because what was restricted was of no use to any one. The Chairman had referred to the publication of the transactions. The preparation of those transactions occupied, of course, a great deal of time, but that was compensated for by the fact that they had proved a great success, and were received by the scientific professions as volumes sufficiently valuable to add to their libraries. M. Flachat, President of the Society of Engineers of France, stated during the visit of our Society to Paris last year, that the very fact of the publication of its discussions so soon after they took place was acknowledged on the Continent to be one of the best features of any scientific society of this country. The past of this Society had been, as the Chairman had said, extremely successful. The present exhibited still greater success. As for the future, he hoped that during the next twelve years they might succeed in gathering together members in a greater proportion than during the last twelve years; that many mutual and valued friendships might be formed among the members and associates, and that the Society become and be acknowledged one of the first scientific societies in the kingdom. In conclusion, he would again offer his sincerest thanks to his friends for the very kind manner in which they had referred to his services, and for the very handsome and valuable testimonial they had presented to him.

Numerous other toasts of a complimentary character were given and acknowledged during the evening, the speeches being interspersed with songs. The arrangements of the presentation banquet were highly successful, and the company separated after a very pleasant evening, which left nothing to be desired—except, perhaps, that such another evening might occur soon—a desire, however, which is not likely to be gratified for some years to come in the Society of Engineers.

IMPROVED HYDRAULIC CRANE.

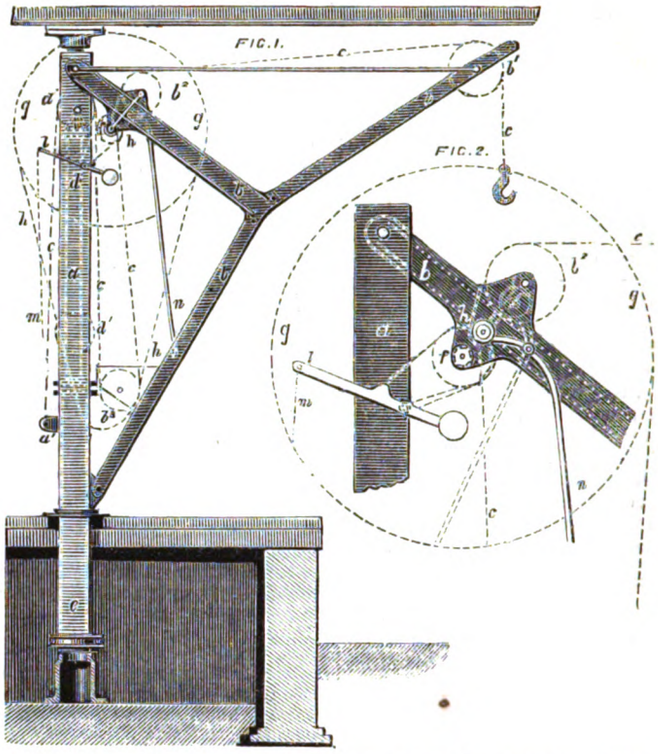
SOME improvements in cranes have recently been patented by Mr. Percy Westmacott, of Elswick, Newcastle-on-Tyne. His object is the combination of hand with steam, water, or air power by a ready means of attaching or disconnecting the auxiliary power to the lifting or hauling chain of the crane or hoisting machine. For this purpose he employs a drum which receives motion by means of the auxiliary power. The hoisting chain of the crane is arranged to pass alongside of the chain pinion, and when the auxiliary power is to be employed it is deflected from its direct course by a movable guide pulley mounted on a hand lever so as to cause the chain to bear against the chain pinion and to gear with it, the links of the chain being held by projections on the face of the pinion. When the auxiliary power is not required, by shifting the guide pulley the chain is allowed to pass clear of the pinion.

In our engraving, fig. 1 is side view of an hydraulic crane having Mr. Westmacott's auxiliary hand gear applied to it. a is the crane post; b the jib; c the lifting chain; it passes up over a pulley b^1 on the end of the jib, then around pulleys b^2 and b^3 and over a pulley d^1 mounted on the top of an hydraulic ram d working in a vertical cylinder e, and thence the chain passes to an eye a^1 on the crane post, where it is made fast. When it is desired to raise a weight attached to the crane chain, water under pressure is admitted to the cylinder e by valves, and the ram raises the pulley $d1$ from its lower position, in which it is shown in dotted lines, to its higher position, in which it is shown in full lines. Or the ram may be stopped by the valve when it has made only a portion of its stroke. The weight on the crane chain will be raised a distance equal to double the stroke of the ram. These latter arrangements, however, form in themselves no part of the invention; they are ordinary, and well known to our readers.

The auxiliary hand mechanism is shown on a larger scale at fig. 2. f is a pulley or drum of small diameter having recesses in its periphery to receive and hold firmly the links of the crane chain when it is caused to pass partly around it. This pulley or drum is mounted in bearings on the jib, and it has on its axis

HYDRAULIC CRANE.

BY MR. P. WESTMACOTT.



a large chain wheel g over which a hand chain h passes. k is a brake pulley on the axis of the chain pulley or drum f, and round it a brake strap passes to a lever l on the crane post. This lever is weighted, so that when the lever is left free the brake is taken off by the weight. m is a chain by which the brake lever is worked. The crane or lifting chain c, however, in passing direct from the pulley b^2 to the pulley b^3, does not come against the chain pulley or drum f, so that the main lifting mechanism can then be used altogether independently of the auxiliary hand mechanism. By means of the hand lever n, which is centered to the jib and has a small pulley at its upper end, the crane chain can be deflected, as our engraving shows it, from its direct course between the pulleys b^2 and b^3, and the crane chain then engages with the chain pulley or drum f, and then by using the hand chain and mechanism the crane can be used as a hand power crane whenever convenient to do so, or in cases of emergency produced by accidents to the hydraulic power.

AERONAUTICAL SOCIETY OF GREAT BRITAIN.

A GENERAL meeting of the members of this Society took place in the theatre of the Society of Arts on the evening of Thursday, March 26. The Duke of Argyll, President, took the chair at 8 p.m., when the proceedings commenced with the reading of a paper, by Mr. John Heath, on the control of balloons by pressure.

The plan proposed by the author was to encircle the sphere of the balloon by an exterior ring or belt of the same fabric stiffened by whalebone, and maintained at some distance from the sphere, so as to leave an annular passage. If during the ascent the lower loop of the belt is drawn eccentrically close to the balloon, and the upper one thrown out similarly in an opposite direction, it will set the whole belt in an inclined position, relative to the axis of the balloon, and, consequently, the current of air caused by the ascent rushing between the sides of the belt and balloon will cause the latter to rise in a path determined by the inclination of the belt. On descending, the belt is inclined the opposite way by means of suitable cords worked from the car, and the air again impinging on the belt, will still urge the balloon in the same direction, and by a series of these ascents and descents, the balloon will be caused to make progress in any required direction by means of a number of such traverses in a zig-zag course through the air like vertical tacking. The means by which the author proposes to obtain these alternate ascents and descents, without the expenditure of either gas or ballast, is by increasing or relieving the pressure of a stated weight at due intervals upon the bottom of the car by means of a system of cords and friction pulleys worked by a kind of windlass. The paper was illustrated by several elaborate and neatly-made models.

Mr. Wenham said,—The whole success of this plan must depend upon the force employed in obtaining an ascent or descent as required, but I must remark that I cannot see how any effect is to be obtained this way from an abutment contained within the machine itself. We have no power under such circumstances, that I am aware of, of destroying the force of gravity or creating it. Then, the elaborately-constructed car shown, and its contained machinery, is sure to be broken up on reaching the ground in even a seven mile breeze. As Mr. Glaisher can inform us, if the grapnel secures a hold, the balloon is sometimes ripped open by the wind from the base to the summit, and, on the contrary, if the grapnel fails in its hold, to make a rude but comprehensive comparison, the car is subject to a rough treatment similar to that of a tin kettle tied to a dog's tail.

The next paper read was by Mr. David Stephen Brown, "showing that for sustaining a body in the air by mechanical action, more depends upon the application of the power than on its actual amount."

It is not creditable to the present age that the principles employed in flying have not been elucidated. That it has not yet been practically demonstrated how an animal possessing a heavy body like a bird, is able to support itself with such ease in so attenuated a medium as the atmosphere. More especially is this felt when it is considered that the problem is of a mechanical kind, and that its solution involves the most perfect system of locomotion with which we are acquainted; for, not only is it found that a bird can fly faster than it can run, but, what is more, it can fly faster than the fleetest quadruped can run, notwithstanding that the quadruped is specially adapted for moving on the ground, and makes use of its four limbs for that purpose, whilst the bird is not specially adapted for moving in the air, and can, therefore, only use two of its limbs in doing so. Now, considering that muscular action is the common source of power in both cases, it follows that the difference in results must be ascribed to the merits of the respective media, unless it be assumed that birds make use of more muscular force in proportion to their weight than other animals. That they possess a greater amount of power is, I believe, quite true, but that they use it—or, rather, use it continuously in flying—is not possible, for the reasons which will be presently given. Indeed, I am inclined to think that the average amount of force consumed in flying is not

Digitized by Google

greater than in walking, and certainly not greater than in running, for it can be continued for a longer time than either.

Most people still believe that a bird is buoyed up in the atmosphere by air-cells, although the merest tyro in science should know that as the specific gravity of the entire body of a bird is several hundred times more than air, any support derived from such a source can only count as "the dust in the balance." Others, with more correct views, while fully comprehending that the support is due to motion, yet insist that the force required to accomplish it is so great as to preclude all hopes of being able to do so by machinery. This opinion may be correct when confined to the principle upon which the screw has as yet been employed as a sustainer where the action has been continuous, which is not necessary for merely obtaining support in the air, but causes an immense waste of power. In natural flying the force is employed intermittently, and great economy is the result. For example, the wing of a bird, although moving at the rate of sixty feet a second, when exerting its useful action, may only then pass over a space of 1ft., which it would do in the sixtieth part of a second, the remainder of the time being consumed in slower motion—in making return strokes, and in a state of rest. Again, it is well known that a body falls by the force of gravitation 16ft. in a second, and supposing it to weigh 1,000lb., this would represent a force equal to thirty horses, but by reason of the motion being an accelerating one, the same body would only fall 1ft. in the first quarter of the second, representing a power of less than eight horses, and in the sixteenth part of a second the fall would be $\frac{3}{4}$in., equal to two horses' power, whilst in the sixty-fourth part of a second the fall would be less than the twentieth part of an inch, or at the rate of 3in. in a second, which represents only half a horse power.

When, therefore, it is considered that the wings of insects vibrate more than a hundred times in a second, causing so many interruptions to the accelerating motion of gravitation, or minute elevations, how astonishingly small appears the power to sustain under such circumstances. Nor, after all, is it surprising, for in theory, at least, no power is required for support. It is for lifting, not sustaining, that force must be consumed. The velocity acquired by a body in falling from any height is sufficient to carry it back to the same elevation from whence it fell, as seen in the pendulum of a clock, and still more to the purpose in the flight of a bird when making a swoop.

I have not deemed it necessary to touch on the subject of propelling in the air, because it is precisely analogous to screw propulsion in the water, which is too well understood to need any discussion; and the same applies to steerage, which is dependent on it. But, as regards the supposed great difficulty connected with artificial flying, namely, the power required for sustaining, I have endeavoured to show that this depends more on the application than on the actual amount, and should this view of the matter (corroborated as it is by the valuable contributions of Messrs. Wenham, Smyth, and Artingstall), be deemed correct, the prospect before us will be indeed cheering, for it cannot but be believed that with the immense engineering resources now at our command means will be found to apply force in any manner that may be required, and thus by machinery we may soon achieve the same locomotive triumphs in the air as have already been obtained on land and on water.

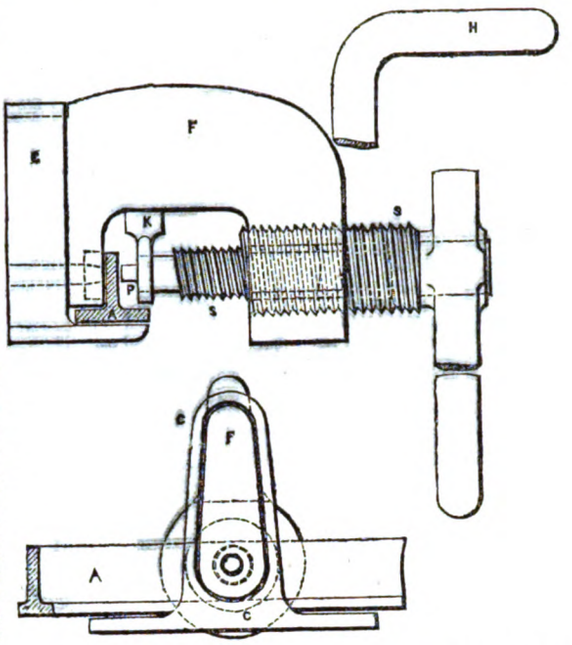
DISCUSSION.

The Duke of Argyll said,—I entirely agree with the principle just laid down, that there is much more to be done in studying the application of power than in increasing the quantity; but I think Mr. Brown is rather too sanguine as to the possibility of obtaining a sufficiently light motive power in the present state of science. The steam engine at the present day represents the greatest force to be obtained as yet. It is, however, not only a very heavy cumbrous metallic body in itself, but it requires a large supply of water and fuel to enable it to do its work; these are additional heavy bodies, and the combined weight of the machine altogether precludes the hope that an engine can be so made as to raise or move itself in the air. Still, the absence of the lighter motive power required ought not to stop us from investigating the principle upon which it is to be applied. Science one day will, no doubt, attain to this desired motive power, and I think that Mr. Wenham's paper, in addition to this one just read, goes far to show the principle upon which the power may be applied.

(To be continued.)

PORTABLE PUNCHING MACHINE, METROPOLITAN RAILWAY.

THE accompanying sketch illustrates a light portable machine for punching small holes through wrought-iron plates or bars in situations where the ordinary form of punching machine would be inapplicable. In glazing the roofs of the Metropolitan District Railway stations, it is found necessary to insert pins or dowels at intervals through the T-iron sash bars carrying the glass, this involves the punching *in situ* of a large number of holes, varying in size from 3-16in. to 5-16in. diameter. The following is a description of the machine designed by Mr. Edward W. Furrell, and adapted for this purpose:—A is the T-iron sash bar carrying the glass, a small hole being required near the middle of its centre rib, as shown: F is the frame or holder carrying a differential screw; S S' working through the solid metal of F (the outer screw S' is of greater pitch than the inner screw S), and having the punch P at the extremity of the inner screw S; H is a handle acting upon the outer screw S'. By the action of the differential screw a few turns of this handle gives the required motion to the punch P and forces it through the T-iron sash bar; by reversing the motion of the handle the punch is withdrawn. C is a wrought-iron ring slipped on to the end of the holder F, and terminating in a foot or clip, which passes underneath the sash bar and effectually holds the machine in position whilst operating upon the handle H; K is a guide ring for preventing the inner screw S from turning during the action of the screw S S'. The mechanical advantage of this screw is the circumference described by the power divided by the difference between the pitches of the screws S and S'.



The dimensions of the machine in operation are as follows:—Outer screw S', $1\frac{3}{4}$in. diameter and 1-6in. pitch; inner screw S, 1in. diameter and 1-8in. pitch; diameter of punch from 3-16in. to 5-16in.; circumference described by power, 100in.; weight of machine complete, 20lb.; size of T-iron sash bar $1\frac{1}{2}$in. by $1\frac{1}{4}$in. by $\frac{1}{4}$in.; average rate of punching with this machine, thirty holes per hour.

MIDLAND BOILER ASSURANCE COMPANY.

MR. E. B. MARTEN, chief engineer to the Midland Steam Boiler Inspection and Assurance Company, has issued his report on boiler explosions in 1867, which forms an appendix to the twelfth half-yearly report of the company. There can be no doubt that periodical inspection is the best safeguard against the explosion of steam boilers, and Mr. Marten's report shows that nearly all the explosions last year resulted from simple and well understood causes, and could have been prevented by proper examination. Mr. Marten's report is accompanied by some useful sketches to a uniform scale, showing the relative size and shape of the boilers, and also the effect of the explosion, by the fragments being arranged as near as possible to their original position. None of the exploded boilers were under the care of this company. Records are given of forty-eight explosions, causing the death of seventy persons, and the injury of eighty-eight others.

The exploded boilers were of the following descriptions:—

	Explosions.	Killed.	Injured.
Domestic	6	5	4
Cornish or others, with internal flues	17	29	30
Plain cylinders, without internal flues	13	19	32
Multitubular	6	12	14
Balloons	2	2	2
Various	4	3	6
	48	70	88

The exploded boilers were used for the following purposes:—

	Explosions.	Killed.	Injured.
Domestic	6	5	4
Collieries	7	12	16
Railways	5	2	7
Ironworks	3	2	6
Farms	3	11	10
Paper, spinning, dye, wool, flour, wire, and other mills	20	37	45
Unknown	4	1	0
	48	70	88

The causes of explosion may be thus stated:—

	Explosions.	Killed.	Injured.
Frost in the pipes of domestic boilers, without safety valves	6	5	4
Old and worn out; plates injured by too frequent or neglected repair, or accumulations over the fire	7	14	20
Faulty construction, or bad material or workmsnship, tubes without strengthening rings, flat ends insufficiently stayed, no provision for expansion, insufficient strength of manholes	15	17	26
Undue pressure from safety valves being fastened, or overloaded, or otherwise rendered inefficient	5	13	12
Corrosion at parts touching brickwork, and which might easily have been detected by inspection	8	14	13
Overheating through shortness of water	2	1	4
Carelessness in arrangement or management of fittings	2	3	2
Unknown, no trustworthy particulars having been obtained	3	3	7
	48	70	88

A glance at Mr. Marten's graphic illustrations, showing something of the wreck and damage of the past year, and the fact that none of the exploded boilers were under the care of the company, ought to suffice to make every steam user place himself under the protection of assurance and inspection.

THE following gentlemen will act as presidents of the various sections at the Norwich meeting of the British Association for the Advancement of Science:—Professor Tyndall, mathematical section; Mr. Frankland, chemical section; the Rev. M. J. Berkeley, biological section; Lord Strangford, geological section; Right Hon. W. E. Gladstone, M.P., statistical section; and Mr. G. P. Bidder, mechanical section. Professors Olley and Huxley, together with Mr. Scott, of the Board of Trade, are also expected to deliver lectures.

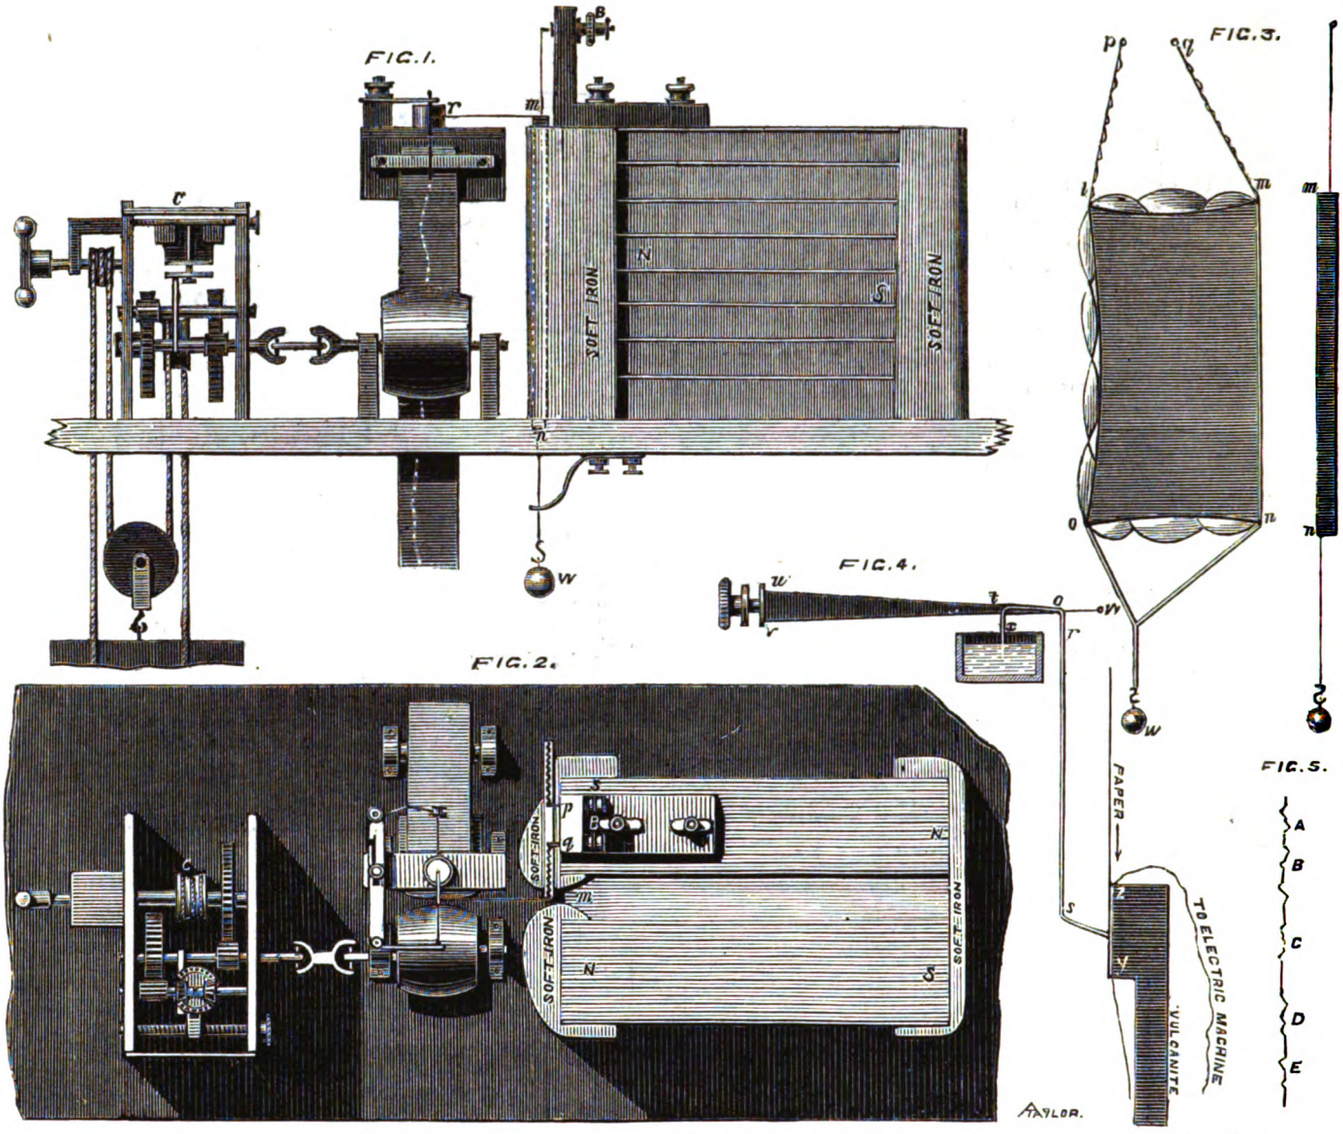
RECORDING TELEGRAPH INSTRUMENT.

BY SIR WILLIAM THOMSON.



SIR WILLIAM THOMSON'S NEW READING TELEGRAPH INSTRUMENT.

THIS new apparatus is designed by its distinguished inventor to record permanently such signals as have hitherto been received upon the Atlantic cable by his beautiful mirror galvanometer. The peculiar merit of the mirror galvanometer lies in the fact that it has a shifting zero, that it continuously indicates the variations of strength in the received current, even of the most delicate kind, and it enables signals to be received and interpreted which would be invisible on other apparatus. The new instrument replaces the movement of the spot of light by a curved or broken line, drawn or marked upon a strip of paper which gives a graphic representation of the varying strength of the current, and a permanent record of every feature of the effect due to the sender's action.

The difficulty hitherto experienced in producing such a recorder has been that of obtaining marks from a very light body in rapid motion without impeding that motion. Marks, either by points, pens, pencils, &c., introduce friction, and electrolytic action requires power exceeding the limits of safety. Sir W. Thomson has overcome the difficulty in an exceedingly beautiful and novel manner. The mirror of his galvanometer is replaced by a light capillary glass tube attached to a very light stiff coil of a small number of turns of fine wire, moving in a very powerful artificial magnetic field. He thus reverses the conventional system: the magnet is fixed and the coil movable. As the relative motions of magnets and currents are simply due to the reciprocal action of each, and are measured by the ratio of the strength of the magnetic field to the strength of the current, it is evident that by increasing the intensity of our magnetic field, which we can do *ad libitum*, we can produce motions upon the very lightest currents. Sir W. Thomson only uses a coil of a resistance equal to 20 Ohms, and he has obtained good results with copper wire weighing about $\frac{1}{4}$ grain per foot, and with coils containing about 20 turns. The strength of his signals with the same power are greater with the new instrument than with the mirror galvanometer; and the delicacy of his new recorder is such that a single Daniell's cell produces perfectly distinct signals through 8,000 Ohms, a resistance exceeding that of the Atlantic cable. One end, the short leg, of the light tube, which is a syphon, dips into an ink reservoir, and its long leg points obliquely downwards, its end being opposed, without touching, to a strip of paper which moves vertically in front of it. The paper is drawn over a metal plate which is electrified *positively*; the ink reservoir is electrified *negatively*. We have thus two points oppositely charged which tend to cause a succession of sparks to pass between them, but which under the circumstances produce a fine stream of ink, spirted out by electric force, and drawing or marking a sensibly continuous line without impeding by friction the motion of the tube as directed by the receiving instrument. Earth currents would cause the syphon to make long sweeps from side to side on the paper, still leaving the alphabetical curve clear and distinct.

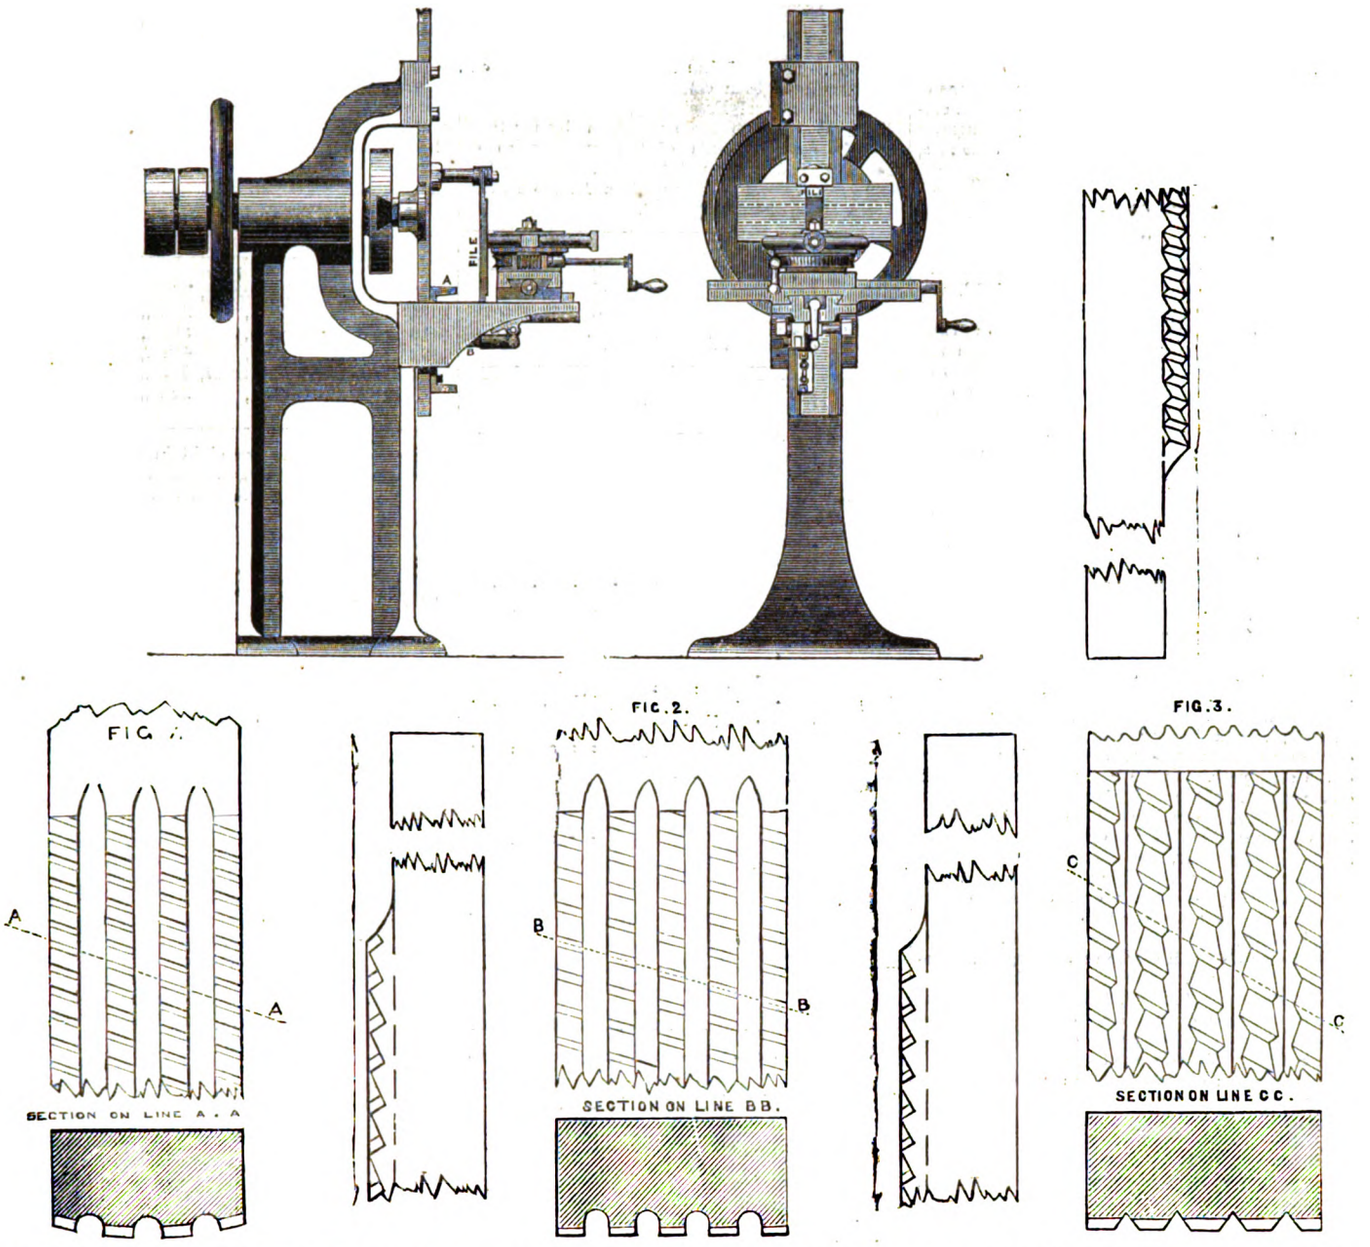
In the accompanying illustration, fig. 1 is an elevation, and fig. 2 a plan showing the principal parts of the recording instrument. A large permanent compound steel magnet, N. S., made of a large number of straight steel bars with a soft iron junction piece, and soft iron poles, is used to produce a very intense magnetic field in the deep narrow space separating the poles, shown in plan at m, fig. 2. The light coil of fine silk-covered copper wire is shown in fig. 3, the wire is stretched on a couple of light struts or booms between $l\ m$ and $o\ n$. The side $m\ n$, composed solely of the fine wire, is formed into a thin flat cake by being cemented with paraffin. The side $l\ o$ is strengthened by a strong thread to relieve the copper wire from strain, and the axis of suspension is placed nearer the strengthened side. The coil is suspended by two fine silk fibres $l\ p$ and $m\ q$, so that the side $m\ n$ hangs in the magnetic field between the poles of the magnet, and is free to oscillate in a direction parallel to the straight bars forming the magnets; the two ends of the wire are twisted round the suspending fibres, and are attached to the terminals B B. The weight w keeps the coil in shape, and adds directing force to the coil. The peculiar form of the coil allows it to approach very close to the magnetic field, and the depth of the side $m\ n$ exposes a considerable length of wire to magnetic action. The capillary tube or syphon is shown in detail in fig. 4, marked $t\ r\ s$ and is attached to the top of the side $m\ n$ of the coil by a single silk fibre $m\ r$, the syphon being suspended with double threads $t\ u\ x\ v$ at one side, and a single thread $v\ w$ at the other side, so as to oscillate round a horizontal axis. The directing force of the double threads is adjusted so that the syphon can follow the movements of the side $m\ n$, to which it is attached, keeping the single fibre $r\ m$ always taut. The distance of the point of attachment r from the axis $t\ w$, is about 1-10th the length of the long leg of the syphon, so that any motion of the side $m\ n$ may be represented by a tenfold motion at the end of the syphon.

In fig. 4 the paper is shown on which signals

Digitized by Google

FILING MACHINE AT THE STAMP-END WORKS.

DESIGNED BY MR. G. WILKINSON.



are recorded, moving vertically past the long end of the syphon, the short end of which dips into a dish of ink. A brass plate, *x y*, across which the paper is drawn in front of the end of the syphon is connected with an electrical machine, and is kept constantly charged with electricity, whilst the syphon is in connection with the earth. When the recording instrument is at work, the brass plate and paper crossing it being highly charged with electricity, attract the end of the syphon, and under the influence of this attraction, and of a rapid vibration produced in the end of the syphon, and which is due to continual small electrical discharges, the ink flies in a succession of fine drops from the syphon to the paper. These drops blend into a continuous line on the paper as it is drawn regularly forward. This line records the position of the end of the syphon at each moment as it is moved backwards and forwards across the paper by the silk fibre *r m*, attached to the side *m n* of the receiving coil. The line drawn on this paper is, therefore, a continuous curve corresponding to the motions of the side *m n* of the receiving coil, and, therefore, to the varying currents producing the motions, and to the signals which those currents indicate. When no current is received a simple straight line will be drawn along the paper; short positive and negative signals will draw small ripples on either side of the zero line; in fig. 5 may be seen the curves representing the letters *a*, *b*, *c*, of the Steinbiel code. This beautiful instrument is intended to receive and record all signals such as have hitherto been received on the mirror galvanometer, thus doing away with the inconvenience of a darkened room, and avoiding the necessity and consequent risk of additional error of an extra repetition of signals. The invention is patented.

FILING MACHINE AT THE STAMP-END WORKS.

WE believe we are right in stating that within the last eleven years Messrs. Clayton and Shuttleworth, of Lincoln, have turned out a greater number of small steam engines—portable and stationary horizontal engines, for farm purposes—than any other makers. They have, accordingly, been enabled to carry out very extensively the use of special tools for finishing a large number of duplicate details. The connecting rods, for instance, are only just touched by the file in order to take off the slight burr, or arras, left on the edges of the straps and brasses on coming from the slotting and shaping machines. The fine last cut taken quite obviates even the use of the draw-file. The cottar holes are, of course, done in a slot-drill, and the semi-cylindrical edges of the cottars themselves are shaped in a special semi-rotating lathe by Smith, Beacock, and Tannett, of Leeds. The brass eccentric straps employed for the engines made at the Stamp-End Works are flat on the outside, and this part of the strap could thus with fair economy be finished in a slotting or shaping machine. But Mr. George Wilkinson, Messrs. Clayton and Shuttleworth's engine-shop manager, has found it yet more economical to employ the ingenious and original machine we now illustrate. The two halves of the eccentric straps are cast in one piece, and of course first turned up, and after the outsides have been got up they are slotted in two, the small space made by the slotting tool being afterwards filled up by a packing piece for taking up the wear.

The tool is like a small slotting machine, with the usual crank and slide for giving a reciprocating motion to the slotting frame. Instead of an ordinary cutter, however, the frame holds a sort of rough file, or even an ordinary file. The three different kinds, portions of which we have illustrated full size in figs. 1, 2, 3, are employed for roughing over the brass clips, which are afterwards finished with a file cut in the ordinary way. The slide table on which the pair of clips, still in one piece, are held by means of a bolt and a round plate, is fitted with a compound cross-slide and circular motion. The work is thus easily set and traversed under the tool; it can be rotated by the worm and wheel, and a very complex shape can be brought up to the toothed cutter or file. Provision has of course to be made to take the work beyond the range of the file on the return stroke of the machine, just as a hand-file has to be slightly lifted off the work on being drawn backwards. The sliding tool frame is hence furnished with two

Digitized by Google

stop pieces, A A, which come in contact at each end of the stroke with a tappet lever fixed on a nut on the screw B. The other end of this screw is jointed to a rocking shaft carried at each end by two small brackets. This shaft itself, by means of a lever in the middle, acts on the slide table. The top stop then slightly moves back the table, just sufficient to clear the tool on the upward stroke of the file; and the bottom stop brings the table forward in time to receive the downward cut of the tool. The engravings of the full-size portions of the roughing-out tools show the kind of teeth employed. The entire length is 1ft. 2in., the narrow one 1in., and the two others $1\frac{1}{4}$in. wide on the face, with a depth, at the toothed part, of $\frac{3}{8}$in.

SOCIETY OF ENGINEERS.

(Continued from page 241).

UNDER date the 30th of January, 1850, the Court of Directors of the East India Company ordered the appointment of commissions in each presidency to inquire into and report upon the system of public works, and the whole subject of their superintendence and execution. The consequence of the reports of these several commissions was the establishment of regular public works departments for each presidency, in whom was vested the control of all kinds of public works. At first the engineer branch of the department consisted principally of military men, many of whom were officers of the Engineer Corps and Artillery, but some were drawn from the line regiments, of whom it is no exaggeration to say that many were not possessed of the slightest qualification for such appointments. In the early part of the year 1855, twelve engineers and twelve overseers were, at the request of the Government of India, sent out from this country for special employment on the irrigation works then in progress in the North-Western Provinces and the Punjab; and a further number of twenty-five engineers and overseers were sent out in the course of the same year. In the early part of 1859 six civil engineers of the rank of executive engineers, fourth class, and special assistant engineers, were sent out for service under the Bengal Government, and in the same year, in consequence of the necessity for annually recruiting the Public Works Department by engineers sent out from this country, it was determined to hold competitive examinations, to which any young men who had qualified, by a certain course of professional training, were admitted. The first advertisement was issued on the 4th of March, 1859, and the examination commenced on the 10th of May following. Forty-eight appointments were offered to competition, but only thirty-seven of the candidates were found qualified; of these fourteen were appointed to the Engineer Branch, and twenty-three to the Upper Subordinate Branch of the Department. All of the latter grade were, soon after their arrival in India, promoted to the Engineer Establishment, as they evidently belonged to a better class than that of which the Upper Subordinate Establishment was generally constituted. No more appointments of the lower grade have since been made from this country (with the exception of four who were sent out in 1860), but annual examinations have been held at the India Office, since 1859, for appointments to the Engineer Establishments. In consequence of the pressing want of more engineers—principally in connection with the proposed extension of irrigation works throughout India, which are henceforth, to a great extent, to be carried on by means of capital borrowed for the purpose, and which will be employed to augment the usual annual grants from surplus revenue—a second examination was held in December last, at which twenty-five appointments were offered for competition; and in the early part of the present year thirty temporary appointments to some of the higher grades in the department were made in this country in order to meet the immediate and pressing want of engineers in India. Altogether, since 1859, 181 engineers have thus been appointed from this country to the Engineering Establishment of the Public Works Department in India. The demands of the service for more men are still urgent, and in all probability will continue so for many years to come, as the increase in the prosperity of the country demands the construction of more public works for its necessities and conveniencies. Hitherto it has been found difficult to maintain the established proportions of military and civil members laid down for the Department. This is a difficulty which is likely to increase rather than to diminish, and it may with some reason be expected that India will for many years to come provide the best field for the energies of our profession.

In order to give some general idea of the prospects of the Government service in India, it may be as well to state the salaries of the several grades in the Public Works Department, and the average length of service, before reaching each grade. These particulars have been compiled from official documents, and can be vouched for as substantially correct. It is true that they have been calculated from the returns only of the Bengal Presidency, but as that establishment contains more members by far than both the establishments of the presidencies of Madras and Bombay put together, it affords the best general average of promotion for the Public Works Department in general.

Assistant Engineers, 1st grade.	48 civil	7	4
		6	2

It must be stated, however, that these figures do not correctly show the average length of service which civil engineers going out from this country must expect to pass before getting promotion from one grade to another, as in each grade there are one or more who, from their exceptionally long service, cause the general average to be unduly raised. Thus, amongst the assistant engineers of the first grade there is one who has served 19 years 7 months, another 17 years 7 months, another 14 years 9 months, and another 11 years 11 months. Amongst the executive engineers' fourth grade, are those who have been in the service for 19 years 1 month, 16 years 11 months, 16 years 10 months, and so on.

With only two exceptions, none of the civil engineers who have been sent out from this country since the year 1855 have yet attained a higher rank than that of executive engineers' first grade. The following statement gives the number of civil engineers appointed from this country, in each grade, and the average length of their service before being promoted to that grade:—

No.	Rank.	Average Service.	
		Yrs.	Mon.
5	Executive Engineers, 1st grade	8	11
1	" " 2nd "	9	5
10	" " 3rd "	8	8
22	" " 4th "	5	9
21	Assistant Engineers, 1st "	3	8
8	" " 2nd "	1	3

Besides which there are eight in the third grade of assistant engineers, amongst whom, however, there is only one included who went out during last year. Omitting, then, the seventy who have been sent out from this country within the past twelve months, for employment in the Public Works Department, the foregoing particulars relate to all but thirty-five of the total number sent out since 1859, a few of whom belong to the Public works Departments in the other presidencies, some have left the service, and others have died.

Finally, it may be stated that the author of this paper has seen the several attacks made on the Indian Public Works Department, which have appeared from time to time in letters to the "Builder," the "Engineer," and the "Irish Times"; but, with the single exception that the salaries on first appointment are not sufficiently high to attract young men of promise from this country, there has not been one complaint thus publicly made which cannot be most positively contradicted. Several instances have also come to the knowledge of the author of this paper of persons having left the department with the supposition that they could obtain better appointments, seriously regretting that action as a false step, and desiring to be re-admitted to the service. Some have succeeded in re-establishing themselves upon the strength of their own merits, others have failed. If the remuneration of Government service is comparatively small, it must be remembered that it is sure, and that the reversion of a pension after a certain number of years, though perhaps remote in its realization, is yet equivalent to an increase of income. The public service is an honourable service, and, though the prizes may appear few and remote to beginners, it may be stated in full confidence that they are certain of attainment, in due course, by the honest and persevering.

THE THAMES EMBANKMENT.

MR. BAZALGETTE, the Chief Engineer to the Metropolitan Board of Works, has presented a report to the Board having reference to the arrangements for opening the Thames Embankment, road, or footway, during the ensuing summer. Mr. Bazalgette says, that to form the carriage-way along the face of the embankment would not at present be prudent, because it would have to be taken up for the construction of the Metropolitan District Railway underneath it. The specification and drawings now submitted for the approval of the Board provide for the formation of a paved footway, 20ft. wide, along the face of the embankment from Westminster-bridge to the west end of the Temple-gardens. Two approaches will be connected with Westminster-bridge, one down the steps to and along the new steamboat pier, and the other at the back of the pier, by a gradual incline from the level of the bridge down to that of the embankment. A subway for foot passengers is to be formed from the Houses of Parliament underneath Bridge-street to the station of the Metropolitan District Railway, and Mr. Bazalgette is now in communication with Mr. Barry with a view to submitting for the consideration of the Board a design for the continuation of that subway to give access to the Westminster steamboat pier, and for allowing foot passengers to pass from the footpaths on the Thames Embankment to any part of Westminster without encoun-

Digitized by Google

tering the carriage traffic in that locality. A temporary paved foot approach is proposed to be formed from Villiers-street, Strand, to the embankment roadway and Charing-cross steamboat pier. Some arrangement will have to be made with the South-Eastern Railway Company in order to maintain the full width of this approach at the upper end, and it would be to the public advantage and the company's interest that they should also form an approach by steps from the footway at the side of the Charing-cross railway bridge down to the embankment footway. A third temporary paved foot approach would be formed from the steps at the side of Waterloo-bridge, giving access between Wellington-street and the Waterloo steamboat pier. The fourth temporary paved foot approach would be from the steps at the end of Essex-street, Strand, to the Temple steamboat pier, which, for the present, would be the eastern end of the Thames Embankment promenade. A communication may also be made with the Temple-gardens, if desired by the representatives of that property. The whole of these footways will be fenced off by temporary wooden fencing, and may be opened to the public in the course of the coming summer.

IRON-CLAD SHIPS.

ON the evening of Friday last, Mr. E. J. Reed, the Chief Constructor of the Navy, delivered a highly instructive and interesting lecture on iron-clad ships, at the Sailors' Home, in Dock-street, near the London Docks. The large dining hall which accommodates about 500 persons, was on this occasion converted into a lecture hall, and some 300 tenants of the "Home" and visitors attended. The walls were covered with diagrams, and the lecture table with models of iron-clads and of armour-plates. Mr. Reed commenced by describing the floating batteries which were used against the Russian forts during the Crimean war, and then explained the various steps which had since been taken by the Admiralty for increasing the naval defences of this country. He minutely described the peculiarities of each successive step, which had been devised and launched under his own direction, and entered especially into the question of their vulnerability or otherwise. Comparisons were also instituted between French and English vessels of war, which resulted in a demonstration of the superiority of the latter over the former. The various kinds of backing, and of inner skins employed in the construction of iron-clad ships, and of experimental targets for testing the penetrative powers of the Whitworth and other guns, were explained, and then the lecturer advanced to a consideration of the fleet of the future. Although carefully guarding himself from divulging the plans of the Government, it was quite apparant that Mr. Reed's inclination was towards the introduction of shorter ships, thicker armour-plates, increased steam power, twin-screws, and greater coal stowage. The lecture, which lasted an hour and a-half, gained the close attention of a very appreciative audience, in which the nautical element strongly predominated. Captains Fremantle and Pollumbe, R.N., respectively proposed and seconded a vote of thanks which, with the addendum of three hearty cheers given by the sailors present, was finally awarded to the Chief Constructor. The Rev. Dan Greatorex, the indefatigable chaplain of the "Home," and who was himself originally an engineer, presided, and he was supported by Major Joselyn, Captain Kintoul, Mr. Newton, of the Mint, Mr. Graveley, and other scientific gentlemen. Altogether, the proceedings were of a gratifying nature, and certainly a more appropriate locality could scarcely have been chosen for such a lecture.

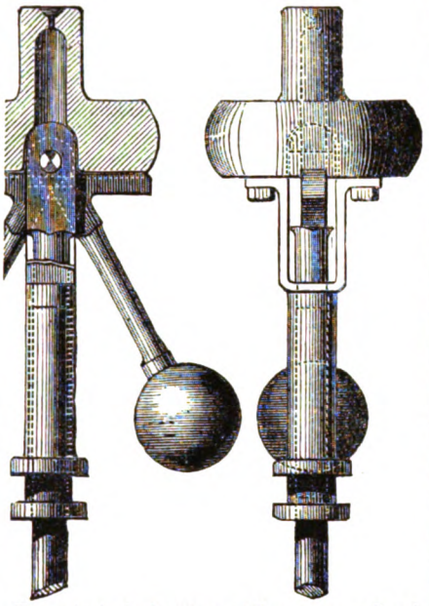
BELGIAN TELEGRAPHS.

THE telegraphic systems of Belgium, which are managed by the State, have now been established sixteen years, and the cost of their establishment have been entirely covered by the surplus receipts. The annual cost of the service is about 840,000fr.; but this sum does not strictly represent all the cost of administration, inasmuch as many buildings occupied and much assistance rendered by the railway and Post-office employés should be included in the general estimate. But, on the other hand, the telegraph gives to the other departments more than it borrows from them, for, according to returns for the year 1866, it appears that out of nearly 312,000 official messages transmitted during the year, 28,000 only were on account of the telegraph service itself. There are 106 telegraphic offices in operation in the stations of the State railways, fifty of which are used almost exclusively by the various departments of the Government, and very seldom indeed by the public. The night service, also, which is managed by a staff of fifteen clerks, is seldom required for other than messages in connection with passengers and goods' trains, so that, in fact, it is difficult to estimate the total cost of the service, inasmuch as it receives and gives in return benefits that could not be obtained on equally advantageous terms elsewhere. During the years 1864, 1865, and 1866, the inland messages cost more than they produced, and it was found that all the profit which had accrued arose from international messages—for inland messages require two sets of operations, international messages one set of operations only, and a message in transit merely requires re-transmission, without any cost for receipt or delivery. The tariff for an inland message is now reduced to half a franc, which involves a present sacrifice that could not have been borne unless the result of the first ten years had been superlatively prosperous. The real net profit of the year 1866 amounted to more than 122,000fr., and it is anticipated by the administrators that a reduction will shortly take place in the cost of working and on the average loss on each inland message, and that an increase of profit will obtain on each international or transit message.

IMPROVED GOVERNOR.

IN our report of the machinery at the Cattle Show last Christmas, we noticed a neat arrangement of centrifugal governor applied by Mr. Kinsey, of the Robin Hood Works, Nottingham, to his horizontal engines. From our illustration it will be seen that a cheese-shaped disc is placed at the top of the spindle, which is raised by the divergence of the balls, which are very small and driven at a high speed, securing very sensitive action.

FIG. 1. FIG. 2.



The principal advantage of the governor lies in its extreme simplicity; only a single pin is used, and therefore the surfaces exposed to wear are reduced to a minimum. The means by which motion is communicated to the throttle valve will be easily comprehended from the engraving. A number of these governors are now working very satisfactorily.

IRON FORTS AND HEAVY GUNS.

IT is with very considerable interest that we have observed so many notices entered by members of the House of Commons in respect to our national defences upon the production of the army estimates. Without doubt the defences of the country are not in a satisfactory state. We have never been alarmists, but we have been to the front in urging a judicious and proper expenditure of the vast sums of money which have been demanded and obtained for our new forts and fortifications. No less than £12,000,000 was their first estimated cost, and the subsequent introduction of iron shields and casemates will increase that amount by hundreds of thousands of pounds. And yet, notwithstanding the enormous sums so required, no trial of models of the works in progress have yet been made. Of the shields of the notorious Gibraltar class, which were made anp shipped to their destination before a single one was shot at, two are now to be brought home again, if we are correctly informed, for experimental trials to improve their structure. These unfortunate affairs wo would be willing enough to write off from memory, like bad debts, as a simple loss; but the same fatal error is being repeated over again in respect to the Bermuda and Plymouth forts. The representative section promised so long ago, when the contracts were first taken, to be shot against at Shoeburyness, is still tardily erecting, and will not in all likelihood be properly fit for half a year to come, and certainly even the iron portion could not be got ready, in any sense of that word, under six or eight weeks. But during all this time the contractors have been proceeding with their works, and in all likelihood the forts will be delivered to the nation before the model of the system on which they are built is ready for testing. And this model, when tested, will fail—will fail notwithstanding the many strengthenings and material modifications it has undergone at the hands of the Royal Engineers since the contracts it was intended to represent were taken. It was costly enough experimenting with Armstrong guns, and vexatious enough to have a result of nearly nil for many years' labour and millions of money, yet there was a justification for trying to make breech-loading cannon, and there would be still again if any likely plan were offered. But it would be dearer far and more calamitous to build iron forts which will not keep out the shots from naval guns. The iron plank system upon which the forts now erecting are designed, is, we have always contended, a defective one. And yet the work is going on untested, although the Minister for War himself has so far acknowledged the justice of the objections raised as to order a model for trial. If, as before, the works are finished before the models are tested we shall ten years hence be in the same plight with our fortifications that we are now with our guns. Why the haste to complete contracts for forts when there are no guns to arm them with is beyond all comprehension. Our newest ships, the "Hercules" and "Northumberland," will have to borrow from the land service, if the land service have any to lend them, some portion, at least, of their heavy guns, and the manufacture of large artillery is therefore as essential and of more immediate importance even than forts. And yet forts are important, too, for Russia is now having made in this country a shield of 18in. thick, composed of two large interlocking plates without bolts, and if this prove successful an order for 200 others will be forthwith given. Turrets, too, for ships, of 21in., in two plates, are about, we hear, to be produced for foreign governments.

As to heavy guns, the Americans, it is known, possess more than a hundred 20-inch 50-ton smooth-bore guns, throwing with 200lb. charges 1,080-pounder shot over a range of 4½ miles. Supposing the shells which these guns could hurl to a much greater distance to be 4in. thick in wall, the spherical bursting charge taken at 850 cubic inches would be 30lb. of powder, the destructive effect of which would be considerable. The Americans have monitors now carrying 16in. of laminated plating; and a powerful rolling mill without fly wheel, has, we believe, been ordered from one of our eminent midland manufacturers, so that thicker plates may be expected hereafter to form their mail.

Now, there is an essential condition of heavy projectiles which has not yet received proper attention in any discussion upon these topics in this country. It is the much greater distance of range over which the larger shot retain their energy than do the smaller ones. The resistance to the flight of projectiles is as the squares of their surfaces to their velocities. But the energy or momentum is as the cubes of their weights. Our 9-inch rifled gun with 250-pounder bolt would pierce at 200 yards an American monitor's 16in. of plating. The American ordinary heavy 450-pounder guns would pierce the "Hercules" at 200 yards. The vessels therefore could hardly fight at close quarters, or if they did both armaments would be equally effective, and both vessels alike vulnerable. All might have been said against the larger American guns that could be urged against smooth-bore cast iron cannon and spherical shot; but Ericcson is making a large wrought iron 20-inch gun, and we may therefore argue in our more familiar way of increased calibres of rifled guns. The 250-pounder projectile from our 9-inch gun, at a velocity of 1,340ft., would penetrate a 9¾-inch armour plate; our 400-pounder from the 10-inch gun would, with a velocity of 1,290ft. penetrate an 11-inch plate; our 600-pounder at a velocity of 1,220ft. would penetrate an 11½-inch plate; while the 1,200-pounder shot from a 15-inch rifled gun would at a velocity of 1,340ft., penetrate a solid 16-inch armour plate. It is true we have not yet made a 15-inch rifled gun, but the Royal gun factories are happily alive to the emergency, and desire to stake their reputation on the production of a 60-ton gun. We may, however, theoretically put the value of such a weapon before our countrymen in a somewhat more ordinarily comprehensible way. Its shot would, fired with 200lb. of powder against the "Hercules," pierce her thickest water-line plating at 2,000 yards. To give the power of this shot, as accurately as can be estimated, it would at that distance have a velocity of 1,156ft., and be equal to penetrating a 13¾-inch solid plate.

In conclusion, it will be well to state what guns we have fit for service. The seare:—Of 6½-ton

Digitized by Google

7-inch rifled guns (115-pounders), on Royal gun factory system, 332, and on Fraser system, 180; of 7-ton 7-inch rifled guns (115-pounders) 51 on R. G. F. system, 12 Fraser system; of 8-inch 9-ton rifled guns (180-pounders), 77 on R. G. F. system, and 2 on Fraser system; of 9-inch 12½-ton rifled guns (250-pounders), 188 on R. G. F. system, and 70 on Fraser's system. There are also 51 smooth-bore 9-inch wrought-iron muzzle-loading guns (100-pounders), on R. G. F. system. The respective charges of the above guns are—7-inch gun, 22lb. l. g. r. powder; 8-inch, 30lb.; 9-inch rifled gun, 43lb.; and 9-inch smooth-bore, 25lb.

Of guns larger than the foregoing there is one 18-ton 10-inch rifled muzzle-loader, on Fraser system, at Shoeburyness; the "Horsfall" or Mersey smooth-bore 13-inch gun (500?-pounder); and five 12-inch rifled 600-pounders in the workshops at Woolwich; two on Armstrong system, finished; and three on Fraser system, finishing. The present capabilities of the Royal gun factories are equal to producing twenty heavy guns in six months; a single one could not be produced in less time. It is well, therefore, that these facts and considerations should be duly weighed in the coming discussions which are inevitable both inside and outside the House of Commons.—"Standard."

ORIGIN OF COLOUR AND THEORY OF LIGHT.*

By Mr. J. Smith, M.A.

ON a former occasion the author proved experimentally that colour could be produced by the mere motion of a white ray without the aid of refraction; his object now was to explain those physical laws by which colour is produced from a homogeneous substance. He argued that as we hear through the medium of the air—a homogeneous substance—and the variety of sounds is equal to the variety of colours, we may have as great a variety of colour from the ether considered as homogeneous as of sounds from the air so considered. The difficulty was to prove by what process nature modifies so wonderfully the motion of a homogeneous substance. Many years ago he found that by pressing a piece of glass with a point he obtained colours. If the glass pressed were laid on an irregular surface, as a piece of ivory or steel, the colours were in irregular patches; but if the glass were laid on another piece of glass, the circles were complete. This proved that Newton's rings, as they are called, were produced by undulations or waves in the glass, that these waves are virtually small prisms, and that they are stationary as long as the pressure is stationary.

He afterwards found that similar waves or bands exhibited themselves in a film of soap when made to cover the mouth of a tumbler, and that they were particularly interesting and instructive when the tumbler was held at an angle to the horizon. He also found that by blowing through a tube on a plate of glass, a converse series of rings was obtained. And as a proof that these rings were formed of waves, we had merely to examine their motions—the motion of the one series was the converse of the other. Again, he took a thin disc of glass and laid it on another piece of glass of any thickness, and subjecting it to pressure and then cementing the pieces together at the edges, the rings were made permanent. He also showed how the parallel bands of colour could be imitated by prismatic refraction of white bands of the same ratio as to breadth.

The author then applied these laws to explaining the phenomena of the prism. He argued that all matter was put in motion by light, just as we were sensible that every atom of a body was moved by heat. He showed, not only by diagrams but mechanically, the physical laws by which light was refracted and reflected, and expounded, as he considered, the true theory of prismatic refraction. As—how a ray of light was always refracted towards the base of a prism, and how it could not be physically otherwise. Then from these laws he concluded—Given the molecular vibration of matter, given the dispersion of light. He consequently arrived at the conclusion that light no more passed through glass than does sound. If we could withdraw the ether from a glass globe, we could no more see through the glass than we could hear through it if the air were removed.

As to the ether being heterogeneous, we do not say the atmosphere is heterogeneous because one sound differs from another. Why should light, then, differ from sound? Why compound, when the same uncompounded air can convey as great a variety of notes as there are shades or varieties of colours? A prism no more analyzes light or the ether in motion, than an Æolian harp analyzes sound, or the air in motion, for light and sound are both merely modes of motion of two different elements. As a magnet conveys motions of one kind, so glass conveys motions of another, the one not more wonderful than the other. We surely consider the molecules of the magnet to vibrate. Why not the molecules of glass, and consequently of all matter refracting light? A telescope is but another kind of telegraph, only much more comprehensive in its range.

* Literary and Philosophical Society.

PELLET GUNPOWDER.

AN appendix to the March issue of the "Army Circular" gives a list of changes in artillery *materiel*, small arms, and other military stores, with instructions relating thereto. These lists of changes will in future be issued monthly, instead of quarterly as heretofore. The present list contains an order that pellet gunpowder is to be provisionally adopted for all gun charges of 50lb. and upwards. The difference between this and ordinary granulated powder is due to the fact that the composition, after having been converted into "meal" in the breaking-down machine, is pressed at once into cylindrical pellets instead of being made into "press cake" and then broken into grains in the granulating machine. The pellets are formed by the meal being placed in a number of holes in a metal plate, into which closely-fitting punches (having projections that form a cavity in the end of each pellet) are forced by hydraulic pressure, adjusted to give the density required. This is the method by which pellets for fuzes and blank ammunition for Snider rifles have long been made in the Royal laboratories. When the pellets are dry they are drummed for about half an hour with black lead to glaze them.

The following are the particulars of the powder provisionally approved:—

Range of density of the pellet	1.65 to 1.7.
Diameter of pellet ...	0.75in.
Depth	0.485in. to 0.495in.
Diameter of cavity or indentation in end of pellet	0.2in. at top. 0.15in. at bottom.
Depth of ditto	0.25in.
Range in weight of the pellets	85gr. to 95gr., *i.e.*, about 78 to the pound.

Pellet powder has been introduced in consequence of its exercising a materially less destructive effect on the guns than the present L. G. R. powder, than which it exerts a smaller maximum pressure. The repeated failures of 13-inch guns, only two of several of these pieces now remaining serviceable, was doubtless due to the destructive quality of this L. G. R. powder when used in very large charges; and, accordingly, the select committee, after instituting experiments with pellet powder, and comparing them with the results obtained in Russia and in America, recommended the introduction of this powder for the guns of the future, in which the charge would exceed 50lb. There are no guns larger than the 9-inch of 12 tons actually in the service as yet, though experiments have been made with a 10-inch rifled gun at Shoeburyness, and some 12-inch guns have been constructed during the last year; so that the introduction of the powder will be simultaneous with that of these heavier guns. We may, therefore, hope that no more large and costly guns will find their way to the list of those which have already yielded to the destructive action of our large grain rifled powder, which is far more powerful than that used by any other nation. Further experiments with pellet and prismatic powder are still in progress, and are likely to extend over a considerable period.

THE BOARD OF NAVAL SURVEY BILL.

DURING the American war a proposition was made in Congress to establish a "Board of Admiralty," analogous, in its general features, to the Board which it is now contemplated to create under the title of a "Board of Naval Survey," the leading features of which we have placed before our readers. The project failed from the strong opposition it encountered; and among its opponents was the United States "Army and Navy Journal," from which paper we take the following article. Says our contemporary:—To the bill now introduced into Congress we as unhesitatingly give our support, as we withheld it from its predecessor; and it will be an easy matter to show why a Board of Survey is expedient now, but was inexpedient several years ago. The Board of Admiralty bill was introduced at a critical period of the war. It was then no time for re-organization, for the emergencies of war were constantly pressing on the department. It was, perhaps, safer to make mistakes and suffer losses than to experiment with new projects. It was probable that before the Board could be well organized the war would come to an end, and it would require re-adjustment on the peace basis of the naval establishment. Blunders enough, it is true, had already occurred to justify the establishment of such a Board; but at that time the only question was as to what was needed for immediate use against the enemy, without distracting the attention of the department. These considerations no longer have any force. Peace has come, and with peace comes the necessity of providing that the blunders and follies of the late war be never again perpetrated. Take, for example, the "light-draught" business—a performance which a contemporary has, with just severity, pronounced an "engineering blunder without parallel in the annals of professional incompetency." These twenty nondescripts, which were to have been built for less than 400,000 dollars each, have already, it seems, cost 538,000 dollars, and the contractors declare that about 150,000 dollars additional will be required. For these fourteen millions what have we to show? Nothing. Twenty vessels "hardly worth their weight in old iron." They did not fire a hostile shot in the rebellion; their designs were so bad as to render them worthless; they are a disgraceful monument of naval inefficiency.

Who is responsible for this great blunder? The responsibility has been fixed nowhere. It has been trundled about from the shoulders of one man to the shoulders of another, and "nobody to blame," like the verdict on a railroad accident, it is all the satisfaction the country procures. Had a Board of Survey been in authority when these light-draughts were proposed, is it possible that these blunders would have been made? They certainly would not have been. The utter worthlessness of the designs was not only at the outset made the subject of criticism and remonstance by eminent contractors and engineers in the country, but their views were laid before the department. But nothing was done—whether according to the maxim that "what was everybody's business was nobody's business," or for some other cause, we cannot say. The ships were constructed according to the worst plans, and at localities where they could least easily render the services for which they were designed. Now, we have no disposition to reflect on the department in this matter. On the contrary, we may assume that their affairs were conducted with efficiency and honesty. But, if this is so, then the Board of Survey is an absolute necessity to the Navy Department. That this and similar blunders of the most glaring and costly character have been committed, and are still committed, nobody pretends to deny. And if we admit that the fault is one that could not be laid at the doors of the department, then it is a matter of logic that some new organization must be added to its working power. Such an organization is furnished by the Board of Survey; and the Navy Department, in view of the past blunders in construction, ought really, for its own vindication, to be the strongest advocate of such a Board. To conclude otherwise is to say that it is an unavoidable necessity that the country shall be ruined by incompetency and extravagance—a point which taxpayers will hardly concede. As it is now, owing to the conflicting views of the different bureaus, almost everything in the way of construction that comes from the Navy Department is an expensive failure. There was a minor instance of the same sort (involving, it is true, but a million of dollars), which we will mention, because we have never before alluded to it in the journal. The "Tonawanda"—whose construction was a favourite project with the Naval Bureau—was built in the Philadelphia Navy-yard. There could be no plea of want of supervision. It was built under the very nose, as we may say, of the constructional bureaus. It proved an utter failure, having failed in flotative power. Somebody made a mistake—whether in calculating the displacements or in crowding in the weights. It was a very simple arithmetical problem, but it was a failure. The only possible explanation is in a want of harmony between the bureaus. They evidently had no conception of what they were about, and each was content to do its own work, without reference to the other. In view of such a performance, it would seem but a vindication of their own character for these various bureaus to advocate a Board of Survey.

We could cite scores of instances of blunders, any one of which would be ground sufficient for the immediate establishment of some such Board as the one now proposed. The truth is, that some remedy for the enormous errors and follies of the past few years must be applied—and what other is proposed? Take, for example, our entire new screw fleet, representing millions upon millions of dollars. We have thoroughly exposed these astounding constructional blunders, which have made us a laughing stock to all European engineers of the highest skill. We believe this to be a subject which will bear ventilation. We publish arguments against the Board with as much eagerness as arguments in its favour. We are bound, however, to say that the leading argument urged against the Board seems to be founded on a grave misapprehension; and, when we explain it, much of the objection to the project may be overcome. It is feared that the Board of Survey is simply an adaptation in America of the British Board of Admiralty. This is quite erroneous. The Board of Admiralty is a political rather than professional body, and is liable to change with the Ministry. In other words, it has the same defects that result from our own system, where each new administra-

Digitized by Google

tion sweeps out all the bureau officers of its predecessor. Now, this fundamental objection is precisely the one we desire to avoid. We desire to establish a professional, not a political, Board—whose tenure of office shall be entirely independent of political considerations, and who shall devote their life-long energies to bettering the material of the Navy. The Board of Admiralty has been described as "an organization of the Ministry in the administrative department of the Navy." The Board of Survey would be a permanent and responsible Board of high professional navy officers.

TWISTED BARS.

WE have recently examined some samples of twisted wrought-iron bars which combine the four great essentials—strength, lightness, elegance, and cheapness. These bars are largely manufactured by Messrs. Macnaught, Robertson, and Co., of 5, Bankside, Southwark. The bars are drawn from the rolls in the cruciform section, and and twisted hot, so that the fibre of the iron is not injured. A regular twist of pleasing appearance is produced, two bars in some patterns being twisted together. The various sizes and patterns are well adapted for the purposes of ornamental ironwork in general. Although very light, these bars possess considerable strength, as will be seen from the following results of tests to which Messrs. Macnaught and Co. have submitted them.

Correspondence.

THE PATENT OFFICE LIBRARY.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—I crave the use of your columns for the purpose of calling attention to the condition of the public library of the Commissioners of Patents, in Southampton-buildings. This collection of scientific works, perhaps the finest in Great Britain, containing upwards of 46,000 volumes, is the resort of large numbers of persons whose labours as literary men, inventors, &c., are practically beneficial to the whole of the community; and there can be no manner of doubt, that if it were more widely known to be free of access to the public it would be at all hours in the day most inconveniently crowded with readers. The present library rooms have been but recently built in the top of the house. They afford accommodation the most ample that can be hoped for, so long as science shall be elbowed by law into out-of-the-way offices and an attic floor. It is not surprising, therefore, that books are now again to be seen in gathering heaps upon the tables; and the cheerful prospect is held before students of science that some of the works they may need for reference must speedily be searched after in cellars, and, as Diogenes groped for his "honest man," with a lantern.—I am, Sir, yours, &c., J. T. DEXTER.

Public Museums and Free Libraries Association, 150, Strand, W.C.
March 25.

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith.—ED. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

RECEIVED.—M. H.—G. L.—T. C.—Messrs. M. and T.—G. H. D.—G. E. P.—Messrs. K. and K.—G. J. G.—M. E.—J. T. D.—J. T. D.—F. W. B.—A. E. S.—T. W.—A. K.—J. B. T.—R. C.—A. C.—G. H. D.—A. W.—W. H. H.—Messrs. D. and M.—G. W. H.—J. M.—J. N.—S. M.—R. S.—F. W. B.—R. T.—Messrs. K. and K.—E. F. S.—R. T.—A. R.—G. W. H.

THE number of visitors to the Patent Office Museum, South Kensington, for the week ending March 28 was 3,587; total number since the opening of the museum, free daily (May 12, 1858), 1,267,629.

Meetings for the Week.

MON.—Royal Institution.—General Monthly Meeting, at 2 p.m.

Society of Engineers.—Mr. Sydney A. Reade, M.A., on "The Sewerage Works at Redhill," at 7.30 p.m.

TUES.—The Institution of Civil Engineers.—1st, Discussion on "The City Terminus Extension of the Charing Cross Railway;" 2nd, Mr. W. Airy, A.I.C.E., on "The Experimental Determination of the Strains on the Ties of a Bow-String Girder," at 8 p.m.

Naval, Military, and Gunnery Items.

OWING to unavoidable circumstances, the First Lord of the Admiralty's levee, announced for the 7th instant, will not be held.

SIR WILLIAM MUIR has drawn up a minute with the object of demonstrating the inexpediency of the Home Government requiring the gratuitous supply of Indian troops for the Abyssinian Expedition, it being a dangerous precedent.

THE annual course of musketry instruction commenced on Wednesday last at Aldershot, and will be continued during the season. A medical officer is detailed for duty at the ranges every day, unless musketry instruction be suspended by any interrupting circumstance.

The ship "City of Melbourne" was burnt at the Williams Town Railway Pier on January 25 last. She was a fine vessel of 1,828 tons burden. She had a portion of her cargo for England on board, among which it was supposed might have been some damp wool, causing spontaneous combustion. A coroner's inquiry has thrown no light on the origin of the fire.

WITHIN the last few days the whole of the steamers and sailing ships of war attached to the reserve ordinary at Chatham have been removed from the harbour to Stangate Creek, where they are moored with the other vessels of the reserve squadron, in three divisions, until the Lords of the Admiralty have finally decided as to their ultimate disposal. In a few days Chatham will be without a single vessel of war in its harbour—a circumstance that has not occurred for some centuries.

WE hear that the Government are about to contract with Captain Hugh P. F. Palmer, late of the yatch "Warhawk," for the removal of the top of Daunt's Rock. Captain Palmer has had considerable experience in submarine engineering, and in this contract it is said will employ some new machinery which he has adapted for the work, and by the use of which the services of divers will be very little required. There is about half a million tons of solid rock to be removed, all of which is under water.

The Board of Trade have determined to present honorary certificates, illuminated and engrossed on vellum, to Pierre Eleonor Mulard, pilot; Jacques Auguste Dutertre, pilot; and Jean Adolphe Delannoy, coxswain, who, together with ten seamen, manned the Calais life boat on the occasion of the rescue of the crew of the schooner "Forester," of Ryde, on December 2, 1867. The service was one of much gallantry and danger. Pecuniary rewards have been given to the rest of the crew.

THE "Cracker," twin-screw gunboat, composite built, was recently put through a trial of her speed over the measured mile in Stokes Bay. She drew 7ft. 2in. forward, and 8ft. 2in. aft. Condensing she realized a mean speed of 10·423 knots, and under high pressure a mean speed of 10·212 knots. The machinery of the "Cracker" consists of two sets of engines, by Maudslay, Sons, and Field, taken out of two condemned gunboats of the old class. They worked very satisfactorily, and the boilers generated an abudant supply of steam.

THE "United Service Gazette" records the following gallant act which we gladly reproduce. A little after midnight on February 20, in the middle of a heavy thunderstorm, a marine of her Majesty's ship "Royal Alfred," at Bermuda, blinded by the lightning and rain, walked overboard. Navigating Lieutenant Kiddle, and a corporal named Parsons, jumped overboard and succeeded in reaching him as he was sinking. With difficulty, owing to the intense darkness of the night, they succeeded in swimming with him to the landing place.

SIR JOHN PAKINGTON, as Secretary of State for War, has nominated the following gentlemen to act as a committee to inquire into the character and construction of our coast defences, whether of iron, masonry, or earthwork, as recommended by the Royal Commission on National Defences:—Admiral the Hon. Sir F. G. Grey, G.C.B., Chairman; Major-General Collingwood Dickson, C.B., Royal Artillery; Major-General Simmons, C.B., Royal Engineers; Major-General Harness, C.B., Royal Engineers; and Mr. Hawkshaw, C.E. It is presumed that an officer of the Royal Engineers will be selected as secretary.

A CONTRACTORS' trial of the engines of the gunvessel "Lapwing," lately took place outside Plymouth Sound. She is of 663 tons burden, and belongs to the new class, of which there are eight vessels, and was constructed at Devonport. The "Lapwing" is the first of the four tried, and she is supplied with two pairs of engines by Messrs. Rennie to work her two propellers. The mean of six runs, at full power, gave a speed of 10·46 knots at a mean number of 116 revolutions per minute, the mean pressure in boiler being 26lb. The vacuum 25in., giving an indicated power of 830 horses, being five times the nominal power, 160, and 110-horse power more than the contract indicated power. These engines are of the ordinary type, without surface condensers or superheaters, and were tried under the regulations recently issued by the Admiralty. The result may, therefore, be considered satisfactory. The mean speed at half-boiler power was 8·06 knots, the revolutions 97, and pressure of steam 19lb.

Miscellanea.

WE are glad to see that there is at length a prospect of the passengers to London by the South-Western Railway being admitted to direct access to the City by the Charing Cross and Cannon-street line.

THE Minister of the French Emperor's Household and of the Fine Arts has appropriated a sum of 400,000f. for the reconstruction of the tower of the Cathedral of Notre Dame d'Arras.

A NEW cloth factory has commenced operations at Geelong. It is the first factory of the kind established in Victoria. A paper mill is now nearly completed on the banks of the Yarra, and is probably in full working order by this time.

THE committee appointed to report upon the construction of the bridge over the Hooghly, to form a junction between the Great Indian and Eastern Bengal Railways, is favourable to the Government plan, a new company undertaking the work.

THE surveying ship "Hydra" has arrived at Aden, having been engaged in taking the line from Aden to Bombay for the projected submarine cable. The greatest depth obtained between Bombay and the island of Kooria Mooria is 2,080 fathoms.

ON Wednesday last, a deputation from the Royal Agricultural Society waited upon the Prince of Wales with the request that his Royal Highness would act as president of the Society during the ensuing year, to which the Prince consented.

THE visitors to the South Kensington Museum during the week ending March 28, were, on Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 10,599; on Wednesday, Thursday, and Friday (admission 6d.), from 10 a.m. till 5 p.m., 1,680; total—12,279. Average of corresponding week in former years, 10,914; total from the opening of the Museum, 7,267,637.

THE total imports of Australian gold within the last ten years have been as follows:—1858, £9,064,763; 1859, £8,624,566; 1860, £6,719,000; 1861, £6,331,225; 1862, £6,704,753; 1863, £5,995,368; 1864, £2,656,971; 1865, £5,051,170; 1866, £6,839,674; and 1867, £5,801,207. Upon the whole the gold-yield of Australia would thus not appear to be making progress, although the deliveries are still considerable.

SAYS the Austrian correspondent of the "Telegraph," "I hear that Count Edmond Zietry has really got the concession for the Oriental Railway (Stamboul, Adrianople, Sophia, Tatar-Bazar, Novi-Bazar, with branches to Onos, Salonica, and Varna) from the Porte, and that a firman to that effect will soon be issued. London to Constantinople in three days eighteen hours? What will Mrs. Partington say to that, I wonder?"

THE increase in the imports of cotton from the United States this year has been very great, 792,336cwt. having come to hand from that quarter to February 28, as compared with 486,415cwt. in the corresponding period of 1867, and 570,735cwt. in the corresponding period of 1866. British India, however, sent us only 102,539cwt. of cotton to February 28 this year, as compared with 96,500cwt. to the corresponding date of 1867, and 305,907cwt. to the corresponding date of 1866.

MESSRS. BELL AND DALDY have in preparation a volume of Scotish scenery, containing views of many of the places of interest visited by her Majesty and the Prince Consort, accompanied by descriptive letterpress, with an essay on the characteristics of Scottish scenery, by a popular writer. The illustrations are exquisite sun pictures, taken by a process discovered by Mr. Joseph Adam, who has been engaged many years in bringing it to perfection. By this invention the photographs have all the soft appearance of the finest line engravings, and are works of a very high class.

AN explosion of a serious character lately took place at the carriage works of the North of England Railway Company, the Marsh, Preston. A number of workmen were employed on a large casting, and when they had got about six tons of metal in, an explosion took place, caused by the splitting of a core. A current of air got between the cinder bed and the core, which forced the metal out, scattering it about the shed in all directions; sand and other *débris* was thrown into the room above. A workman who was standing on a crane was blown off; and four others were severely injured by the hot metal.

AT Melbourne an address was presented to the Duke of Edinburgh by Victorian colonists of not less than a quarter of a century's standing. Though the time for signing the address was short, it had

Digitized by Google

more than 600 signatures, twenty-four dating back their residence in the colony to 1836 or earlier, two to 1834. All the signatures have been photographed for preservation. Mr. Henty, the oldest Victorian colonist, read the address. The Hon. J. P. Fawkner informed the Prince that he was in Port Phillip in 1803, and that he was the oldest inhabitant of Melbourne, where he settled in 1835, one year after Mr. Henty settled at Portland.

THE Royal Horticultural Society is this year extending its exhibitions of spring flowers, by the plan of allowing the leading nurserymen to make displays of the specialities they cultivate. On Saturday, Mr. William Paul commenced his show. The leading features are a mixed bank of forced hardy trees and shrubs, hyacinths, tulips, roses, the new double crimson thorn, standard variegated geraniums, &c. One hyacinth, of a yellow shade, called "The Bird of Paradise," has no less than eight spikes of flowers, and plants of the Erica Willmoreana have spikes 18in. long. There was a large and fashionable attendance. The band of the 1st Life Guards performed selections of music during the afternoon.

FOR some time past the Conservative party has reckoned on having as one of its representatives for the borough of Bedford Mr. James Howard, so well known to the agricultural and engineering world, and last year presented a requisition, numerously signed, calling on him to stand as a candidate. Mr. Howard, though a traditional Tory, declined the invitation; among other reasons, on the ground that his views on many important political topics were much in advance of those avowed by the party. Notwithstanding this reply, it was generally hoped that Mr. Howard's scruples would be overcome. So far from that being the case, however, the subsequent policy pursued by the Government has determined Mr. Howard to withdraw altogether from the Conservative party and to join the Liberal ranks.

THERE are sixty-three manufactories of beet-root sugar in Lithuania, Podolia, and a part of Bessarabia, of which half are also refiners. The smallest use from two to four presses, the largest twenty-two. 3,200,000 hectolitres of beet-roots are bought for the manufactories. The largest manufactory belongs to a company of shareholders, who buy the beet-roots of the neighbouring proprietors, and beet-roots generally realise 3fr. 50c. the korsee, a measure equivalent to 1 hectolitre 28. Nearly 9,000 workmen are employed, whose wages amount to about sixteen millions of francs. Almost all the sugar not consumed in the country is sold to Russia. There are 1,428 distilleries, in which a large number of workmen are employed, and their manufacture represents the value of eighty millions of francs.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

BOILERS AND FURNACES—2520, 2557, 2562
BUILDINGS AND BUILDING MATERIALS—None.
CHEMISTRY AND PHOTOGRAPHY—2522, 2524, 2546, 2548, 2549
CULTIVATION OF THE SOIL, including agricultural implements and machines—2507, 2508
ELECTRICAL APPARATUS—None.
FIBROUS FABRICS, including machinery for treating fibre, pulp, paper, &c.—2510, 2518, 2527, 2533, 2551, 2552, 2560
FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—None.
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c—2529, 2576
GENERAL MACHINERY—2503, 2509, 2515, 2523, 2525, 2520, 2537, 2540, 2565, 2566, 2569, 2572
LIGHTING, HEATING, AND VENTILATING—2531, 2577
METALS, including apparatus for their manufacture—2541, 2553, 2568, 2571
MISCELLANEOUS—2505, 2512, 2514, 2516, 2521, 2538, 2539, 2542, 2544, 2554, 2559, 2561, 2563, 2564, 2567, 2570, 2574, 2575, 2578 2579
ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—2511, 2517, 2519, 2526, 2532, 2543, 2558, 2573
SHIPS AND BOATS, including their fittings—2506, 2528, 2534, 2545, 2555
STEAM ENGINES—2535, 3536, 2556
WARFARE—2502, 2513, 2547, 2550

2500 H. G. GRAHAM. *An apparatus for heating, boiling, agitating, and raising size and other liquids.* Dated September 4, 1867.

This invention is carried out in the following manner:—First, the patentee takes a straight tube of copper, &c., and around the outside of that he winds, in a spiral form another tube, or what will, when attached, form a spiral tube. Through the exterior or spiral tube he passes the size or fluid to be heated or boiled, and into the interior or straight tube he passes steam or heated air which will heat or boil the aforesaid size or fluid. Second, in another form of the apparatus he takes two spiral tubes, one within the other. Through the exterior tube he passes the size or fluid to be heated or boiled, and into the interior tube he passes the steam or heated air which will heat or boil the size or fluid. Third, in another form of the apparatus he takes either of the two before-mentioned forms of apparatus, and encloses it in a steam-tight cylindrical vessel, taking care to arrange one or more small tubes communicating from the interior of the cylindrical vessel to the innermost tube. Into this cylindrical vessel and innermost tube he passes the steam or heated air, and through the other tube he passes the size or fluid to be heated or boiled by the steam or heated air. Fourth, if he wishes to raise or agitate the size or fluid, any of the before-mentioned forms of apparatus are placed and made to revolve in the manner of an Archimedian screw, which raises, and, at the same time, agitates the size or fluid.—Patent abandoned.

2501 W. WELDON. *Improvements in the production of artificial oxides of manganese, and in the manufacture of chlorine by means thereof, partly applicable also to other purposes.* Dated September 4, 1867.

The patentee claims the use of ozonized air for the peroxidation of low oxides of manganese, whether in the wet way, or in the dry way, the various methods of procedure, whether using ozonized air or ordinary air, and likewise the various details of apparatus, &c., all as set forth, and the air for the purposes indicated of artificial oxides of manganese peroxidized and otherwise produced and treated, as described.—Patent completed.

2502 G. W. HOWARD. *Improved apparatus to be used in the manufacture of ball cartridges.* Dated September 4, 1867.

The object here is to provide a small portable apparatus for fixing or cramping the ball or bullet into the metallic cartridge case known as the "Boxer" cartridge case. The bullet used with this kind of cartridge case is of a cylindro-conoidal form, the cylindrical part having circumferential grooves for the reception of the lubricating material or compound. This part is slipped into the mouth of the thin metallic cartridge case containing the powder, and is fixed therein by pressing or cramping the cylinder of thin metal into one of the grooves of the bullet. The apparatus which the inventor employs for this purpose consists of a case having a partially cylindrical groove of a suitable form and size to receive the cartridge case. At one end of this groove (and at right angles thereto) is a gauge plate having a circular hole to receive the conical part of the bullet. Attached by a joint to the base is mounted a lever (lying also at right angles across the groove) provided with a concave notch. The form and position of this lever are such that, when it is raised a charged cartridge case with the bullet inserted in the mouth is laid in the groove and pressed forward until its conical fore end fits into the hole in the gauge plate; the notch in the lever is exactly over one of the circumferential grooves. Pressure is now applied to the lever with one hand, whilst the cartridge is rotated with the other, which will have the effect of cramping or indenting the thin metal case into one of the circumferential grooves of the bullet, so as to attach the same firmly thereto.—Patent abandoned.

2503 F. B. DERING. *Improvements in machinery for boring, cutting, or working in rock, coal, and other mineral.* Dated September 4, 1867.

This invention relates, first, to an arrangement of machinery for undercutting or cutting a groove in rock; and, second, to engines and carriages or stands specially applicable to coal cutting. The main feature in the arrangement for undercutting or groove cutting is the combination of a longitudinal travel and a transverse travel given to the engine and cutting tool. The second part of the invention relates to arrangements of engines and carriages or stands specially applicable to coal cutting. The chief features of the arrangements are that the coal is chipped or cut by a series of blows, the cylinder advancing in the direction of its length at the end of each blow, or as required, according to the work done, and when it has reached the end of its travel on the cradle it is returned to its original position by another cylinder, and the carriage on which the engine is carried is moved laterally to commence a fresh cut. During the moving back of the cylinder to commence a fresh cut the piston is prevented from working. Reference to the drawings is essential to a full description of the invention.—Patent completed.

2504 J. K. SMYTHIES. *Carrying passengers through the air by a steam bird or flying steam engine fitted with wings flapped by the action of steam.* Dated September 4, 1867.

Here the patentee makes no claim to any separate part of the mechanism described, and he does not confine his claim to the details described, which may be varied, but he claims combining mechanism into a steam bird or flying engine with wings flapped by the action of steam, capable of carrying passengers through the air. We cannot here produce the details of the invention.—Patent completed.

2505 F. H. and J. W. H. PATTISON. *Improvements in a new or improved metal-founders' blacking.* Dated September 4, 1867.

This invention consists in the manufacture and use of a new metal founders' blacking, used for coating the inner surfaces of moulds and cores which receive the molten metal, and which imparts a fine skin or outer surface to the castings formed therein, formed mainly of "anthracite" or "blind" coal, known as a coal which emits little or no gas or flame in burning (and which has heretofore been used or employed for making such moulders' or founders' blacking); to this the inventors add a small proportion of fireclay, wood charcoal (by preference that formed from oak), animal charcoal, or the hard residuary carbon or coke from mineral oil refining stills, which latter is, in some cases, further calcined or burned in close retorts before being used.—Patent abandoned.

2506 G. T. BOUSFIELD. *Improvements in paddlewheels for water craft.* (A communication.) Dated September 4, 1867.

What is claimed as the improvement in paddle wheels having paddles capable while in action of varying their inclinations to the radial arms of the paddle-wheel frames, is the combination of the controlling frame of the paddles with the paddle guard by means of a flexible connection, substantially as set forth. Also the arrangement of the connection diagonally to the vertical and horizontal directions in which the paddle guard is moved by strains, substantially as set forth. Also the arrangement of the radial lines of the paddle crank arms and the radial lines of the flexible connection at equal angles with a vertical line, substantially as set forth. Also the combination of the controlling frame of the paddles, paddle guard, flexible connection link, and paddle shaft, substantially as set forth.—Patent completed.

2507 J. HOWARD and E. T. BOUSFIELD. *Improvements in machinery for cutting grass or corn.* Dated September 4, 1867.

This invention is not described apart from the drawings.—Patent completed.

2508 G. A. BUCHHOLZ. *Improvements in machinery for hulling wheat and manufacturing semolina.* Dated September 4, 1867.

This invention is not described apart from the drawings.—Patent completed.

2509 R. A. JONES and J. C. HEDGES. *Improvements in fire-escapes.* Dated September 5, 1867.

This invention has reference to those fire-escapes which have for their principal features of construction the adaptation of wire or other ropes, cords, or chains wound upon a drum of such like contrivance (to be unwound therefrom when the fire-escape is in use), and the invention consists in the use of the following arrangements:—The ends of friction bands to be used with the cords, ropes, or chains are to be made with lugs provided with a collar or box that has a binding screw with a spring coiled around it acting against such lug, and for the other lug a lever with handle centred in the collar or box, the end being allowed by a slot through the same to be pressed against the other lug. Or, in place of the frictional arrangement just described, they would sometimes adopt the following:—Within the case containing the rope, cord, or chain they have pulley wheels so arranged that the chain, cord, or rope may be taken in a serpentine course over them, thus causing resistance to the unwinding of the rope, cord, or chain, the friction band being arranged to work on the edges of the holder of the chain, cord, or rope, instead of having a separate pulley, and is provided with a crank lever handle so disposed as to be easily accessible.—Patent completed.

2510 A. C. HENDERSON. *Improvements in the manufacture of applique embroidery on tulle, muslin, or similar fabrics in various colours and designs.* (A communication.) Dated September 5, 1867.

This invention consists in working on a ground of coloured net, or other substance, pieces of muslin or similar material of any desired colour to form various designs, the articles thus manufactured being intended for window curtains, blinds, hangings, furniture coverings, and other purposes.—Patent abandoned.

2511 W. H. KITSON. *Improvements in railway wheels.* Dated September 5, 1867.

This invention consists of certain modes of securing the tyre of the wheel to the inner frame or centre of the wheel. One of the chief objects the patentee has in view is to so secure the tyre that more of the thickness of the tyre may be taken for wear than is practicable by the previous methods in use, and also so to secure the tyre that, in case of its breaking, the whole shall be held firmly together. One plan for effecting this object is as follows:—He forms a flange all round the inner circumference at or near the outside edge of the tyre, which flange may be made plain, or with a groove or dovetail inside. Having placed the wood or iron centre of the wheel in position in the tyre, he secures them by a loose ring furnished with a lip or flange fitting into a groove or dovetail formed at the inner or flanged side of the tyre; to secure the whole, he passes a sufficient number of bolts or rivets through the fixed flange on the tyre, the wood or iron centre, and the loose ring; or he can reverse this arrangement by forming the fixed flange on the inner circumference of the tyre, at or near the flanged side of the tyre, and letting the flange or dovetail of the loose ring fit into the outer edge of the tyre, and securing it in the same manner as in the last-described arrangement.—Patent completed.

2512 L. B. POTHIER. *Improvements in fastening or securing metal bands or hoops on cotton and other bales.* (A communication.) Dated September 5, 1867.

Here one of the ends of the band or hoop is bent into a plane parallel to the unbent portion, so as to form a hook, and the band or hook is passed around the bale in the usual manner, while the bale is under pressure in the cotton or other press. Upon the hook of the band a flat ring is placed, one end of the ring being situated against the end of the hook at the junction of the latter with the band or hoop. The other end of the band or hoop is next passed through the ring described, and its extremity bent around the end of the ring into a plane parallel with the ring and the band or hoop from which it was bent. A second hook is thereby formed. The extremities of the band or hoop are thereby bent in opposite directions, and the hooks thus formed bear respectively upon the opposite ends of the flat ring placed between them. The hooks or terminating portions of the band or hoop extend some distance on either side of the ring, the terminating portions being at least eight inches in length. When the bale is released from the pressure to which it has been subjected in the press, its expansion causes the hooks to bear with great firmness upon the opposite ends respectively of the ring, and at the same time the pressure which is exerted at right angles to that described presses the projecting ends of the hooks outwards, and binds them firmly against the band or hoop from which they were made.—Patent abandoned.

2513 H. CARTER and G. H. EDWARDS. *Improvements in breech-loading firearms.* Dated September 5, 1867.

This invention relates to that description of arm which closes with a sliding rotating bolt with projecting hand lever, for which letters patent were granted to the present patentees, September 20, 1865 (No. 2417), and consists, first, in leaving the back end of the breech, as also the lever slot, open for the ready withdrawal of the bolt when required for cleaning or otherwise, and in applying a cap or cover to the hinder part of a gun, which cap completely covers in the groove in which the sliding bolt works, with the exception of the opening necessary for the introduction of the cartridge, and for the necessary traverse of the hand lever of the sliding bolt. This cover is rounded, and partly follows the shape of the gun, its hinder part being carried a little way down the neck of the stock, tapering off, and forming a part thereof. In adjusting the cover it is slid on the shoe of the gun from the breech end, two projections disposed one on either side in the interior of the cover taking into grooves made longitudinally in the shoe, by which the cover is held closely down thereon. The whole is secured in place by a screw passing down through a projection formed under

Digitized by Google

the tapered part of the cover, and screwing into the tail-piece of the shoe. This tail-piece has also a recess formed in it which, when the cover is pushed forward in place, receives the lower part of the above-mentioned projection, and through which the screw passes, thus firmly fixing the cover, and preventing all movement thereof until the release of the said screw. When it is desired to withdraw the bolt from the gun it is simply necessary to release the screw in order to take off the cover; the bolt is then free to be withdrawn from the gun. The invention consists, second, in combining the trigger and sear together so as to form but one piece. The sear may be shortened, while the trigger projects from the under side thereof, thus obviating the necessity of a separate fulcrum for the trigger, and rendering the action of the lock quicker. A third improvement consists in fitting the extractor applied to such guns so that a dovetailed end recessed into the sliding bolt shall be received in an undercut and dovetail recess when the bolt is drawn backward, so as to prevent its falling from the bolt when it is withdrawn at the breech.—Patent completed.

2514 G. COPE. *Improved apparatus for pressing and shaping cigar bunches.* Dated September 5, 1867.

This invention consists of two frame-pieces made of wood, &c., so fitted with projections and recesses on their faces, that, when they are placed together into the positions they occupy when giving pressure for either shaping or pressing, a number of moulds or openings are left between them, each one an exact negative of the shape of the cigar the apparatus is designed to produce. The recesses on one of the frame-pieces are formed by and between projecting sliding blocks, the face sides of which project like the teeth of a rack. These blocks slide on feathers or ribs secured to the frame; they are coupled together by a flexible or elastic band, by which they can be separated from each other a short distance. The recesses on the other frame are the spaces between stationary projections.—Patent completed.

2515 J. FORD. *Improvements in means for securing wheels, pulleys, cranks, and other articles on their shafts or axles.* Dated September 5, 1867.

When applying this invention to securing railway wheels on their shafts or axles the patentee keys the wheel on to the axle as usual, and forms a recess in the nave or boss to receive a ring flush with the outer face of the nave or boss, and he forms a shallow groove in the shaft or axle corresponding with the recess in the nave or boss of the wheel, the outer end of the key being made flush with the shaft or axle, and with the shallow groove. He then passes a ring previously heated over the end of the shaft or axle, and forces it into the recess in the nave or boss of the wheel; this ring on cooling shrinks within the shallow groove formed in the shaft or axle, and thereby firmly secures the wheel thereto, the wheel being thus held between the shoulder on the shaft or axle and the shrunk ring, which becomes firmly secured to the shaft or axle, and at the same time holds the key firmly in position.—Patent completed.

2516 J. S. HENDERSON and J. MACINTOSH. *Improvements in the manufacture of metallic cases or canisters, and in the machinery or apparatus employed therefor.* Dated September 5, 1867.

This invention has reference to a former patent, dated July 11, 1867 (No. 2033). Under the present invention, after the cylindrical part of the canister is formed, the bottom is placed either on it or into it, and the cylinder, together with the bottom, are placed upon a revolving platform or stand, which is put in motion either by manual or other motive power. The parts to be soldered have a ring of solder placed on or in them, and a heated bolt or jet of flame from a compound or other blow-pipe is brought to bear upon the solder or part to be soldered, and the solder as soon as melted fills into the spaces between the end or ends and body of the canister, and effectually joins these parts. After the canisters are filled, the cover is soldered to the body of the canister in a similar manner.—Patent completed.

2517 G. H. PIERCE. *Improvements in padding for horse collars, saddles, and harness.* Dated September 5, 1867.

Here the padding is effected by air contained in a cushion or bag of suitable form made of air-proof material.—Patent abandoned.

2518 E. BERNHEIM, G. W. WILSON, and E. LONGWORTH. *Improvements in the treatment and method of preparing printed warps.* Dated September 5, 1867.

This invention consists in treating the warps so as to produce a "chene" or intermixed effect when in the extended or "warp" state, and not in "hanks," and the method of preparing such printed warps is as follows:—The warps, either plain or dyed, are first "leased" as usual—that is, divided into sections widthwise, such sections being kept separated by transverse rods or battens, and the warp in this divided and extended state is printed upon by any ordinary suitable method, and after such printing every other divided section alternately, or such of them as may be desired, is "drawn up" a greater or less distance (the rods allowing the sections to slip), so as to displace the regularity of the printing, in which state it is afterwards used in weaving.—Patent abandoned.

2519 J. B. HANDYSIDE. *An improved construction of railway buffer.* Dated September 5, 1867.

This invention relates to a novel arrangement of buffer in which a floating piston for transmitting and distributing the pressure of the coiled springs is used in combination with a telescopic arrangement of case. The invention cannot be described without reference to the drawings.—Patent completed.

2520 A. V. NEWTON. *Improvements in the construction and fitting up of safety valves for steam boilers or generators.* (A communication.) Dated September 5, 1867.

This invention relates, first, to safety valves which are formed with a surface outside of or beyond the ground joint for the escaping steam to act against, and keep them open until the pressure of the steam in the boiler shall have fallen below the pressure required to open such valves. It is now proposed to apply to such valves means of regulating or adjusting the area of the aperture for the escape of the steam beyond the surface outside of the ground joint, so that the valve may be set to be closed by any desired pressure below the pressure required to open it. The invention further relates to means for preventing the guides and stem of a valve controlled by a spring from binding, and thereby impeding the movements of the valve; and this part of the invention consists in making the pintle or stem which receives the tension of the spring bear on the valve so far below the plane of the valve seat that the force of the spring shall always be communicated to the valve in the direction of its axis. The invention also relates to an improvement by which the loud noise produced by the sudden opening of a safety valve is materially reduced, which noise is very objectionable, particularly on locomotive engines, and which is due to the fact that, when first opened, the valve is thrown up too high above its seat, and with great force. The improvement consists in combining with the valve and its seat an adjusting screw so located that, when the valve is forced up, its stem comes in contact therewith, and prevents the valve from being opened beyond the extent required for the relief of the boiler. The last part of the invention relates to means by which the valve can be adjusted to open at any required pressure, and then enclosed and locked up so that the adjustment cannot be changed except by the person having charge of the key.—Patent completed.

2521 H. GARDENER. *Improvements in connection with miners' safety lamps.* Dated September 5, 1867.

This invention is designed to supply such a fastener or lock to lamps similar to "Davy" lamps for mining purposes that, when once lit and closed, it cannot again be opened without first destroying the efficacy and utility of the illuminating properties of the lamp, and the invention consists in the application of a tube for wick or "duct" for feeding the lamp with oil that is separate and detachable from the body of the lamp, the tube being constructed so as to form a plug, &c., that will prevent the escape of oil when forming a portion of the lamp, and that will also, when screwed to its seating, form a bolt or lock that will prevent the gauge or protecting cover being removed so long as the lamp is employed as an illuminating medium.—Patent completed.

2522 F. VERSMANN. *Improvements in the manufacture of varnishes.* Dated September 5, 1867.

This invention relates to the use of certain solvents for the gums, resins, or gum resins employed in the manufacture of varnishes, and it is particularly applicable in obtaining solvents of copal for that purpose. The solvents employed are these:—Alcohols of the series represented by the formula $C\,n, H\,2\,n + 2 : 0$ ($C = 12$), containing more than two equivalents of carbon, beginning therefore with propylic alcohol $= C\,3, H\,8 : 0$. The mixture of some of these alcohols, known as fusel oil, which contains chiefly anylic alcohol, answers the purpose very well.—Patent completed.

2523 N. SEWARD. *Improved means and apparatus for producing motive power.* Dated September 6, 1867.

Here the inventor proposes to use the sea, lake, pond, or river, or he constructs a reservoir or tank containing water, mercury, or other suitable fluid, in which fluid is immersed an air vessel descending to any desired depth, the bottom of which air vessel is open, while it is closed at the top. Communicating with the top of this air vessel is a pipe provided with a cock or valve through which air or gases under pressure are forced, either by pumps, or by the combustion of explosive compounds, into the upper part of the air vessel; a syphon tube also passes through the top of the air vessel, and descends in the fluid nearly to the bottom of the air vessel, which tube has a cock or valve to the bottom thereof, while the external leg of the syphon, also provided with a cock or valve, passes to a turbine, water wheel, or other motive power engine capable of being worked by the flow or pressure of the fluid. The pressure of the air or gas inside the vessel causes the water or other fluid to pass through the syphon on to the motive power engine, thus producing motive power available for industrial purposes, part of which power is employed in conveying the fluid passing from the engine back into the sea, reservoir, or tank, by a pump or other suitable apparatus for raising fluids.—Patent abandoned.

2524 S. CASSAN. *The purpose of affording instant relief to persons afflicted with asthma, or subject to any other affections of the lungs or chest.* Dated September 6, 1867.

Here the inventor makes use of ordinary filtered paper in sheets or strips, which paper is then prepared by simply dipping it (but merely sufficient so as to damp the same) into the following chemical preparation. In order to prepare, say, 500 sheets of this filtered paper, he makes use of one half gallon of pure water, one pound (avoirdupois) of saltpetre, half a pound of alum, and one ounce of essence of bergamotte, and afterwards he hangs up the papers, or exposes the same in the air till dried, when they will be fit for immediate use by the patient. The mode of use is by lighting and burning half a sheet of such paper, and inhaling the smoke arising therefrom.—Patent abandoned.

2525 T. HODSON, W. MATHER, and J. RISLEY. *Improvements in lubricating shafts and other similar frictional surfaces.* Dated September 6, 1867.

This invention consists in the use of a chamber or cavity within the lower part of the bearing to contain lubricant, which is transferred or supplied from the chamber to the shaft by a cylindrical roller of cork, felt, flannel, leather, &c. This roller is mounted on a spindle, and slightly projects through an aperture in the bearing, so as to be lightly in contact with the shaft, so that the revolution of the shaft causes the revolution of the roller, and the lubrication is thus effected by self-acting means.—Patent abandoned.

2526 W. G. CREAMER. *Improved apparatus for excluding dust from railway carriages.* Dated September 6, 1867.

This invention consists in the attachment to the windows of railway carriages of jointed wire gauze screens or blinds constructed to fit into the same grooves in which the sashes are held.—Patent completed.

2527 T. W. HELLIWELL. *Improvements in looms for weaving.* Dated September 6, 1867.

This invention is not described apart from the drawings.—Patent completed.

2528 A. M. CLARK. *Improvements in the construction of ships and other vessels.* (A communication.) Dated September 6, 1867.

This invention consists in joining together two hulls by so placing them one above the other that the lower one of smaller dimensions than the upper shall be entirely immersed in the water when the ship is freighted or ballasted. The sides or bottom of the upper hull project on each side of the lower hull in consequence of its increased breadth, its bottom being at the level of the water line of the lower hull, the weight of which in the water will be very much diminished, at the same time giving the ship the draught desired.—Patent completed.

2529 J. G. TONGUE. *Improvements in the manufacture of garments for male and female attire.* (A communication.) Dated September 6, 1867.

This invention relates to the manufacture of body garments either for under or outer wear, such as skirts and mantles, or cloaks, whole or in one piece, by felting the material of which they are composed, and giving the article during the felting or "planking" process its desired form or shape ready for use, or so that it will only be necessary to split or cut it open to make a skirt or cloak complete without basting or separate felting of parts together, only if desired trimming it or binding the edges whole or in part and attaching suitable fastenings thereto.—Patent completed.

2530 T. COOK. *Improvements in sewing machines.* Dated September 7, 1867.

As regards the driving gear, this invention consists of a worm wheel and two worms or askew gear mounted on axes working in one end of a suitable casting, the other end carrying the needle bar, and other parts. The worm wheel is placed in a line with the casting, and the worms are situated one above and the other below the centre of the worm wheel; the upper worm is for working the needle bar and feed, and the lower worm for working the looping motion, which may be effected as follows:—The upper worm is fixed thereon with a cam formed on the back thereof; this disc is embraced by the circular recessed part of a rocking or vibrating lever, the upper and lower ends whereof carry the needle bar, which is connected to the aforesaid disc by a short connecting rod. This rocking lever is mounted on a fulcrum about midway of its length, and the effect of this arrangement is to cause reciprocating motion of the needle bar and needle fixed therein, and by the rocking or vibrating motion of the needle bar carrier produced by the action of the cam thereon and spring below to cause the needle to work the feed—a movement well known to sewing machine makers. As regards the looping motion, the improvement consists in causing the spindle employed to carry the thread round the bobbin to move in an universal joint or socket, so that the spindle does not rotate, but its extremities have a circular movement imparted thereto by a crank arm driven by the worm and worm wheel motion above described. The aforesaid crank arm is connected to one end of the aforesaid spindle, and the other end of the said spindle has a hook fixed therein for catching hold of the thread—a movement well known to sewing machine makers. This hook always remains upright, and in that position thus carries the thread round the bobbin. Last, as regards the tension of the sewing material from the bobbin, to prevent overrunning of the same, the patentee proposes to effect this by the following means:—At the upper part of the bobbin carrier he forms an opening, across which, and in a line with the sides of the bobbin, he passes a wire having a long hole in it, through which the sewing material from the bobbin is to be passed, and by turning this wire partly round so as to place the hole in the wire sloping, instead of upright, the edges of the hole will impede the free passage of the sewing material, and thus produce the required degree of tension; or the aforesaid wire may be turned entirely round when much tension is required.—Patent completed.

2531 J. J. HICKS. *Improvements in means or apparatus employed for lighting gas and other jets or lamps, candles, cigars, and other articles.* Dated September 7, 1867.

Here the inventor employs a tube closed at one end and open at the other. An opening is provided at any convenient part, through which the tube is supplied with any suitable liquid for burning; this opening may be closed in any suitable manner. In the open end of the tube or reservoir he places a cotton wick, which extends down into the tube or reservoir, the end of which may be curved or shaped to any suitable form. When the wick is lighted the apparatus is ready for use, and, if desired, will continue burning for a considerable period.—Patent abandoned.

2532 J. COCKSHOOT. *Improvements in the manufacture of carriages, coaches, and other vehicles.* Dated September 7, 1867.

This invention relates, first, to that portion of carriages, coaches, landaus, &c., called the "door framing," which has been hitherto made of wood, and secured together by wooden plugs or pegs. The improvements consist, first, in constructing the two upright pillars of the door frame (that is the hinge pillar and the latch pillar) of thin metal, and securing the other part of the frame and the panels (if necessary) thereto, and casting or forming the "male" part of the door hinge on such hinge pillar so as to constitute one piece, the hinge being constructed as in the specification of letters patent granted to the inventor, dated January 3, 1867 (No. 17). A second part of the invention relates to carriages wherein the door and window casing are in two parts, upper and lower, and the improvements consist in the application of a curved spring within the window space of the door, upon which spring the window falls when suddenly lowered.—Patent abandoned.

2533 J. SMITH. *Improvements in machinery for combing or dressing silk, flax, China-grass, cotton, or other fibrous substances.* Dated September 7, 1867.

This invention consists in the use of three or more endless card belts, or toothed or spiked endless aprons, placed and arranged side by side, and operated so that two adjoining surfaces of these belts are caused to travel in the same direction and parallel to each other. Also in the use of a series of travelling nippers or nipping jaws which are placed in a parallelogram of grooves, and caused to slide or travel in betwixt the said surfaces of the card belts, or toothed or spiked aprons, but to move in a contrary direction. Fibre being fed to these nippers intermittently in succession by ordinary feeding apparatus, they open and receive it, then close and move away from the feed apparatus detaching tufts of the fibre which they carry in betwixt the card belts or toothed or spiked aprons, the protruding ends being traversed in contact with the card, teeth, or spikes which comb or dress it; the jaws of the nippers are then opened, and the fibre is delivered on to a creeper or other receptacle.—Patent completed.

2534 J. B. ROGERS. *A projectile anchor and block for launching of the lifeboat and other boats in rough weather, and for ships' use in cases of loss of anchorage.* Dated September 7, 1867.

This apparatus consists of a trifluked hinged or folding anchor, so constructed that the shank can be so formed and so made that it can be fired from a mortar or other piece of ordnance. Attached to this anchor is a block of

Digitized by Google

a peculiar make for preventing its becoming choked in beds of sea weed, or such like obstructions, and to allow ropes of different sizes to pass freely, or wind kinks or knots that may occur in the transit; this block also has a swivel or swivels to allow for rotary motion. The connection of the block to the anchor can be either chain, hemp, rope, manilla rope, green hide, or other suitable appliances. A double line can be fired out by means of this block by being rove in the same, and can be fired from pin boxes or lines faked down.—Patent completed.

2535 J. Armstrong and E. Eccleston. *Improvements in steam engines.* Dated September 7, 1867.

This invention consists in certain arrangements of the parts of steam engines whereby the exhaust steam is compressed and re-introduced several times into the steam chest, until it is finally condensed by the usual surface condensers, by which method of using steam as a motive power great economy in fuel and boiler space is effected.—Patent abandoned.

2536 E. Hubner. *An improved rotary, steam, or gas engine, also applicable for pumping and measuring liquids.* Dated September 7, 1867.

Here the inventor makes use of a wheel of large diameter, in the circumference of which he makes a rectangular hollow groove turned on each face, within which he places a heavy semicircular metallic ring, adjusted to slide easily within the groove. This semicircular ring acts both as a piston and a cylinder bottom, and its object is to counterbalance by its weight the pressure of the steam introduced in the hollow groove. A certain number of sluices are adapted so as to intersect transversely the hollow part of the groove; they are put in motion by an eccentric loose on the shaft of the wheel, and maintained in the requisite position by a worm. The rods which unite the sluices to the eccentric are each provided with a piston working in a cylinder. The object of these pistons is to regulate the introduction of the steam, its expansion and its escapement.—Patent abandoned.

2537 D. Payne. *Improvements in priming machinery.* Dated September 7, 1867.

This invention is not described apart from the drawings. —Patent completed.

2538 J. and T. Bayley. *Improvements in the manufacture or production of leather.* Dated September 7, 1867.

Here the patentees obtain shavings of Russian leather, and when they have extracted the fragrance or perfume therefrom, they immerse the hides or skins in the extract or liquid, or other agent employed, containing the extract, in order to impart to the hides or skins the fragrance or perfume thus obtained; or they place the Russian leather in convenient layers between hides or skins, whether before or after the hides or skins are converted into leather, and the hides or skins are then placed in water, or other liquid or agent, where they remain any required period. They then apply oil or its equivalent agent to the hides or skins by rubbing them with it, or otherwise.—Patent completed.

2539 B. F. Stevens. *An improved illuminating roof and roof pavement.* (A communication.) Dated September 7, 1867.

This invention is not described apart from the drawings. —Patent completed.

2540 H. Woods. *Improvements in presses for extracting liquid from hops, seeds, and other substances.* Dated September 7, 1867.

Here the inventor inserts in the interior of the box, the centre by preference, a tube or chamber (of a conical or other form) perforated with holes, which tube or chamber communicates with the outside at either end, so that when the material in the press box is acted upon, the liquor or extract can be pressed out and escape, not only by the holes or apertures, or grooves in the box, or the casing of the box, but also by and through the tube or chamber formed or inserted in the interior of the box.—Patent abandoned.

2541 J. Whitham. *Improvements in machinery for puddling, and in puddling and other furnaces.* Dated September 7, 1867.

The patentee claims arranging puddling machinery substantially as described. He also claims mounting the jib or arm on which the bar or holder for the rabble or puddling tool swings on a hollow upright axis, supporting within it the axis with which the bar or holder is connected, and from which it receives its swinging motion. He also claims communicating a partial rotary motion to and fro to the jib or arm by means of a crank on an upright axis. He also claims the arrangement of arresting the motion of the jib or arm at either end of its course. He also claims constructing firebars, as described, with arms having slotted air passages in them, and so arranging such bars that the arms interlock, and so that the bars are capable of being rocked, all as described.—Patent completed.

2542 R. W. Ewer. *Improvements in winders suitable for folding or making up ribbon velvets for the market.* Dated September 7, 1867.

According to this invention, in place of winding or doubling the ribbon velvet on itself, the patentee employs winders with ends rounded, so as to avoid the production of sudden bends in the fabric, from which blemishes result. —Patent completed.

2543 C. Burn. *A new mode of propelling railway or other carriages.* Dated September 9, 1867.

This invention consists in the application of one or more friction wheels to the flanges of the railway carriage or other wheels, which friction wheel or wheels is or are pressed against and made to bite the flange of the carriage wheel by means of levers, weights, screws, eccentrics, or other mechanical contrivances, and when in contact with the carriage wheels the friction wheels are caused to revolve by manual power, thereby causing the wheels of the railway carriage to revolve, and by these means propelling the carriage.—Patent abandoned.

2544 E. J. C. Welch. *Apparatus for producing artificial ice, parts of such apparatus being also applicable to other purposes.* Dated September 9, 1867.

This invention mainly consists in the construction and arrangement of certain apparatus whereby ice can be artificially produced in an economical and simple manner, the refrigerating effects being produced by the evaporation of ether, or some other similar or analogous and suitable hydrocarbon, and the condensation of the resulting vapour.—Patent completed.

2545 A. Paul. *Improvements in stoppers or controllers for ships' cables.* Dated September 9, 1867.

This invention consists in constructing a stopper or controller for a ship's cable with a barrel, in contact with which the cable passes, which revolves with the cable, and to which frictional or other holding or controlling contrivances are applied, instead of gripping or compressing appliances being applied to the cable itself, as in ordinary stoppers.—Patent abandoned.

2546 W. E. Gedge. *Processes for extraction of the colouring matter of indigo from the waste textile fabrics which contain it.* (A communication.) Dated September 9, 1867.

Here the textile fabrics, or picked or torn waste, are filled in a vat having a false or double bottom, and there soaked with a solution of caustic soda at 1deg. Steam is then introduced at a pressure of three atmospheres, and after about five hours' boiling the liquid is drawn off charged with the whole of the colouring matter, which, precipitated from its solution by an acid, gives indigo as pure as the finest from India.—Patent abandoned.

2547 W. R. Lake. *An improved cartridge holder.* (A communication.) Dated September 9, 1867.

This invention is not described apart from the drawings. —Patent completed.

2548 C. E. Brooman. *A new process for producing hydrogen.* (A communication.) Dated September 9, 1867.

This invention consists in, and the patentee claims, the employment of the alkaline and alkaline terrous hydrates named, mixed in a chemically defined proportion, or without a determined proportion, with various mineral or vegetable combustible matters, in order to produce, at a red heat, in contact with these matters, hydrogen suitable for lighting and heating, and this in such apparatus of distillation and calefaction as it may be found convenient to employ, such as retorts, crucibles, and the like.—Patent completed.

2549 F. Tolhausen. *An improved process and apparatus for instantaneously disinfecting fecal and manuring matters, improving the same, and also rendering them fit for feeding domestic animals.* (A communication.) Dated September 9, 1867.

This invention relates to a process and apparatus for disinfecting instantaneously fecal and stercorous matter, and dejections of every description, by mixing or combining them as soon as produced with various disinfecting powders, consisting of mineral and vegetable substances The details of the invention are voluminous.—Patent completed.

2550 G. Clark. *Improvements in cartridges.* Dated September 9, 1867.

This invention consists in an improved mode of making cartridges, of which the principal feature is the application and use of paper or cloth chemically prepared, so as to ignite readily and burn rapidly without leaving a residuum, for the purpose of containing the gunpowder charge.—Patent abandoned.

2551 D. C. Brown. *Certain new and useful improvements having reference to wire heddles for loom harness, and particularly the construction, manufacture, and support of such.* (Partly a communication.) Dated September 9, 1867.

This invention is not described apart from the drawings. —Patent completed.

2552 J. Marsden. *Improvements in looms for weaving Scotch or ingrain carpets.* Dated September 9, 1867.

This invention consists, first, in obtaining a dwell to the batten during the throw of the shuttle by causing the crank to work in a curved slot formed in the connecting rod or arm, one end of the rod or arm being attached to the lathe sword, and the other end working in a socket or universal joint. Second, in a new combination and arrangement for working the shuttle boxes, and effecting the necessary changes required for throwing in the different coloured wefts. Third, in additional means for preventing damage to the shuttle when the latter fails to enter the box. The patentee cuts away that part of the lathe sword which usually projects above the shuttle race, and to which the hand-rail is ordinarily fixed. Fourth, the improvements relate to the picking motion, and consists in the use of what the patentee terms a double clutch box, working as described. Fifth, the improvements relate to a new form of "frog," which the patentee mounts so as to turn on a centre, and he attaches to an arm forming the lower part of the "frog" a spring which keeps it in proper position against a fixed stop; but when the shuttle does not act properly, and the "stop rod" consequently comes in with the "frog," it overcomes the action of the spring, and causes the lower arm of the frog to strike a little lever connected with the motion for stopping the loom, and, at the same time, another part of the frog coming in contact with the same fixed stop beforenamed, prevents the frog being driven too far back. Sixth, the improvements relate to an improved letting-off motion.—Patent completed.

2553 J. Eichharn. *Improvements in furnaces for melting iron and other metals, and for smelting ores.* (Partly a communication.) Dated September 9, 1867.

The patentee claims constructing furnaces for melting iron and other metals, and for smelting ores, in the manner described. He also claims constructing furnaces for melting iron and other metals, and for smelting ores, with an upright body or shaft carried on one, two, or other number of sides by arches or supports, underneath which in each case the fuel is able to issue from the shaft, and form a heap in an enlarged or outer chamber or hearth, to which air is admitted, and which air is then free to play over the whole of the upper surface of the ignited heap, and has, before it can ascend the shaft, to penetrate under the said arch or support of the shaft, as described. He also claims constructing furnaces for melting iron and other metals with two or more erect shafts combined with a common lower chamber or hearth, as described.—Patent completed.

2554 J. Turnock. *Improvements in cask stands.* Dated September 9, 1867.

The patentee claims constructing cask stands substantially as described. He also claims arranging the frame or cradle to tip on a centre, together with forming it with a projecting edge or parts at one end to assist in raising the cask, as described. He also claims locking the frame or cradle in position by a screw, pin, or bolt, passing through it, and through slotted openings in the side standards, and receiving a screw nut, as described.—Patent completed.

2555 J. Medhurst. *Improvements in fitting ships' rudders.* Dated September 9, 1867.

Here the patentee provides at the stern of the ship a rudder trunk of such a size that the rudder can be raised up on to the deck through it, and afterwards again lowered into its place; and in place of fixing the "braces" or the sockets which receive the pintels of the rudder to the sternpost, as is usual, he makes them capable of moving up and down a guide fixed in the sternpost. This guide he prefers to be a casting or forging fixed to the sternpost, and with a dovetail or undercut groove in it, and the braces are formed so as to fit into this guide, and be securely held by it. The pintels and braces are modified in form, so that they cannot escape the one from the other. He prefers to make them to form with each other ordinary hinge joints. When the rudder is in its place, the upper end of the trunk may receive a chock or filling piece; or a hinged port may be fitted at the bottom of the trunk and secured by a lashing, the top of the trunk being fitted with a hatch.—Patent completed.

2556 J. Jordan. *Improvements in the construction of stuffing boxes, slide valves, and steam jacketings.* Dated September 10, 1867.

This invention has for its object the construction of stuffing boxes, slide valves, and steam jacketings applicable to engines worked by the vapour of water, ether, methylated spirit, alcohol, or other suitable spirit vapour, and consists, first, in the use of two complete stuffing boxes having a chamber between them to receive any vapour which may escape from the cylinder through the inner stuffing box; the chamber is connected by pipes to suitable condensers or pumps, by which means the vapour is re-conveyed to the boiler or vaporizer and saved. The second part of the invention relates to an improved arrangement of slide valves, and consists in fitting four plain blocks of metal in suitable positions upon the cylinder, two at the top, and two at the bottom. The third part of the invention consists in surrounding the cylinder with two separate jackets or casings, forming two annular chambers around the cylinder, distinct from each other, and quite tight.—Patent abandoned.

2557 C. J. Spencer and F. Ware. *Improvements in steam boilers.* Dated September 10, 1867.

This boiler is of cylindrical form, and is similar in appearance to the ordinary vertical boiler, having an inside cylindrical firebox, at the bottom part of which are placed the firebars. Within this firebox is another cylinder closed at both ends, and suspended at a proper distance above the bars by horizontal flanged tubes of different sizes riveted to it and the firebox casing, thus forming passages in which the water circulates between the inner cylinder and the space enclosed by the firebox and the outer shell. Connecting the top plate of the inner cylinder and that of the firebox are smaller tubes, also for the passage of water and steam, and one or more large tubes are inserted between the top plate of the firebox and the top of the shell for the passage of flame and smoke. From the firebox top are also suspended tubes with their lower ends closed, dipping into the annular space between the firebox and inner cylinder. The flame plays on the outside of all the tubes while the water is contained within them. The form of the boiler obviates the necessity of staying except where the diameters are very large, and the tubes being all placed transversely to the direction of the flame, their heating surface is of the most efficient kind.—Patent abandoned.

2558 J. Dicken. *An improved yielding fish-plate employed upon railways.* Dated September 10, 1867.

This invention relates to that class of metal plates employed for securing the ends of rails on the permanent way of railways, termed "fish plates," and more particularly to those fish plates which are employed for joining the ends of the rails which form the points, and consists in the construction and arrangement of a yielding plate attached to the rails by bolts screwed perfectly tight, in contradistinction to an ordinary rigid or immovable fish plate, as now employed. For this purpose the inventor constructs a plate in two halves, joined vertically down its centre by a strong hinge or other equivalent. This joint is placed just at the point where the two ends of the rails to be joined meet, each half being firmly secured to its respective rail by bolts which, by preference, he forms with a conical hollow head provided with a split or opening which will allow, when tightened up, a greater latitude for expansion before becoming loose or ineffectual. The jointed plate when thus secured will allow the points to move with the greatest freedom, and at the same time obviate the constant attention of the platelayer.—Patent abandoned.

2559 J. H. Brown. *The production and manufacture of compressed leather, and articles of leather.* Dated September 10, 1867.

Here the patentee reduces shoemakers' shavings and the refuse cuttings of untanned hides to pulp, in a papermaker's engine, and adds thereto (say) 10 per cent. of untanned fibres to 100lb. of tanned leather fibres, and introduces about 4lb. of dissolved glue; he amalgamates them in a rag engine. He then takes wire moulds, and uses therewith woollen felt, and, by pressure, while the fibrous materials are in a soft plastic condition, forms them into sheets of the required thickness.—Patent completed.

2560 J. Holliday. *Improvements in fringes.* Dated September 10, 1867.

Fringes are often provided with ornamental tips, and other ornaments covered with silk and other material of costly manufacture, and sewn or stitched to the fringe. This invention consists in employing tips or other ornaments formed of wood, or other material, for the ends or other parts of fringes, gilt, or otherwise ornamented.— —Patent abandoned.

2561 C. E. Brooman. *An improved thermometer.* (A communication.) Dated September 10, 1867.

This invention consists in the construction of a metallic thermometer of great simplicity and economy of manufacture. It is based on the dilatation and contraction of a bi-metallic spring band according to variations of temperature.—Patent abandoned.

2562 J. Eichharn. *Improvements in steam boiler and other furnaces.* (A communication.) Dated September 10, 1867.

In constructing a furnace suitable for a steam boiler, a chamber is formed which is enclosed at the sides by the side walls of the boiler setting; at the top by an arch spanning the interval between the walls, and at the back the chamber is partly enclosed by a wall supported by another lower arch. At a short distance from and below the crown of this arch is the lower end of an inclined grid of firebars forming a partition in the chamber. The bottom of the chamber may be a cast-iron plate supported on the side walls, and the front is enclosed by doors; there is one door over the firebars for the introduction of fuel into the chamber, and another door opening into the space below the firebars, by means of which the air draft

Digitized by Google

through the bars may be regulated. The back of the chamber is open below the arch which supports the back wall, and the fuel descends out of it on to another or third arch or platform immediately beneath that just mentioned, and which forms a continuation of the bottom of the chamber. The fuel on this arch or platform is from time to time pushed back by the stoker, so as to cause it to fall over the back of the arch or platform on to the firebars beneath, on which a fire is thus maintained. It is supplied with air from an ashpit below the bars, which has a regulating door, and there is also a firedoor above the level of these firebars to admit of the workmen clearing the fire from time to time. The furnace is so regulated that a slow combustion is maintained in the fuel chamber whilst a bright and rapidly-burning fire is kept up on the bars below, and over this fire the smoke and products distilling from the fuel in the chamber have to pass, and so are effectually burnt.—Patent abandoned.

2563 C. SUTTON. *Improvements in optical apparatus designed to demonstrate the persistence of vision.* Dated September 10, 1867.

Here the inventor employs a metal frame with a suitable handle on which is mounted a toothed wheel and axis capable of being rotated by a crank; with the toothed wheel there gears a pinion, the axis of which is also carried by the frame, from which it projects so as to be able to receive upon it a number of suitably prepared models or forms, each of which is made with a socket to fit the end of the axis of the pinion. These models or forms, which may be very various, consist in each case of a strip of metal or other material bent to such a shape and so coloured that, when rapidly rotated (every point in the object describing a circle, which, in consequence of the rapidity of the motion, is visible to the eye), the illusion is obtained of a symmetrical solid of a circular section. According to the shape given to the model or form so the illusion will vary.—Patent abandoned.

2564 J. RAE. *Improvements in portable apparatus for cleansing and filtering water for army and other purposes.* Dated September 10, 1867.

This apparatus consists of a double cistern of metal carried on a suitable framing or cart body mounted on wheels for the purpose of transportation. The bottom of each half of the cistern inclines downwards, and has a central well or channel provided with a pipe or cock at the bottom for drawing off the sediment. The cistern is supplied with water from any source, such as from a pond, when on the march, for instance, either by a hand pump placed on the ground, or fixed at any point on the cart outside the cistern. In the well or bottom of the cistern the patentee places a filter open at top and bottom, and enclosed in a casing in such manner that the water entering from below will pass through the filter, and then into the casing with which delivery pipes extending at the back of the cistern are connected provided with taps for drawing off the cleansed and purified water. The cistern may be mounted on two or more wheels, and fitted with one or more filters.—Patent completed.

2565 J. WHITTOME. *Improvements in baling presses for pressing cotton and other substances.* Dated September 10, 1867.

The patentee claims the mode set forth of constructing and arranging the several parts of the apparatus for compressing cotton, and of applying the pressure of steam in combination with hydraulic pressure to compress cotton and other substances into bales for convenient transport. The down pressure is given to the follower for compressing the cotton, &c., by steam power, and the up pressure is given to the hydraulic follower by hydraulic power.—Patent completed.

2566 A. KINTON. *Improvements in the construction of water wheels.* Dated September 10, 1867.

Here the inventor proposes to construct the floats or boards of the wheel in such manner that they shall be capable of opening and closing in two sections, instead of forming, as hitherto, a fixed or constant float, the object being to free the ascending floats of the tail water.—Patent abandoned..

2567 J. POTTLE. *A new or improved cucumber box.* Dated September 10, 1867.

Here the patentee forms the box of glass, or wood and glass combined, or of glass, wood, and metal combined; the box is to be about 2ft. long and 2½in. wide, and the same in depth, interior measurement. The wooden sides and bottom of the box are to be made of deal about ¾in. thick, and feet may be attached to the base of the box to let it rest clear of the ground; or the box may be suspended by suitable supports, such as arches or standards, and pendants of wire or cord for the same purpose. The sides and floor or base of the box are to be secured or based together by zinc or other metal bands about ¼in wide. Grooves are cut on the interior of the sides of the box close to the top for a glass lid to slide within. This lid is to be formed in two parts, so as to be drawn out from each end of the box, meeting in the middle.—Patent completed.

2568 C. MATHER. *Improvements in machinery for washing ores, grain, wool, and other mineral, vegetable, and animal substances.* Dated September 11, 1867.

The patentee claims the application of a revolving cylinder, with internal screw or worm and buckets or lifters, and either with or without perforations at the discharging end, for washing ores and other substances, as described.—Patent completed.

2569 E. K. DUTTON and S. MASON. *Improvements in the bearings of hydro-extractors, and in the method of supplying lubricating matter to the same; applicable also to the lubricating of the bearings of other machinery.* Dated September 11, 1867.

These improvements in the bearings of hydro-extractors relate to the bearings in which the journals of the cage shaft run, and consist in forming the bearings of three or more blocks or pieces of hard wood suitably formed to be fitted into recesses formed in appropriate portions of the hydro-extractor, or its framing, the said blocks of wood being arranged at equal distances around the centre of the shaft, taper keys screwed at one end and fitted with nuts being employed to force the blocks nearer to the shaft as they wear. The bearing formed by the blocks of wood is preferably bored to fit the "journal," as is usual. In the case of an "upright bearing," an oil case or dipper of a circular form is fitted below the bearing in such a manner as to revolve with the shaft, and to "catch" the oil as it runs from the bearing, the circumference of the said oil case forming a circular channel in which the oil collects when the case is revolving. A stationary pipe or tube is fitted or formed at its lower end with a curved scoop having an open mouth, which is immersed or partially immersed in the oil, the upper end of the pipe being suitably formed to deliver the oil to the upper part of the bearing, the motion imparted to the oil causing it to enter the mouth of the curved pipe and to ascend the pipe until it runs over at the upper end of the pipe. The mouth of the pipe is curved in a direction contrary to the direction of the motion of the oil.—Patent abandoned.

2570 S. BROWN. *An improvement in the method of ornamenting bottles, vases, and jars used for perfume or toilet purposes.* Dated September 11, 1867.

Here the inventor combines for the purposes of ornament and utility a locket or case to contain a portrait or device with a perfume or toilet bottle, vase, or jar, and for that purpose he causes the bottle, vase, or jar to be made with a cavity in the side or stopper, and in this cavity he fixes by cement or otherwise a locket or case capable of being opened and closed, and of having a portrait or device inserted or withdrawn.—Patent abandoned.

2571 W. BAKER. *Improvements in the manufacture of iron, and in furnaces used in the manufacture of iron.* Dated September 11, 1867.

This invention relates to the puddling process, and the essence of the first part of the invention consists in melting the hammer slag or flux apart from the iron, and introducing the melted slag or flux into the bed of the pudding furnace in a melted state, and mixing it with the melted iron when the iron has ceased, or nearly ceased, to give off gas. The improvements in furnaces used in the manufacture of iron consist in forming a second or supplementary small bed in the furnace at the back of the flue bridge in which to melt the hammer slag or other flux used in the puddling process, and also in forming a passage in the flue bridge through which the melted hammer slag or flux may run to the bed of the furnace. The said passage may be temporarily closed by a plug of red iron ore.—Patent abandoned.

2572 A. M. CLARK. *Improvements in machinery for polishing, grinding, and edging slabs of marble, slate, and other minerals.* (A communication.) Dated September 11, 1867.

This invention is not described apart from the drawings. —Patent completed.

2573 W. BAIRD. *Improved apparatus to be used for registering the number of passengers entering vehicles.* Dated September 11, 1867.

At the entrance to the vehicle a movable step is placed constituting the lid or cover of the box wherein the registering mechanism is, by preference, contained, so that in entering the vehicle each passenger walks over or upon the movable step, the weight of the passenger causing the step to be depressed to an extent sufficient to actuate the registering mechanism. This mechanism comprises a ratchet wheel and pawl, teeth, index, &c., and springs for forcing up the lid of box in readiness for next registration.—Patent abandoned.

2574 F. WEINTRAUD. *Improvements in purses and other like articles.* (A communication.) Dated September 11, 1867.

This improved purse possesses the advantages of both a porte-monnaie and money bag. The inventor employs a purse frame, the halves of which are jointed to each other (at or near the bottom of the purse at the ends), and he leaves the joints free, that is to say, unattached to the leather or other material composing the body of the purse, so that, when the frame and purse are opened, the joints rise at the ends of the purse without raising the bottom of the purse, and therefore without diminishing its capacity, as is the case when the joints of the frame are secured to the bottom of the purse in the ordinary manner. The two sides of the purse are made in one piece of leather or other material passing under the bottom, and having the necessary fullness to give to the purse the desired capacity.—Patent abandoned.

2575 J. DAVIES. *Improvements in apparatus used in the manufacture of salt.* Dated September 11, 1867.

This invention consists, first, in applying mechanism to actuate rakes for raking the salt in salt pans of a rectangular form. The patentee attaches the rakes in rows to bars which reach across the pans from side to side, and the ends of these crossbars are attached to endless chains. There is one of these endless chains on each side of the pan, and they pass round suitably formed pulleys or chain wheels fixed on a shaft. An intermittent or continuous motion may be imparted to the shaft, and thence to the chains and rakes by ordinary mechanism. In the next place, the improvements consist in applying machinery for withdrawing the salt from raking pans of a rectangular form.—Patent completed.

2576 L. M PREWITT. *Improvements in stays, bodices, or corsets.* Dated September 11, 1867.

In the material of the stay openings are made in the front in a diagonal direction from shoulder to waist; these are to be drawn together or partially closed by the introduction of a piece of elastic webbing or cord; a gusset-shaped opening is made also in the back, extending only a short distance down from between the shoulders; this is also fitted with elastic web or cord. A pair of straps of elastic material, or fitted with elastic ends, are attached to the breast of the stays, and, passing over each shoulder, are crossed at the back, whence they are passed under the arms, and are secured to a stud in front upon the stay busk; another pair of similar straps or band is secured at the back, and by preference on the inside of the stay, passing through eyelets at the side, pass thence round the waist, and, meeting in front, are similarly secured upon a stud.—Patent abandoned.

2577 H. R. LUCKES. *The manufacture of artificial or compressed fuel in the treatment of coal, sawdust, and woody fibre, whereby those substances can be utilized when in a state of powder and converted into a serviceable fuel.* Dated September 11, 1867.

The object here is to produce bricks or blocks of fuel from small coal, &c. The cohesion of the divided particles of the carbonaceous substance employed is effected by incorporating with them a mucilage obtained by boiling or otherwise from the common descriptions of seaweed.—Patent abandoned.

2578 W. E. NEWTON. *Improvements in anvils.* (A communication.) Dated September 11, 1867.

This invention is not described apart from the drawings. —Patent completed.

2579 W. E. NEWTON. *Improvements in saws.* (A communication.) Dated September 11, 1867.

The patentee claims, first, perforating saw blades with a number of holes in rear of the teeth, as set forth, for the purpose of admitting of the lengthening of the teeth when the latter are worn away by use, without the process of "gumming" or re-cutting the throats or spaces between the teeth. Second, the use of male and female dies constructed and arranged, as shown and described, for the purpose of cutting out the teeth or the throats, or spaces between the same, and also the holes in rear of the teeth, at one operation, and admitting of the adjustment of the parts which cut out these holes in such a manner that the latter may be cut or punched in straight or curved lines, as may be required. Third, securing the handle sockets to the saw blade by rectangular slots in the ends of the saw blade, and the screw bolts provided with the taper portion, as set forth.—Patent completed.

2581 J. B. MELDRUM. *Improvements in printing textile fabrics.* Dated September 12, 1867.

The patentee claims the application of aniline dyes for printing of jute fabrics, or fabrics in which jute is a component part, for the purpose of rendering the appearances produced more brilliant and durable than hitherto.—Patent completed.

PROVISIONAL PROTECTIONS.

Dated November 22, 1867.

3313 J. H. Brown, Exeter Hotel, Strand. A new game, to be played with balls and cues or other media for propelling the said balls, and also for the peculiar construction of the table on which the same is played, together with the several mechanical appliances and figures.

Dated January 1, 1868.

1 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in apparatus for regulating the speed of steam and other engines, and for indicating the power of the same. (A communication.)

Dated January 18, 1868.

180 H. A. Bonneville, Sackville-street, Piccadilly. Improvements in ribbon looms. (A communication.)

Dated February 12, 1868.

482 J. Towle, Cold Harbour, near Oxford, Berkshire, justice of the peace. Improvements in the arrangement of sewers and drains for the collection and distribution of sewage matters.

Dated March 2, 1868.

709 F. Neiber, Vienna, Austria, manufacturer. Improvements in fastenings for glove boxes, cigar cases, necessaires, and other articles.

Dated March 3, 1867.

718 J. Barker, Todmorden, Yorkshire. Certain improvements in the method of consuming smoke from the fuel used in furnaces, and in the method of supplying fuel to furnaces, and in apparatus connected therewith.

Dated March 4, 1868.

747 G. Davies, Serle-street, Lincoln's Inn. Improvements in the manufacture of gas for lighting and heating. (A communication.)

754 A. V. Newton, Chancery-lane. Improved apparatus for measuring spirituous liquors. (A communication.)

Dated March 5, 1868.

760 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in mechanism for preparing soles, and for sewing the same upon boots and shoes. (A communication.)

Dated March 6, 1867.

777 J. Eastwood, Blackburn, Lancashire, machine maker. Improvements in machinery for preparing size, and in machinery or apparatus to be employed in the sizing of yarn and other fibrous materials and fabrics.

783 T. Atkins, Fleet-street, City, engineer. Improvements in feeding bottles for infants and invalids.

785 J. Houston, jun., Glasgow, soap and candle manufacturer. Improvements in the manufacture of composite candles, and in the machinery or apparatus employed therein.

Dated March 7, 1868.

787 H. Hargreaves, Barnley, Lancashire. Certain improvements in looms for weaving.

791 H. Symons, Kentish Town, hardware manufacturer. Improvements in fireguards and firescreens.

793 C. E. Brooman, Fleet-street, City, patent agent. Improvements in combing machinery. (A communication.)

795 W. Berry, Bradford, Yorkshire, machine makers. Improvements in foot-steps for upright spindles and shafts.

797 R. M. Chevalier, Beresford-terrace, Notting Hill, W., civil engineer. An improvement in the manufacture of the blinds usually called Venetian blinds.

799 W. H. Warner, Ross, Herefordshire, and R. C. Murray, Jermyn-street, Middlesex. Improvements in stereoscopes.

801 F. J. Baynes, Holloway-terrace, Holloway-road, Islington. Improvements in kitchen ranges and parts connected therewith, which improvements are also applicable to other cooking stoves.

803 P. Koch, New Haven, Connecticut, U.S., machinist. Machinery for making metallic nuts.

Dated March 9, 1868.

805 J. Jeavons, Sheffield, iron maker. Improvements in the manufacture of tyres for railway and other wheels.

806 W. Hartley, Heywood, Lancashire, cotton spinner. A machine for preparing and conditioning yarn.

809 L. Blumfeld, Wood-street, Cheapside, City. Improvements in the construction of cigar tubes and pipes, when used in combination. (A communication.)

811 W. Piddin?, Brunswick-square, Middlesex. Improvements in pockets formed in gloves, and in the mode of securing railway tickets, money, or other contents deposited therein for safe keeping.

813 P. W. Barlow, Blackheath, Kent. Improvements in machinery for constructing tunnels.

815 W. H. Halsey, Hoboken, New Jersey, U.S., manufacturing jeweller. A new and improved process for making articles from hard rubber, and from other substances capable of being moulded in dies, and at the same time inlaying and attaching to such articles metallic plates for ornamental purposes.

817 P. F. Halbard, Burton-on-Trent, Staffordshire. Improvements in stench traps.

Dated March 10, 1868.

819 J. Slater, Catherine-terrace, Lansdowne-road, S.W., Surrey, engineer. Improvements in heating the feed water for steam engine and other boilers, to economize the consumption of fuel and feed water, and in apparatus therefor.

Digitized by Google

820 W. B. Kinsey, Cannon-street, City, engineer. Improvements in apparatus for carburetting or increasing the illuminating properties of coal gas.

821 C. D. Abel, Southampton-buildings, Chancery-lane. Improvements in the production of brown colouring matters for dyeing and printing. (A communication.)

822 S. Desborough, Staining-lane, City. Improvements in apparatus for cleaning and polishing knives, forks, and other articles.

823 J. Jones, Durham. Improvements in finishing, straightening, and punching rolled, railway, and other bars of iron and steel.

824 R. Meldrum, Pittormie, Cupar, Fifeshire. Improvements in apparatus for raising water.

825 J. G. Douglas, Cork, engineer. Improvements in valve motions for oscillating cylinder engines.

827 A. Bourdon, Boulevard du Prince Eugene, Paris, engineer. Improvements in looms for weaving.

828 A. V. Newton, Chancery-lane. Improved apparatus for lubricating machinery. (A communication.)

829 J. Wallis, Greenwich, Kent, miller. An improved mode of, and apparatus for, dressing millstones.

830 C. Attwood, Wolsingham, Durham, iron master. Improvements in the production or manufacture of steel and iron of a steely character.

831 H. E. Smith, Herefordshire, engineer. Improvements in steam engines and boilers.

Dated March 11, 1868.

833 S. Brooks, Union Works, West Gorton, Manchester, machine maker. Improvements in machinery for preparing, spinning, and doubling cotton and other fibrous substances.

834 E. and J. Broadbent, Manchester, paper manufacturers. Improvements in machinery for manufacturing paper bags.

835 F. Winser, Manchester, and I. Swindells, Kegworth, Leicestershire. Improvements in the utilization of the waste products arising from esparto grass and other fibrous materials used in the manufacture of paper and other purposes.

836 F. Winser, Manchester, and I. Swindells, Kegworth, Leicestershire. Improvements in the manufacture of sulphate of magnesia.

837 B. Browne, King William-street, City. Improvements in the construction of girders or rails, railway chairs, sleepers, switches, points, and crossings, and in the mode of laying, fixing, and working the same on lines of railways, and in other situations. (A communication.)

838 T. Walker, Robert-street, Chelsea, engineer. Improvements in the construction of electric telegraph cables and lines, and in the mode of, and apparatus for, or connected with the transmission of electric currents.

839 S. Naylor, Ravensfleet, East Stockwith, Lincolnshire, engineer. Improvements in apparatus for raising water.

840 M. T. Shaw and T. H. Head, Cannon-street, City. Improvements in rolling iron and steel, and in wrought girders and joists, and in machinery for producing the same.

842 W. Hawthorn, Newcastle-upon-Tyne, engineer. Improvements in steam generators and other boilers.

Dated March 12, 1868.

843 F. A. Paget, Seymour Chambers, York Buildings, Adelphi, Strand, civil engineer. Improvements in constructing ships' compasses and their binnacles, and in preventing the deviations of compasses in iron or steel ships.

845 F. Ryland, West Bromwich, Staffordshire, mechanical engineer. Improvements in the manufacture of pulleys for suspending window frames, and for other like purposes.

846 W. Thompson, Rathbone-street, Canning Town, Barking-road, Essex. Improvements in the manufacture of iron castings.

847 H. Fletcher, Old Hall-street, Liverpool. An improved method of obtaining and applying motive power.

848 W. A. Lyttle, of the General Post Office, London. Improvements in the means and apparatus for supplying boilers with water.

850 T. Barnes, How Gill, near Gisburne, Yorkshire, cotton waste spinner and manufacturer. An improved method of, and machinery for, preparing rovings from waste and other inferior fibrous materials.

851 A. P. Stephens, Brooklyn, New York. Improvements in vises and similar clamping mechanism.

852 J. Hodgeson, Latchford, Chester, railway signal fitter. Improvements in railway and other signals, and in mechanism for actuating the same.

853 W. E. Newton, Chancery-lane. Improvements in ballasting vessels. (A communication.)

854 A. and E. Geary, Horsfield-road, Bristol, ironmongers. Improvements in cinder sifters.

855 B. Britten, Red Hill, Surrey. Improvements in the manufacture of manure.

Dated March 13, 1868.

858 S. Bates, lace manufacturer, and W. Redgate, draughtsman, Nottinghamshire. Improvements in the manufacture of lace in twist-lace machines.

860 G. F. Lyndon, Birmingham, manufacturer. Improvements in rotating shafts and axles and their bearings, and in the means of lubricating the same.

861 M. Rowand, Lewisham, Kent. Improvements in the treatment or preparation of the ingredients employed in the manufacture of fermented liquors.

862 W. M'Naught, Rochdale, Lancashire, engineer. Improvements in steam engines, steam boiler and other furnaces, and in apparatus for heating the feed water.

863 C. S. Moller, Philpot-lane, City. An improved portable side weapon adapted for the use of the army more particularly. (A communication.)

864 H. Kershaw, Laister Dyke, Yorkshire. Improvements in apparatus employed in spinning worsted and other fibres.

866 S. H. Salon, Regent-street, optician, and T. Field, Vine-street, Westminster, machinist. An improved apparatus or instrument for clipping the hair of horses and other animals.

Dated March 14, 1868.

868 W. G. Beattie, South Bank, Surbiton, Surrey, engineer. Improvements in steam pistons.

869 S. Holness, Ufton-grove, Southgate-road, Kingsland. Improvements in, or additions to, speaking tubes for intercommunication in railway trains and buildings.

871 W. Bellhouse, jun., cotton spinner, and R. Ashworth, mechanic, Manchester. Certain improvements in carding engines.

872 J. B. Handyside, Glasgow, engineer. Improvements in apparatus for applying springs to railway rolling stock and otherwise.

873 J. P. Knight, New Cross, Kent. A new or improved indicator lamp and semaphore for cabs and other public carriages, and for floating vessels, also for regulating the traffic in the public thoroughfares and rifle practice.

875 F. Mulliner, Northamptonshire, carriage builder. Improved apparatus to be used in connection with the poles and splinter bars of carriages.

876 J. Clay, Yardley, Worcestershire, saddler. Improvements in harness, saddles, and harness pads.

877 J. Carter, Birmingham, boat builder. Improvements in machinery for the manufacture of nails and spikes.

878 W. A. Lyttle, of the General Post Office, London. Improvements in apparatus for closing and securing boxes, bags, and other packages.

879 P. F. Gubault, shoemaker, Rue Milton, Angers, France. Improvements in machinery for finishing boots and shoes.

Dated March 16, 1868.

880 J. Norman, Glasgow, engineer. Improvements in apparatus for dressing millstones.

881 E. V. de Forville, Prairie au Duc, Nantes, department of the Loire Inferieure, France, merchant. An improved machine for crushing and sifting flour.

882 F. A. Baumann, Heilbronn, Wurtemberg, civil engineer. Improvements in the construction of rotary engines.

883 T. S. L. Beech, Charlton, Kent. Improvements in engines for obtaining rotary motion by means of steam, water, gas, or other fluids.

884 H. F. Griffiths, mechanical engineer, and A. Beard, jun., manager of works, Wolverhampton. Improvements in apparatus for puddling iron and steel.

885 W. Arthur, Upper Kennington-green, Surrey, and W. Arthur, Albany-street, Regent's Park. The support and cure of hernia by means of a new and improved form of truss.

888 H. A. Bonneville, Sackville-street, Piccadilly. New and improved apparatus for manufacturing cartridges. (A communication.)

890 D. Greig, Leeds. Improvements in traction engines and other engines to travel on common roads.

891 W. E. Newton, Chancery-lane. Improvements in the manufacture of illuminating gas in the distillation of hydrocarbons. (A communication.)

892 W. E. Newton, Chancery-lane. Improvements in telegraphic apparatus. (A communication.)

894 J. H. Johnson, Lincoln's Inn-fields. Improvements in the manufacture of wheels for vehicles, and in the machinery or apparatus employed therein. (A communication.)

895 P. J. Livsey, Manchester. Improvements in machinery for combing cotton and other fibrous materials. (A communication.)

896 J. S. Gee, Gloucestershire. Improvements in ornamenting slate and such like materials to be afterwards enamelled.

Dated March 17, 1868.

897 R. Sims, Bedford Leigh, Lancashire, agricultural implement maker. Certain improvements in horse rakes.

899 W. Hulse and E. Williams, Birmingham, manufacturers. Improvements in the manufacture of metallic bedsteads and other articles of metallic furniture.

901 W. E. Gedge, Wellington-street, Strand. Improved fuel. (A communication.)

PATENTS APPLIED FOR WITH COMPLETE SPECIFICATIONS.

Dated March 19, 1868.

930 C. E. Green, Blandford-street, Portman-square, and J. Green, Windermere Cottage, Winchmore Hill, Edmonton. Improvements in the manufacture of cartridges for breech-loading firearms.

944 H. F. Shaw, West Roxbury, Norfolk, U.S. Improvements in machines for overcoming resistance.

Dated March 23, 1868.

970 V. A. Deaubeuf, Maindy, Cardiff. Improvements in machinery for the manufacture of compressed fuel from small coal and other material.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the "London Gazette," March 31, 1868.

3265 E. T. Hughes. Knitting machines. (A communication.)

3266 W., J., and J. Busfield. Preparing slivers of wool for spinning.

3267 W. J. Hanson and J. C. Ellison. Method of dyeing textile fabrics.

3270 G. Fitt. Artificial manure.

3281 C. Mole. Manufacturing soles and heels for boots and shoes.

3286 J. Oppenheimer. Telegraph posts.

3287 H. Greene. Safety lamp.

3288 Baroness C. de Lavenant. Coating metals.

3293 W. R. Lake. Packing for the piston heads of steam cylinders. (A communication.)

3300 W. Blundell. Cowls for chimneys.

3310 T. G. F. Dolby. Apparatus for warming solid and liquid food.

3316 G. H. and E. Bolton, W. Whitthead, and T. Robinson. Obtaining motive power.

3318 P. Salmon. Manufacture of gas.

3320 W. Macnab. Marine steam engines.

3321 C. E. Brooman. Steam generators. (A communication.)

3324 J. H. Johnson. Breech-loading firearms. (A communication.)

3326 T. Barton. Cribbage board.

3327 F. Brown. Kitchen ranges.

3328 G. Turner. Packing cases.

3332 R. Ward. Machinery for spinning tobacco.

3333 T. Chalmers. Machinery for producing seamless tubes. (A communication.)

3334 A. V. Newton. Rotary steam engines. (A communication.)

3337 W. Sim. Apparatus for watering streets.

3342 C. E. Penny. Envelopes.

3356 W. Fowler and J. Griffiths. Tyres of railway wheels.

3380 J. R. Pratt. Construction of articles of earthenware.

3383 J. R. Towers. Bedsteads.

3387 J. Fraser and G. Duncan. Machinery for printing.

3394 A. Turner and W. E. Newton. Carpets.

3396 A. M. Clark. Chronometers. (A communication.)

3402 W. Starkey. Obtaining motive power.

3414 G. Heiron. Castors for containing pepper and salt.

3443 N. Grew. Apparatus for cleaning cotton.

3445 C. Paley. Elastic material.

3495 E. Keirby. Elastic packings.

3517 A. M. Clark. Process for the reduction of tin. (A communication.)

3559 J. Hargreaves. Manufacturing soda.

3589 F. L. and C. L. Hancock. Propellers.

3604 H. H. Murdock. Apparatus for propelling canal boats. (A communication.)

3610 J. Atkins. Metallic bedsteads.

3611 J. Clay. Saddles.

3613 E. Breffit. Glass bottle house pot carriages.

3622 G. Davies. Knitting machines. (A communication.)

3636 E. and A. Ludlow. Machinery for the manufacture of cartridge cases.

3710 G. M'Culloch. Thread-polishing machines.

1 W. R. Lake. Apparatus for regulating the speed of steam engines. (A communication.)

141 T. Travis, W. H. Prince, and J. Tomlinson. Machinery for clearing yarn.

489 C. Blyth. Machinery for measuring cloth for bags.

519 A. H. Brandon. Breech-loading firearms. (A communication.)

609 J. Macintosh and W. Boggett. Manufacture of elastic goods.

731 T. Johnson. Treating ores.

759 W. Hunt. Treating certain compounds of copper and iron.

830 C. Attwood. Manufacturing steel and iron.

880 J. Norman. Dressing millstones.

886 H. A. Bonneville. Jacquart looms. (A communication.)

891 W. E. Newton. Manufacture of gas. (A communication.)

930 C. E. and J. Green. Cartridges.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list, who have given notice of their intention to proceed, within twenty-one days from the date of the "Gazette" in which the notice appears, by leaving at the Commissioners' office, particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed March 27, 1868.

2744 M. Hamer
2751 W. James and W. Hill
2752 J. Donald
2765 R. Fletcher
2778 H. Haschke
2787 G. Townsend
2794 J. Gutmann
2848 T. Blacknurst
2807 A. Bradburn and S. T. Marsh
2904 W. E. Newton
2924 H. Sharp and F. W. Webb
278 G. Kellogg
442 W. R. Lake
443 W. R. Lake

Sealed March 31, 1868.

2759 J. G. Jones
2760 G. Allibon and A. Manbre
2766 T. E. Clarke
2767 W. and S. Smith
2768 R. H. Taunton
2769 F. Parkes
2773 J. H. Nelson and T. Briggs
2776 F. J. Jeffery
2777 C. Mace
2780 W. Spence
2789 A. T. Becks
2801 J. Anderson
2810 J. Piddington
2820 H. Trotter
2821 T. Ollis
2834 R. Reid and E. H. Craigie
2839 J. James and T. Jones
2845 W. Warren
2870 R. F. Bare and J Thomson
2877 J. H. Johnson
2901 F. D. Frost
2910 E. Shaw
2942 A. F. Jalourcau and C. L. Lardy
3019 F. M. Smith
3042 E. B. Wilson
3091 T. B. Cutts and F. W. Brooksbank
3107 W. E. Newton
3138 C. L. Hett
3469 P. G. L. G. Designolle and J. Casthelaz
3501 H. Bessemer
98 J. G. Tongue
109 J. G. Tongue
150 W. Betts
376 J. Dewar

PATENTS ON WHICH THE STAMP DUTY OF £50 HAS BEEN PAID.

828 W. Simons and A. Brown
844 H. C. Hurry
850 J. Dodd
856 J. Todd
863 J. Bruckshaw and W. S. Underhill
864 F. Le Roy
876 F. A. Mocquard
882 J. Wright
884 W. Irlam
898 W. Savory
900 A. A. Croll
923 R. A. Brooman
945 J. R. Wigham
996 W., E., and J. Gray
1004 A. Homfray
1043 J. Walker
1344 R. and H. Harrild

PATENTS ON WHICH THE STAMP DUTY OF £100 HAS BEEN PAID.

759 T. Davison and R. Paterson
778 W. Sorrell
788 W. D. Napier
795 R. Ridley and J. Rothery

THE

MECHANICS' MAGAZINE.

LONDON: THURSDAY, APRIL 9, 1868.

LONG *VERSUS* SHORT SPAN BRIDGES.

THE introduction of railways, it must be admitted, imparted a stimulus to engineering sufficient to raise it to the dignity of a profession, a position it can hardly be correctly stated to have previously attained. With the practical development of the new system of locomotion arose the most extravagant ideas respecting its ultimate destiny. An unparalleled velocity of transit was implicitly believed in, and confidently relied upon. Bridges of surpassing dimensions were considered merely subsidiary adjuncts to the construction of a line, and an arm of the sea, or a chain of mountains, was regarded as a troublesome but a very trifling difficulty. How have these expectations been answered? how have these ideas been realized? It is true that something has been done, something effected, but how little in comparison with what was anticipated. We have crossed the Straits of Menai a second time, we are more than half way through the Alps, and we have pierced the Isthmus of Suez. But we have not connected England and the Continent; the sea still rolls, unspanned, between Europe and Asia, and an inland route to our vast Indian possessions is as much a question of the future as when the subject of the Euphrates Railway was first thrust upon the notice of the Government and public. In our present article we propose to direct attention to the complete change of opinion that has taken place with regard to bridges possessing very long spans. So soon as the employment of wrought iron demonstrated the advantages it possessed over the older materials used for constructive purposes, it was imagined by some that all our rivers, over which it was necessary to carry a bridge, would be crossed, not by successive leaps but at a single bound. It is well known now that some of the few railway bridges really existing as examples of a long span could have been built in a more economical manner had a different principle been adopted.

Disregarding the somewhat treacherous nature of the material, the limits of cast-iron girders, especially for railway purposes, are soon reached. The arch may be perhaps considered an exception to this rule, particularly when we have before us the instance of that at Southwark Bridge, the centre span of which equals 240ft. It must, however, be borne in mind that this bridge is only used for road traffic, although the real objection to the general employment of the arch form upon a large scale is the impossibility of affording a sufficient amount of rise to enable a curve to be obtained endowed with the property of correct equilibration. The failure of the horizontal cast-iron girders, or rather that of what may be appropriately termed the compound cast-iron girder, constructed of cast-iron beams trussed with wrought-iron rods, demonstrated that even for moderate spans, when intended for steam traffic, this principle was inadequate to fulfil the conditions of strength and safety, conditions which were speedily stringently insisted upon by the Board of Trade in the interest of the public. To wrought iron, therefore, engineers began to look for the accomplishment of their stupendous designs; but, curiously enough, the arch was abandoned at the very introduction of the new material, it being impracticable in railway bridges to employ that form generally. The centre spans of the new Blackfriars Bridge, which are 185ft. across, will, we believe, be the representative of the largest example of a wrought-iron arch. Those of the Victoria Bridge over the Thames do not exceed 175ft. in the clear. The horizontal girder appeared to offer, more especially in the matter of headway, considerable advantages over the arch form, and consequently the first specimens were instances of that principle. It was this latter consideration that determined its application to the crossing of the Menai Straits, which contains at present the longest single span of any railway bridge in the world. The centre spans of Brunel's stupendous erection at Saltash fall short of its dimensions by several feet, and the subsequent structures in America and our own country do not approach it in magnitude. The question has frequently been asked, are bridges of enormous span, engines of extraordinary weight, ships of gigantic proportions, and guns of unparalleled dimensions, costly blunders? Were we to regard the matter solely in one point of view, we fear the answer would be in the affirmative; and with the facts before us it is difficult to arrive at any other conclusion. The broad gauge, the design of one of the greatest engineers that ever lived; the "Great Eastern," the offspring of the same master mind, have both proved failures; the weight of our present engines, and the enormous disproportion it bears to the mass set in motion, is not dictated by design or economy, but is simply the result of an unscientific necessity. So with our bridges. That over the Menai Straits has never been equalled, much less eclipsed, and there is no question but that the multi-span principle has proved itself in point of economy superior to the system of crossing an intervening space in one gigantic leap.

The first engineer who laid down this principle, and adhered to it most rigidly in practice, was Colonel Kennedy, the engineer to the Bombay, Baroda, and Central India Railway. Throughout the whole of this line, with one or two solitary exceptions, which were occasioned by the nature of the river bed, a uniform span of 60ft. has been adopted, and the construction of the bridges is that of a wrought iron Warren girder supported upon cast-iron screw piles. The destination of the girders, and the difficulties attending their erection, had, no doubt, some influence upon the selection of the method put into practice, but at the same time the whole principle was submitted to a thorough investigation before the system of short spans *v.* long ones was finally decided upon. The whole question rests upon the relative economy of piers balanced against superstructure; but there is this point to be noticed which bears somewhat favourably upon the long span system, that the cost of sinking a pier, or even a number of piles, is always an unknown quantity, whereas the erection of the superstructure can be estimated to a few pounds. It is rarely the latter item that delays the progress of a structure, but the former is a common source of vexation and expense, whenever the foundations have to be got in under water. So far as the modern arched bridges across the Thames are concerned, the multiplicity of spans into which they are divided does not enter into the comparison, since the exigencies of the over traffic do not now permit of anything beyond the minimum rise. But the adoption of small spans for the three new railway bridges is an indisputable testimony to the superior economy of that principle. In the case of the Charing Cross structure, it might have been supposed *primâ facie*, that as there were a couple of existing piers and abutments which merely required widening, nothing would have been simpler than to have utilized them at once, and replaced the old suspension bridge by another having the same spans, and differing only in form and dimensions. It is true that the centre span would have exceeded in length that of any other existing similar structure, but still there was the Britannia Bridge as a precedent, and it would be a great injustice to our engineers to suppose that any insurmountable difficulty would have been experienced upon that point. The argument that tells most strongly against the long or single span principle is that the cost of constructing a girder increases in a far higher ratio than that of the mere augmentation of its span. With piers it is different, for, *cæteris paribus*, the cost of any number of piers in the same situation will, upon the average, be in simple arithmetical progression. Occasionally there are departures from this law, as in the foundations of the piers for the new Blackfriars Bridge. It has been necessary in one case to sink the caissons nearly 20ft. below the ordinary depth; but this is quite an exceptional occurrence. The London, Chatham, and Dover Railway Bridge over the Thames is another example of the employment of the short span principle, and it may be fairly concluded that in England, at all events, we shall not witness many future rivals to erections so magnificent as the Britannia and the Royal Albert Viaducts. Across an impassable gorge, a precipitous ravine, or a furious torrent, it may be impossible to employ any other than a bridge of single span, and the importance attached to the connection of the opposite sides must determine whether the necessary outlay is justifiable or otherwise. For the future, it may be asserted, judging from the data we have adduced, that short spans will be the rule, long ones the exception.

MAGNETIC PHANTOMS.

A CONTEMPORARY gives a very learned account of the magnetic figures produced in iron filings, in the following words:—"Magnetic phantoms produced by sprinkling iron filings on a sheet of paper laid on the poles of an electro-magnet, have for some years past been regarded as curiosities, and made the subject of popular demonstration. But it is now known that they have a scientific value, inasmuch as they indicate the condition of the magnet; whether, for instance, the poles are isonomal or antinomal, isodynamic or hetrodynamic, with points consequent or not, or bifurcated, trifurcated, circular, and so forth . . . ." These are *prave orto*, and, it may be, do stand for something; but we are obliged to confess "we don't see it." Although we have made many hundreds of experiments both with electro-magnets and permanent magnets, and iron filing figures, still we never met with anything in electro-magnets that we could apply such names to. We take it to be quite easy to make an electro-magnet that shall have apparently isonomal poles; but we should like to say poles of the same name, that is, having two external N. or two external S. poles. Still we hold it to be impossible that any magnet can exist with two poles of the same name, whether it be electro or permanent, any more than a walking-stick can be imagined with only one end.

Now, if the coil on an electro-magnet be divided into two portions, and the current of electricity be sent through these halves in opposite directions, or if one half be a right hand coil and the other a left hand coil, and the current be sent through them in the same direction, then there will be exhibited at the external ends poles of the same name; but this is not an electro-magnet with poles of the same name, but really two electro magnets, one for each half coil, and it is possible to make an iron bar into as many separate and distinct magnets as reversed coils can be put upon it; but it is not possible to make one magnet with poles of the same name; therefore, iron filings cannot show it, and it is a wonder to us how anyone knowing anything of the matter can imagine such a thing. So much for isonomal and antinomal. Then

Digitized by Google

come isodynamic and hetrodynamic. One is at a loss to know what the writer means to convey by these terms as applied to magnetism. Magnetism is a static force as exhibited by a magnet, there being motion in the magnetic sphere of the magnet only on the instant of making or unmaking of the magnet, or in the increasing or diminishing of its sphere by means of the connecting or unconnecting of its poles, or otherwise; but a magnet once made can exist in a perfectly static state. If this dynamic state of becoming a magnet is meant, then what nonsense to talk of iso- and hetro-dynamic power in a magnet. The motion must be in one direction, for X — X = 0; therefore, no dynamics at all.

Then, as to the consequent and inconsequent points, what are we to make of these? Really, we are at a loss; however, this point is of no consequence. But the bifurcated, trifurcated, polifurcated, and circular points, they are quite away in the clouds beyond mathematics and human reason, or, at least, our poor human reason. Clearing away all this beautiful second-hand scientific language there is something under it. These iron filing magnetic figures are, and, as we believe, have always been, of scientific use. For example, in magnetizing steel bars for permanent magnets, in what other way are we to detect faulty bars. Though the steel may be selected with the greatest care, and very carefully hardened and tempered, and they may appear to be perfectly similar, yet on being magnetized it is probable that not more than 30 per cent. will be good; at least, we have always found it so. If the fault be in defective tempering that is easily rectified, but if it be through internal flaws, iron filings only will detect these. Let the bar be magnetized and covered with a stout sheet of paper on to which sift iron filings, and if they arrange themselves round several vacant points along the bar it may be concluded that under these there is an internal flaw, and in all cases it will be found to be so on breaking the bar: such a bar is of no use for a magnet. The cracks in the bar divide it into a series of small magnets.

This is the use that these figures have been put to for many years—at least, we have used them for this purpose, and no doubt others have done the same; but latterly the principle has been put to a most valuable use in a manufacturing and engineering point of view. It has been applied to testing the soundness of manufactured iron, for the detection of internal flaws and unsound welds. For the testing of chain cables and anchors it will be invaluable, so much property and so many lives depending on their soundness. Though these may look sound and perfect externally, they may have internal flaws which will surely cause them to give way when the stress comes upon them. For testing chains and anchors experimentally, it has already been applied, and doubtless it will be soon brought into universal practice, and also for testing the material of which bridges are to be made, and also railway wheels and tyres, and, in fact, manufactured iron of every kind which is required to resist great strains or shocks.

TECHNICAL EDUCATION. — MR. WHITWORTH'S BENEFACTION.

A VERY important and highly praiseworthy and practical step has just been taken by Mr. Whitworth to further the object of scientific education. While so many have been talking, that gentleman has been doing, and has set an example well worthy of imitation by those large employers of skilled labour whose interests will be so directly and materially served by the improved education of their men. On the 18th of last month Mr. Whitworth wrote to the First Lord of the Treasury offering to found thirty scholarships of the annual value of £100 each, to be applied for the further instruction of young men, natives of the United Kingdom, selected by open competition for their intelligence and proficiency in the theory and practice of mechanics and its cognate sciences, with a view to the promotion of engineering and mechanical industry in this country. Mr. Whitworth proposes that these scholarships should be tenable on conditions to be defined by a deed of trust regulating the administration of the endowment fund during his life, and that thereafter the management of this fund, subject to the conditions specified therein, should rest in the Lord President of the Council or other Minister of Public Instruction for the time being. We have not yet the details of the exact way in which Mr. Whitworth wishes his intention to be carried out; this, of course, will be made known after a while. In the mean time, however, let those who are in a position to follow Mr. Whitworth's munificent example, give the matter their very earnest attention, and see how far the union of local and private efforts can be made to aid in the movement. Provision should undoubtedly be made in several large centres of manufacturing industry for affording to all classes opportunities for acquiring instruction in the sciences which are applicable to productive industry. To carry this out, our leading manufacturers should act in concert and follow the example of Mr. Whitworth. Their combined efforts, supplemented by State assistance, would undoubtedly have the effect of substantially promoting technical education. Whilst we conceive that it is but proper that those having the deepest interests in its results should be the initiators of the movement, we must say that Mr. Whitworth has performed one of the most munificent acts on record. Looking to the results which may be expected to flow from it, this must be regarded as one of the most useful gifts ever offered to the nation.

THOMAS'S PHOTOGRAPHIC RESEARCHES.*

MR. R. W. THOMAS, F.C.S., a well-known photographer and photographic chemist, has just published a book called "The Modern Practice of Photography." The work contains some useful information for beginners, and here and there touches upon points of interest to advanced students, a chapter upon the permanency of silver prints being perhaps the best in the book. The advice to beginners is on the whole very good, with the exception of the directions how to prepare the nitrate bath. The author recommends that the free acid in the nitrate of silver be neutralized with oxide of silver, then that the bath be rendered slightly acid; also that iodide of potassium and alcohol be added to it before use. Though, by carefully going through these operations, a good bath may be produced, it is unwise to hamper beginners or older hands with such chemical manipulations. Much the best plan is to buy perfectly pure nitrate of silver in sealed tubes, in the first instance, and then there will be no trouble from the presence of free acid. With most samples of collodion, pure nitrate of silver dissolved in distilled water, and filtered, will give good pictures at once without further doctoring. Occasionally it is necessary to add a faint trace of acid to get clean pictures at starting. In some rare instances, new baths of plain nitrate of silver have a tendency to eat away some of the iodide in the film, and the best remedy is to iodize a plate, and leave it in the bath for three or four hours, when the liquid will satisfy its appetite for iodide of silver, and not injure plates afterwards immersed. The bath is continually taking up iodide of silver and alcohol from the collodion: hence it is a bad plan to put these substances in purposely at starting, unless the eating away of the iodide renders the additions necessary. The less iodide of silver and alcohol the bath takes up, the longer will it continue in working order, and the best plan of making a bath is simply to dissolve pure triple-crystallized nitrate of silver in distilled water, working the bath thus prepared with collodion rendered a light straw colour by the addition of a drop or two of a solution of iodine in absolute alcohol. The remainder of the instructions in the book are good.

On the question of the best method of securing permanent positive photographic prints, photographers are divided into two great classes, namely, into those who recommend the abolition of silver prints altogether, and into those who, by varnishing and analogous operations, seek to make the present pictures on albumenized paper more durable. Mr. Thomas thinks good silver prints to be more permanent than is generally believed. He thinks that the present large number of fading pictures has been brought about by the excusable chemical ignorance of photographers in the early days of the art; by the present great demand for cheap prints at unremunerative prices; and by the following of a beaten track in photographic printing, instead of striking out in a more original and philosophical path. After pointing out how greater permanency in silver prints has already been secured by the adoption of alkaline toning, freshly dissolved hyposulphite of soda, and thorough washing, he says truly that "the misdeeds of a former epoch are still a thorn in the flesh, and the confidence of those who would be buyers and collectors has been decidedly shaken."

The author next criticises the latest attempts to give permanency to silver prints, by impregnating them with varnish or collodion, and says that there is little chance of photographers using varnish either of known or unknown composition, especially as all varnishes sooner or later acquire colour, to the injury of the purity of the whites of the photograph. Moreover, photographs have been varnished before the present time, yet have faded in spite of the protection. The instability and perishability of collodion make it a very unsuitable substance to protect silver prints from the action of deleterious gases, and "fallacious experiments with sulphide of ammonium have been made for the purpose of proving the superiority of collodion over varnish, and for rendering prints permanent. This test is a mere snare and a delusion; it is not possible to anticipate the effect of time on such substances." This last remark strikes at the root of the matter, for it is evident that a waterproof varnish of collodion or gum may, when freshly applied, protect a photograph from the action of destructive vapours, yet at the end of a year be useless for any such purpose. Herein lies the cause of the little practical faith evinced by photographers in the schemes recently brought before the photographic societies, to try to protect the present prints by means of varnishes.

In order to secure greater permanency than at present, Mr. Thomas suggests that prints properly taken and washed in the first instance should be passed between steel rollers before instead of after being mounted on cardboard. He says:—"Consider for a moment the state of the paper, and the arrangement of the metallic particles forming the picture. The paper has been by the various operations loosened in texture, the size made more spongy—perhaps partially dissolved out—and the precipitate of silver salt, reduced by light, is in as divided a state as it is possible to conceive. But how easy, by means of suitable pressure, to alter this condition, and, not only to restore the paper to its original compactness, but, by compression of the silver particles, bring about a change of structure which shall then more nearly represent a compact metallic layer, no longer

* "The Modern Practice of Photography." By R. W. THOMAS, F.C.S. London: Harrison, Pall Mall. 1868.

Digitized by Google

absorbent, and easily acted upon by every deleterious breath." He then points out a few familiar illustrations of the fact, that substances in a state of fine division yield more readily to chemical action than when in a compact state. Enough pressure to produce the desired result can evidently not be applied to the photograph after it is mounted on cardboard.

The writer next recommends that the photograph shall be mounted with india-rubber in solution, and not with paste or glue, so that the pores of the paper may be filled up with an insoluble material. Lastly, he recommends that the surface of the photograph shall be waxed. He does not like the application of the numerous solutions of wax which have been recommended for the purpose, as the liquids give a flat and unctuous appearance, very disagreeable to the eye. He says that "a cerate, composed principally of oil of lavender and wax, sufficiently firm to admit of its being conveniently rubbed into the surface of the print with a suitable brush, is by far the best and most convenient preparation to use. Half a minute's application for a small picture is enough. It should be rubbed perfectly over the surface of the photograph. Sufficient may be used to leave a slight excess unabsorbed; it need not be made to penetrate beyond the layer of albumen, although it should be well rubbed in; the print is not, therefore, rendered translucent by its application. Let the photograph so prepared remain half an hour before removing the excess with a suitable rubber. Before applying the cerate take care that the photograph be thoroughly dry." A photograph so treated may be polished, when dry, by means of a tuft of cotton wool.

The foregoing directions are about the best that could possibly be given, in the present state of photographic knowledge, to secure greater permanency in the silver print, and it is not impossible that pictures so protected may last nearly a lifetime without change, though exposed daily to air and light. Nevertheless, all past experience warns us to place no trust on the stability of any silver print, where the possessor desires to secure a photograph as permanent as the writings of the monks of old, who, for the most part, employed carbon inks. The most permanent prints upon paper which photography can at present produce are those taken by the carbon process, but this process is better adapted for large than small pictures. The system of silver printing is so deeply established by time and custom, that the real remedy for fading photographs rests principally in the hands of the general public, who may secure permanent prints by creating a demand for carbon pictures, and expressing a willingness to pay for the same at higher rates. The supply will soon follow the demand.

HARBOUR WORKS IN THE NORTH.

VERY recently it has been stated, upon good authority, that the shipbuilding trade, and the numerous minor branches of industry connected with it, are migrating in a northerly direction. Business is leaving the shores of Old Father Thames to establish itself upon those of the Clyde. The causes, of what appears to be true in the main, we need not now inquire into, but if the fact is palpable, and the departure permanent, it is evident that those who are likely to suffer from the circumstance should make up their minds to go after the work, provided the work is really there for them to do. It is futile to remain in a place with the hope of obtaining employment, when that very employment has betaken itself to another locality, and more especially, when there is, at any rate, no immediate prospect of its return. Whether it is, that the more northern parts of the kingdom possess peculiar advantages with respect to site, facility for acquiring land, and obtaining material, or that for other reasons labour is cheaper and more abundant, yet it seems to be acknowledged that work can be carried on there with greater economy than in the immediate proximity of the metropolis. From early times the Clyde has always been renowned for its reputation in connection with shipbuilding and shipping matters. Some of the largest as well as fleetest vessels have received their baptism on its shores, and taken their first plunge in its waters, and but for the skill and industry of its shipwrights, our privateers would not have been so fortunate as they were during the days of legalized buccaneering.

It is but yesterday that the new Millwall Docks were opened, and as if it were with the intention of keeping pace with any new harbour or dock works here, we find that large and important additions are to be made to the existing marine accommodation upon the Firth of Clyde. The trustees of Greenock Harbour have determined upon carrying out several extensive works, which have for a long period been considered almost indispensable to the shipping interests of that port, which at present is unable to adequately provide for the reception of vessels exceeding 1,500 tons register. It is proposed to construct a couple of wet docks or tidal harbours and a large graving dock, the latter requirement being the most urgent. Its dimensions will be considerable, and if the proposed extension be ultimately carried out, it will be capable of berthing the "Great Eastern." At present, however, it is not intended that the length should be greater than 500ft., a further length of 250ft. being left to the future. The breadth at top will be 90ft., and at the level of the gates about 66ft., and the depth at the top of the blocks not less than 18ft., at high water. The new graving dock at Millwall has a length of 420ft., and a breadth of 65ft., and is not entered directly from the river, but lies to one side of one of the wet docks. In the present instance, a direct communication with the Clyde is objected to by the Greenock harbour trustees, and there is very little question that, wherever it can be done, a basin or dock should separate a graving dock from the immediate foreshore. The wet docks or tidal harbours will have a depth, at high water, of at least 25ft., and those interested in the success of the proposed undertaking have not forgotten that it is imperative to bring it into direct communication with its near neighbour the Caledonian Railway. Harbours and railways are close allies, and it is only by effecting a junction between them that a country can hope for a prosperous exchange of imports and exports.

NOTICES OF BOOKS.

AMONGST the numerous benefits conferred on patentees and inventors by the Literary Department of the Patent Office, first and foremost stands that of enabling those who require to consult the specifications to do so with comfort and convenience, and without loss of time, either in their own offices or in the Patent Office Library. This is effected by means of a series of abridgments which have been made under the able direction fo Mr. Bennet Woodcroft. In these admirable conpilations the subject-matter is classified and treated chronologically, thus enabling anyone to search through a subject continuously without having to consult each separate specification. By these abridgments the reader is at a glance placed in possession of the pith of the invention; should he wish to enter upon the details, of course he will refer to the printed specification, where he will have the matter *in extenso*. The volumes before us contain abridgments of inventions under the several heads of "Preparation and combustion of fuel;" "Raising, lowering, and weighting;" "Railways," and "Hydraulics." These books are invaluable to inventors and others to whom the "Indexes to Patents" have become indispensable, inasmuch as the indexes are now very numerous and proportionately expensive, whilst the abridgments are compact and as cheap as they can be produced. The only thing we cannot understand about them is that the volume on the preparation and combustion of fuel, which contains 1,407 pages, should be charged 17s., whilst that on hydraulics, which contains 1,440 pages, can be had for 15s. The specifications are charged for according to amount of matter and size of drawings, and we should have thought similar conditions would have governed the prices of the abridgments. Each of the volumes before us, except that on railways, has an appropriate and well-written introduction, giving an outline history of the subject it precedes. Each has also an ample index, and each should have the subject-matter noted on the back for readier reference when placed on shelves.

Mr. John Timbs' "Year Book of Facts* in Science and Art" is now so well known and appreciated, that the simple announcement of its appearance might suffice for the majority of our readers. But as there are always some to whom a little detail information is welcome, we will give them the general scope and features of the work. In the well-arranged volume before us, Mr. Timbs embodies the most important discoveries and improvements of the past year. These are culled from various sources—our own pages amongst the rest—the authority in each case being duly acknowledged. The range of subjects is very wide, embracing mechanics and the useful arts, natural philosophy, electricity, chemistry, zoology and botany, geology and mineralogy, meteorology and astronomy. The volume for this year contains an interesting memoir of Sir Samuel Baker, an excellently-engraved portrait of whom faces the title page. Notices of the Royal Albert Hall of Arts and Sciences, the Paris Exhibition, the Alexandra Palace, and the Albert Memorial in Hyde Park, are followed by a series of judiciously-selected articles on the various subjects we have enumerated. Mr. Timbs is very happy, both in his selection of subjects and condensation of matter. With such a wide field as he has to work upon, it is no easy task to make a proper choice of material. Mr. Timbs, however, succeeds well in every respect, giving a large amount of varied information, and bringing each subject within a very small compass. If anyone wishes to know what progress science has made, or what has been done in any branch of art during the past year, they have only to turn to Mr. Timbs' pages, and they are sure to obtain the required information.

Our opening remarks upon the previous book apply also to the fifth volume of "Engineering Facts and Figures"† which is now to hand. This work is similar to the last in design, although in its detail arrangement it widely differs from it. In the present instance we have strictly a record of engineering facts, indeed, the volume purports to be an annual register of progress in mechanical engineering construction. It is ably compiled from various engineering journals, and includes papers read before the scientific societies. A special feature this year is a series of useful notices of several of the departments of the Paris Exhibition, and these occupy a considerable portion of the volume before us. The value of this work consists in its entering widely into detail upon a select branch of engineering science—the mechanical—the knowledge of the previous year being gathered up and classified under the various heads to which it pertains. The illustrations this year are in advance of those of past volumes, and include a number of lithographed drawings besides wood engravings.

The question of the petroleum discoveries in Italy has been made the subject of an interesting treatise,* by Mr. E. St. John Fairman. It is the result of a geological tour through Italy taken by the author in 1865, in the course of which he particularly turned his attention to petroleum. Mr. Fairman has collected a large amount of evidence which favours the prosecution of the petroleum enterprise in Italy. He has explored the petroleum zones between the south of Milan and the south of Bologna, and along the confines of Modena, and has detected the undoubted presence of petroleum. In other parts he has been equally successful, having found even the sandstone of Monte Baranzone and other mountains to be strongly impregnated with oil. With regard to the commercial value of Italian petroleum, it is to be observed that Professor Chandler, of the School of Mines, Columbia College, New York, gives the following report of its analysis:—While the Pennsylvania oils contain on the average 10 per cent. of gasolene, 10 per cent. of naphtha, and only about 75 per cent. of illuminating and lubricating oils, the Italian oils are remarkable for the entire absence of gasolene, and in many cases of naphtha, the yield of illuminating and lubricating oil reaching from 88 to 97 per cent. This is greatly to the advantage of the Italian oils, as gasolene and naphtha bring very low prices in the market. The Italian oils are also distinguished by the absence of the offensive odour which characterizes most of the American petroleum. Not one of the ten samples is disagreeable, while several of them are almost odourless, a circumstance which will tend to simplify the process of refining. The light colour of most of the samples is equally striking. In the reports of the analyses, all the oils having a density below 36deg. Baumé have been recorded as lubricating oil; the skilful refiner has it in his power to convert a great part of this into lighter illuminating oil by 'cracking' (re-distilling very slowly) it, whenever the comparative market prices of the two oils make it profitable to do so. It must not be supposed, therefore, from the analyses, that the Italian oils will not yield much illuminating oil, for, on the contrary, they possess a great advantage in their weight, which makes it possible to obtain from them an unusually large yield of either illuminating or lubricating oil at pleasure." Professor Ansted also reports very favourably of the Italian petroleum. Mr. Fairman's treatise will be found very interesting, especially to those who may be able to promote the development of the petroleum question in Italy. The author believes in the feasibility of this, and that it will yet prove to be the most fruitful source of revenue to that country.

Mr. Watts' valuable contribution to chemical literature—"The Dictionary of Chemistry"†—is fast nearing completion, parts XLII., XLIII., and XLIV. being now before us. The subjects range from the article on terbium to that on water. There is an excellent article—or, rather, a series of articles—on thallium, by Mr. Watts, in which all its compounds are fully dealt with. An article on tin, by Professor Field, is well worthy of perusal, drawings of the furnaces being given. The compounds of this metal are thoroughly considered in succeeding articles. The subject of tungsten is also exhaustively treated, and is well worthy the notice of the producers and users of iron and steel. Chemists will find much to interest them in an elaborate article, by the editor, on uric acid, no artificial method of producing which has yet been discovered. Vanadium and the vanadates—so far as they have been examined—are also considered at length by Mr. Watts, to whom too much credit cannot be given for the excellent manner in which the whole work is being brought out.

Amongst the minor productions of the press, we have before us the second annual report of the Aeronautical Society of Great Britain for 1867 (S. Richardson, Greenwich). It has been prepared by the indefatigable hon. secretary, Mr. F. W. Brearey, and contains an account of the proceedings of the Society, and a selection from the papers and communications read and received during the year. The concluding remarks bear upon the present state of aeronautical science, which is certainly defective, and which it is hoped may be improved by the forthcoming exhibition at the Crystal Palace. A warning voice is uttered by "An Engineer" to the people of England on the present crisis, in the form of a series of letters reprinted in pamphlet form from "The Engineer," by Mr. Waygood. He attributes the badness of times to exhibitions and bad legislation, and suggests remedies, discussing the subject of technical education at some length. Mr. A. W. Cunningham contributes a treatise on the history, methods, and technological importance of descriptive geometry (Edmonston and Douglas, Edinburgh). The object of the writer is to enforce the importance of study in this direction in connection with the important and all-absorbing topic of technical education. We commend this pamphlet to all who are, or who may presently be, engaged in carrying out the details of this imminent step in the right direction. Mr. Edward Thornton propounds a method of finding a square exactly equal in area to a given circle. All those of our readers who wish to prove the question with the author will do well to obtain his pamphlet from Mr. Stanford, of Charing-cross. Of course, Mr. Thornton squares the circle exactly.

It is very pleasant to turn from the harder and more abstruse points of science to its simpler phases, as depicted in "Hardwicke's Science Gossip" (Hardwicke, Piccadilly). Month by month this interesting work comes to us full of fresh wonders and pleasing facts. Its illustrations, too, are both improving and increasing, and the spirited proprietors leave "students and lovers of nature," to whom the work specially appeals, nothing to desire—except the next number. The enterprising firm of Cassell, Petter, and Galpin are bringing out a new edition of their "Popular Educator," which has been revised to the present time. It is now some twenty years since this work was first issued from the press, during which time it has enjoyed a well-merited popularity. It has rendered efficient services in the promotion of national education, and we wish it that success in the future it so thoroughly deserves. If any wish to know the aim of the work, they here have it in the words of the proprietors. In their introduction they say:—"To amuse, to instruct, to elevate, will be our constant endeavour. To render the workman more perfect in his vocation, the soldier and sailor better fitted for the higher positions of his profession, the naturalist more conversant with the beauties of Nature, the politician further acquainted with the important events in the history of his country, and to place at the command of the student for the Civil Service or University examinations all the branches of education necessary for his advancement, no effort will be wanting. Our ambition is to place in every English home an educational encyclopædia, invaluable as a manual of study and a work of reference, which, whilst simple, progressive, and interesting in its style, shall be powerful for the improvement and the advancement of its students."

To those of our readers who take an active interest in the social improvement and moral elevation of their workpeople and dependants—and who does not?—we heartily commend the popular illustrated works of Messrs. Partridge and Co., of Paternoster-row. Foremost amongst these we would place the "British Workman" and the "Band of Hope Review." These publications are marvels of cheapness, and our wonder is how such engravings—spirited and bold in conception and finished in execution—can possibly be given for the price. These papers are calculated to do, and we believe are doing, much good amongst the working classes, and we gladly recommend them to notice. We cannot conclude without noticing a plan for a central Courts of Justice palace, which has been designed by M. Vericchio. The plan is very simple in its arrangement, being nothing more than a square divided and subdivided, *ad infinitum*. But how far the design meets the requirements of the case, or how far it is compatible with the site to be covered, we leave to those who have closely and patiently studied the matter to say.

NOTES ON RECENT SCIENTIFIC DISCOVERIES AND THEIR PRACTICAL APPLICATIONS.

THE EXAMINATION OF ARTIFICIAL FUELS—VELOCITY OF THE PROPAGATION OF SOUND IN TUBES—THE ANALYZATION OF NOISE.

A METHOD of examining chemically artificial fuels is described in the "Bulletin de la Société Chimique de Paris," and may be worthy the notice of some of our readers. Its object is to determine the nature of the agglomerating material which may add little or much to the heating power of the fuel, according to the nature of the substance employed. The author assumes that some sort of pitch or bituminous material will be used; but this is not the case, at all events, in all English artificial fuels. In the course of the investigation described the author first reduces a brick of the fuel to a fine powder, and exhausts a given weight with bisulphide of carbon. In this liquid all sorts of pitch and bitumen are completely soluble, and the solution carefully evaporated will give the whole amount of agglomerating material. For the information of any reader not acquainted with bisulphide of carbon, we must add that the evaporation should be carried on over a water-bath, and in a good current of air, the vapour being highly inflammable, and igniting at a comparatively low temperature. The residue left after the complete evaporation of the bisulphide having been weighed to ascertain the whole amount of the pitchy matter present, is next heated carefully to 300deg. or 400deg. Fah. Any loss of weight at this temperature will indicate the presence of the lighter coal products, and show that gas tar has been used to bind the coal-dust. If no loss of weight is found at the temperature mentioned the heat is carried to 600deg. Fah., and the loss then will be the heavier oils, and it may be inferred that a so-called "fat pitch" has been used. The above outline will serve to show the course of investigation pursued, which will give some idea of the calorific power and value of the fuel.

Kundt has made an elaborate investigation into the various circumstances which influence the velocity of the propagation of sound in tubes, the results of which may have some interest to the makers of wind instruments. He has established, in the first place, that the velocity diminishes with the diameter of the tube. The diminution, however, only becomes sensible at a given diameter, which is equal to one-fourth of the length of the wave of sound or note yielded. Above this diameter, and in all larger tubes, the velocity remains invariable. Starting with the diameter we have mentioned, Kundt finds that the diminution of the velocity of sound in tubes full of air increases with the length of the wave of sound employed. He made further the curious observation that fine powder in the interior of a large tube had no effect on the velocity of transmission, but that in tubes of small diameter the velocity decreased in proportion to the quantity of powder, and that the lighter the powder the greater was the retardation. The substance which had the greatest effect on the velocity he found to be the extremely light powder obtained by drying gelatinous silica. Lastly, the author has found that the velocity of

* "A Treatise on the Petroleum Zones of Italy." By E. ST. JOHN FAIRMAN, F.G.S., &c. London: E. and F. N Spon. 1868.]

† "A Dictionary of Chemistry and the Allied Branches of Other Sciences." By HENRY WATTS, F.C.S., &c. London: Longmans, Green, Reader, and Dyer. 1868.

Digitized by Google

the propagation of sound in a tube is not at all influenced by the intensity of the sound, and that roughness or smoothness of the interior has no effect in either retarding or accelerating the rate of transmission.

While writing on the subject of sound, we may mention the curious instrument, invented by M. Daguin, which he calls an "analysing cornet." What we describe as noise is, of course, made up of an infinite number of notes, which it is the business of M. Daguin's instrument to disentangle and separate, as a prism analyses a ray of white light, and displays its coloured components. Full details of the instrument are yet wanting; but the one exhibited to the Academy of Sciences appears to have been in shape something like a guard's horn with a nozzle to fit into the ear, instead of a mouth-piece, and furnished with holes like a clarionet. With an instrument like this in his ear, or with one in each ear, the listener practised in the necessary fingering, may sit, and from the roaring of the cataract or howling of the storm, extract a soft melody, which is heard only by himself. Delightful, but selfish enjoyment!

THE INSTITUTION OF NAVAL ARCHITECTS.

THE annual meeting of the Institution of Naval Architects commenced on Thursday last at twelve o'clock, and concluded on Saturday. The meetings were held in the hall of the Society of Arts. In the absence, through illness, of the Right Hon. Sir J. S. Pakington, Bart., M.P., &c., President of the Institution, the chair was taken by J. D'Aguilar Samuda, Esq., M.P., treasurer. Among those present were Sir Ed. Belcher, Mr. Scott Russell, Earl Lauderdale, Dr. Woolley, Admiral Halsted, Mr. E. J. Reed, Mr. Rochussen, &c.

Mr. Merrifield, the Hon. Secretary of the Institution, then read the following report of the council:—"The council have great pleasure in congratulating the Institution on the useful work which it has done during the past and previous years. The volume of the 'Transactions' which has just been published, contains, in addition to the usual store of valuable papers and discussions, an index arranged under the names of the authors of the papers and of the gentlemen who took part in the discussion. The financial position of the Institution has received the serious attention of the council. Application has been made to her Majesty's Government for an annual grant in aid of the funds of the Institution, and although no official answer has been received it is understood that it is still under the consideration—it is hoped the favourable consideration—of the Treasury. The offices of the Institution still remain at 7, Adelphi-terrace, but the council are informed that their tenure is only temporary, in consequence of the alterations which the completion of the Thames Embankment will involve in the approaches and adjacent buildings. But due notice will be given when a removal becomes necessary. The School of Naval Architecture and Marine Engineering, at South Kensington, is still watched with great solicitude by the council. They are happy to state that it progresses favourably, and that the number of ordinary students is increasing year by year. Her Majesty's Government have not thought fit to appoint the commission of inquiry into the safety of ships, for which the council of the Institution had applied. But it is understood that an Amendment Bill for the Merchant Shipping Acts is to be submitted to Parliament this session, and the recommendations of your council will doubtless receive due consideration."

The chairman then delivered the following inaugural address:—Gentlemen,—It is a matter of duty that I feel obliged to intrude myself upon you on the present occasion. I deeply regret that you should have been prevented from having the presence of our president here to-day, and I regret it the more on account of the circumstances which have caused our disappointment. And I regret, in common with you all, that we are prevented through his absence from having the advantage of that address which he no doubt would have given, and which he on all previous occasions has so ably laid before us to guide our proceedings and to direct us in these matters. I still hope, however, from a letter which has been received from Sir John Pakington, that the Institution may not be altogether prevented from having the advantage which it has in previous years received at the hands of our president. He still in his letter expresses a hope that he will be well enough by Saturday to be among you, and I hope that you and I shall not be prevented on that occasion from having the advantage of hearing his address, and that all the shortcomings which must necessarily attend that which I would make to you to-day will be on that occasion supplied by our president. I must crave your indulgence on many points—one more especially, because as I have been asked to preside only within a few minutes of entering into the room, many of the matters which are coming before us are somewhat strange, and of course I am less intimately acquainted with them than I could have hoped to be before venturing to speak to you upon them. The first thing which calls for our especial attention is the financial position of the Institution. The financial position of the Institution, you are most of you aware, has never been in a particularly flourishing condition; but there are circumstances connected with it which leads me to hope that it is far from retrograding at the present moment. Without troubling you with any figures, I may state that the general position seems to be this—that the deficiencies which we had in 1867 were somewhat short of £200, while from the estimated financies of the present year, taken very carefully, it appears as though the receipts would very nearly, if not quite, balance the expenditure. There are expectations, which I hope will be realized also, of some advantages with regard to assistance from Government, but as those are at present only in an embryo state I think it would be well not further to refer to them.

The next matter which I have to enlarge upon to some extent is one of a very much more satisfactory and favourable character—that is, the School of Naval Architecture. Now, the School of Naval Architecture appears to be progressing very favourably. The increased number of private students this year has been five; the total number of students altogether is forty-two. The Admiralty are making some change in their arrangements for sending the pupils here, which therefore may, perhaps, if referred to the mere comparative numbers of this year and last, lead to an erroneous idea as to the advantage which is being taken of the Institution; but it will be sufficient to say that so far from that being diminished—so far from there being an under estimating of the value of the school—the Admiralty are seeking to avail themselves of it in a larger degree than previously, and that the operation which is taking place at this present moment is merely that of changing a certain number which was fixed on in the first instance, to a rateable and regular number to be supplied every year; and it is the intention of the Admiralty by this equalizing process to send ten new students, each of them to be engaged for a course of years; and, consequently, the Admiralty students at the establishment will be maintained generally or entirely at the point of thirty. The references which we have had show that a considerable number of those pupils which have left the school, and who are now in the service of the Admiralty, are giving the greatest satisfaction to their officers; and there is generally equally satisfactory information received with regard to those who go into private yards; and when, as in the present day, so much importance is attached, both by the Legislature and by the public, to the advantage of practical, or what is called "technical education," I think that this Institution may take some credit to itself for having to a very great degree pointed out the direction which that technical education should follow. Now, for my own part, if by "technical education" is to be understood that which is by a great many of its advocates understood, namely, education in a particular and a single direction for the purpose of following a special profession or trade, then I believe that technical education will entirely fail and miss its object; but if by "technical education" is to be understood that which I think we do accomplish in this Institution—namely, upon a sound education in the first instance, the superadding the opportunity of practically working at that trade or occupation which it is intended you should acquire proficiency in, then I believe that technical education is one of the highest advantages that you can give the learner. Now that is accomplished in this Institution, for I believe the Institution are fully aware that all the students at this college have the means given to them, wholly apart from the instruction which they receive in the establishment, of visiting the dockyards and working in the dockyards at the works there to be performed—the practical works—not at models or theoretical works, but at the practical works that are going on for the country, exactly the same as all the other artizans there employed. That is a point to which I would address my observations, as being, in my opinion, of such a highly important nature, namely, that of superadding to a general education nothing short of the real and absolute work which is to form the staple part of a man's life.

The next subject to which to draw your attention in the report of the council is that which has reference to the interesting subject of the safety of ships, which this Institution will recollect arose in consequence of a reference made by our president, at the previous annual meeting, to the disastrous effect that had occurred from the loss of the steamship "London," and of the admirable recommendation which followed his observations on that catastrophe of the great desirability of seeing whether the professional knowledge of this country, as concen- in this Institution, could recommend such means as would practically avoid future disastrous results. The council of the Institution met, and at very considerable length, and with a very great amount of care and attention they investigated the whole matter. Many of the members engaged in that inquiry looked at it from one point of view and some from another, but all with the same object—that of seeking, if possible, to arrive at some means by which the public could be protected against similar catastrophes. The result of the inquiry is to be found in the elaborate report which is given in the volume of "Transactions" which is now in your hands, and I think it is not too much to say that there is scarcely a paragraph in that report but what is pregnant with suggestions of the very greatest value for reflection and thought. The only thing which appears to me upon the face of this report to require consideration—and that probably, I may say, a balanced consideration—one which has considerable advantages and disadvantages—is whether, having arrived at all these recommendations, those recommendations should be allowed, on the one hand, to weigh in the minds of persons engaged in marine construction, and to guide them in such conclusions as, having the advantage of that information before them, they may come to, or whether they should be embodied by the Legislature in a stringent legal provision compelling persons to follow some particular rule that may be laid down for them. Now, I must say that I am one of those who consider that it would be a great misfortune for the country if we attempted by legislation to restrain the exercise of that amount of thought and that amount of responsibility which make, in the main, the character of all those who are engaged in any very great professional works; and, I think, therefore, that instead of being a subject to be regretted, it is, probably, one that should be looked upon from another point of view, when we find that her Majesty's Government have not up to the present moment embodied any such instructions in a legislative or an authoritative and directing form. We do infer the fact that there is to be an amended Shipping Bill. What that amended Shipping Bill contains we do not profess to know; neither do I apprehend that we at all wish to convey to you that we wish in that Shipping Bill to find an absolute and restrictive plan laid down by the Government for all constructions as rules to be followed. At any rate, I will venture to do this—to disengage myself from that observation so far as to point out my own views upon that subject. I should hope that whilst every care was taken by the Government at all times to protect the public from the possession of that which is bad, the greatest care would be taken by them to avoid that direction of construction which might lead to a very much worse result in the long run by removing the responsibility which now exists, and which in my opinion ought to exist, solely upon those professional parties who undertake the responsibility of these works.

I think, now, that having passed by our report I might be permitted perhaps just to glance at the programme which is now before us. On that programme, judging by the titles of the papers which we have to discuss, will be found, I think, some of the most interesting and some of the most important subjects that can be brought before us as naval architects. The very first one that we have to discuss may be treated, and I hope will be found to be treated—I have not myself seen the paper at all—in a way to engage the most serious attention of this Institution. I conceive that there are few things at the present time that are of more importance in the consideration of naval constructors than a proper appreciation and a proper use of what I may call the new material, steel. Of course we know that in one sense steel is no new material. In one sense it has been known from the most ancient periods of history and almost of the world. But the production of steel lately has taken such a form from that which it took formerly as to enable it to come within that compass of price that will render it an ingredient of great value in shipbuilding, and I do not think that its value is even at the present moment sufficiently appreciated. This may probably result from the fact that some

Digitized by Google

difficulties have occurred, and may not perhaps be altogether overcome even at the present moment, in the production of it. But I do think that the advantages to be gained from steel are so great that they ought to be fully and entirely recognized, and I believe that in that, as in all similar cases, when these advantages are once fully recognized by the public, the little difficulties in the manufacture that exist at the present moment, if they have not been already overcome, will be overcome, and that the advantages of this material will tend immensely for the public good.

I may probably just be allowed to say that, so long ago as immediately after the close of the Crimean war, nine or ten years ago, I had occasion to build in steel. At that time steel was beginning to recommend itself by what was called "puddled steel." Well, puddled steel was a very doubtful description of material. The process was one which necessarily involved a great deal of risk in the production of the finished material, as time was an ingredient, which time could be measured in practice only in the working of the iron converted into this steel. In fact, I should say that I had tried puddled steel, seeing the great advantages that were to be obtained by using a lighter material with a very much greater amount of strength for its comparative weight; and I had found these difficulties attending puddled steel, namely, a want of uniformity in its texture and strength. But having had my attention directed to it, I went at once to what I conceive to be the only way of dealing with a case where the absence of weight was absolutely necessary—that is to say, where steel could be used which could be absolutely relied upon for its strength; and I had to pay for the steel which I used in a sea-going vessel which I then constructed £50 a ton. But the whole of the steel was cast steel, manufactured by the usual process in which the ordinary cast steel bars are manufactured in little charcoal pots, and it could not be produced at that time for a smaller sum. It is a satisfactory thing to know that though that price would have put the use of the material completely out of the range of all commercial persons for ordinary purposes, the vessel then constructed (a vessel of 500 tons) has been working from that time to the present in a very rough sea—that is to say, the Black Sea; and there was not a single plate in this vessel of 500 tons greater in thickness than 3-16in. I have most accurate reports of the state and condition of the material in that vessel at the present time; and if these reports are true (and I have every reason to believe them to be accurate), the vessel is as perfect now as it was at the time it left England. Well, the introduction of the different processes which have been devised—Bessemer's process, for instance—has so materially reduced the price of this material that you are able to get an equally good material for £20 a ton with that for which I then had to pay £50. Now, this material which at this present moment you get at £20 a ton may generally and roughly be compared with iron in this way—that its general tensile strength may be taken to be at least twice as great. One may be taken as 40 tons to the inch, whilst the other may be taken at 20 tons to the inch. And the ductility of the steel, when properly produced, is very much greater than that of the iron. Therefore, you really have this great advantage laid before the constructor for his consideration—and it is in this view especially that it interests us as naval architects—that after you have made all allowances—and I put this suggestion to prevent you from jumping too quickly to the conclusion that you can in all circumstances adopt it—after you have made due allowances for the difficulty of obtaining uniform perfection throughout this steel, you have a field open before you to encourage the steel manufacturer to produce perfection with the knowledge that if he does so he can relieve the vessel by one-half of the weight of the iron put into it, and thus he can enable you as a commercial man to utilize the difference of weight by the carriage of extra cargo. Or, if your object be speed, he can enable you to attain the same rate of speed with a lower amount of power, or, what is equivalent, a much higher speed with the same amount of power. Therefore, any paper which brings before us the importance of steel is of vast importance to the "Transactions" of this Institution.

The next subject which we have upon our paper is also one of very great importance. It seems that the general subject which we have to discuss on these occasions is, in one shape or another, the further development of the construction of ships of war. This has always been since the time of its birth—now some ten or twelve years ago—a subject of great importance, and one which is far from flagging in its interest. I think the general admission will be that it is one which grows daily in importance, and daily attracts more and more attention, particularly of those engaged in marine operations. I should hope that these papers that we have before us, attached to which I see names which are an earnest that they will convey to us most valuable information, will not only repay us the opportunity and the time that we shall devote to listening to them, but will very considerably add to the general knowledge on this important subject. Finally, gentlemen, I hope I may be excused for having kept you so long in dealing with those subjects, and I hope that you will further excuse what I feel bound at the present opportunity to tell you, which is, that not having been aware that I was going to be asked to fill the honourable position in which I find myself this morning, I had made those engagements which I now find it absolutely impossible to avoid; in fact, they are connected with parliamentary duties—and, therefore, after the reading of the first paper I shall be obliged to crave your indulgence to allow me to retire; but I have an opportunity of saying that on this occasion Lord Lauderdale has kindly consented to take the chair for the remainder of your meeting.

INSTITUTE OF CIVIL ENGINEERS.

AT the meeting of the Institution of Civil Engineers, held March 31, 1868, Mr. C. H. Gregory, President, in the chair. The paper read was on the City Terminus Extension of the Charing Cross Railway, by Mr. John Wolfe Barry, M. Inst. C.E.

This line was authorized by Act of Parliament, dated June 28, 1861, and the works comprised (1) a bridge over the river Thames, (2) the Cannon-street Station, and (3) viaducts south of the river, for connecting the bridge over the Thames with the main line of the Charing Cross Railway.

The bridge over the Thames had been constructed to carry five lines of way from the south abutment to the pier next to the Middlesex shore, at which point the five lines branched out, and were connected with nine lines of way in the station. There were two footpaths, one on each side of the bridge, intended for the use of the public on payment of a small toll, but they had not yet been opened for traffic. The extreme length of the bridge between the abutments was 706ft. This length was divided into five spans, the two side openings being each 125ft., and the three centre openings being each 136ft. in the clear on the centre line. The width of the straight portion of the bridge outside the footway parapets was 80ft., and the width of the railway portion between the inside parapets was 61ft. 8in. The fan, which extended over the Middlesex opening, was widened out to 202ft. at the abutment, and accommodated, in addition to the lines of way, portions of two passenger platforms, engine sidings, foreman's offices, &c. The height of the soffit of the bridge above Trinity high-water level varied from 24ft. 8in. at the abutments to 25ft. 4in. in the centre span. The object of this arrangement was to prevent the bridge appearing depressed at the centre. The height of the rails above the soffit of the bridge was 9ft. 10in.

The southern abutment was built on cast-iron caissons, sunk side by side, partly by means of divers working in helmets, and partly by dredging inside the caissons with a bag and spoon dredger. In the case of the north abutment, neither caissons nor cofferdams were used; short lengths of ground were excavated at low water, a small "stank" dam of clay was employed, and the water being pumped out as the tide ebbed, the excavation was continued and the footings were got in. The piers were each formed of four cast-iron cylinders, placed in a line at right angles to the longitudinal axis of the bridge, and connected by two wrought-iron transverse girders at the top. The outside diameter of the cylinders was 18ft. below and 12ft. above the bed of the river; a conical reducing ring being introduced to effect the junction between the two diameters. The cylinder plates were fluted from 5ft. below Trinity high-water mark up to the level of the ornamental cap mouldings. In sinking the cylinders, the bed of the river was first smoothed by dredging; then the two bottom rings, together 13½ft. in height, which was equivalent to the greatest depth of water at low tide, were put together on timbers, between strong timber guides, exactly over their destined position. This portion of the cylinder was next raised by a travelling crane so as to permit the removal of the supporting timbers, and was afterwards lowered into position. A third ring of plates was then added, and a bag and spoon dredger was employed inside the cylinder, to take out the mud and gravel As the cylinder descended additional rings were bolted on until the London clay was reached, when the sinking was continued by ordinary excavation until the final depth was attained, which was from 59ft. to 65½ft. below Trinity high-water mark.

The cylinders were filled with Portland cement concrete up to the level of the bottom of the reducing ring, and on this, brickwork, also in Portland cement, was carefully built for the full height of each column, being capped with large bed stones 2ft. thick. Each of the cylinders was weighted at the testing line with 850 tons of iron. This weight was calculated to represent the dead weight of the structure above that line, a rolling load of one ton per lineal foot for each line of way supported by the cylinder, and a moving load on the footpaths. The order to remove the load was not given until it was ascertained that no subsidence had taken place for seven days. The greatest subsidence under the full test load was 2⅜in., and the least ⅛in. The heaviest weight on the London clay at the bottom of any of the cylinders was 5·84 tons per superficial foot, with a rolling load as stated; and the heaviest weight on the brickwork in the cylinders was about nine tons per superficial foot.

The particulars were next given in detail of the bed-plate girders, of the outside main girders, and of the intermediate main girders. The girders for the two side openings were independent of the other spans, but those for the three centre spans were continuous over the three openings. The flooring of the bridge was composed of flat plates of wrought iron ½in. thick, which were riveted to the top flanges of the main girders, and were further strengthened by angle or T irons; for as the floor of the bridge formed the station yard, and was occupied by cross roads, as well as by the through lines, it was necessary that it should be capable of carrying the rolling load in any direction. Upon the flooring plates asphalte was laid, which was covered with an average thickness of 5in. of ashes, as ballast, and on this the ordinary permanent way was placed.

The piers of the bridge, from the bottom of the cylinders to the bed-plate girder, contained in all about 2,500 tons of cast and wrought iron. The superstructure contained about 4,200 tons of wrought iron in girders, floor-plates, &c., and about 1,100 tons of ornamental castings. The cost of the Cannon-street Bridge, including the abutments, signal bridge, and all things connected with the work, with the exception of the permanent way, signals and signal apparatus, gas and water mains, amounted to £193,000. This sum gave £2 15s. as the cost per superficial foot, and £250 per lineal foot, or £50 per lineal foot for each line of way, including the fan and footpaths.

The length of ground occupied by the Cannon-street Station, between the river Thames and Cannon-street, was 855ft., distributed as follows:—The forecourt was 90ft. wide, the booking-offices were 85ft. wide, and the length of the covered portion of the station south of the booking-offices was 680ft. The width of the station outside the walls was 202ft., and inside the walls, at the platform level, it was 187ft. The whole of the station was built on a substructure of brick piers and arches, excepting the booking-offices and the part which was over Upper Thames-street. At the crossing of this street, which passed underneath the station at about midway of its length, wrought-iron girders were used. Openings were left in all the piers, to allow tramways to be worked throughout the basement if necessary; and provision had been made in the arches for an hydraulic lift to raise and lower the waggons. The cross openings north of Upper Thames-street were mostly carried up through the springing of the large arch, and were groined into it. The groining, which was 27in. thick, was built in Portland cement, and the keystone was of Bramley Fall. It was adopted in consequence of the height of the ground not allowing communication between the different main archways, by transverse arches below the springing of the large arch. Without intercommunication the value of the vaults would have been commercially much diminished, and they would not have been available, as they were now, for parcels offices, stores, and railway purposes. The station walls were almost entirely of brickwork in mortar—the only exceptions being the arch over Upper Thames-street, and a few courses at the top of the walls, which were laid in cement.

The main trusses of the roof consisted of segmental ribs with a tie-bar looped up. The clear span of the trusses was 190ft. 4in. The rise of the rib at the centre was 60ft., and the rise of the tie-bar was 30ft. The truss was, therefore, 30ft. de

Digitized by Google

at the centre. The particulars of the different members were then given in detail. The ordinary distance from centre to centre of the trusses was 33ft. 6in., being the same as the distance between the centres of the piers of the substructure. In crossing Upper Thames-street, however, the distance apart was increased to 35ft. 1½in., in order to suit the abutments of the bridge over that street. The weight of a single truss was 47¼ tons. The parts of the roof not glazed were covered partly with zinc and partly with slating. A lantern, 22ft. wide, extending nearly the whole length of the roof was glazed on the top, and had the sides fitted with louvres, which afforded means of ventilation. Two movable timber stages, designed by Mr. J. Phillips (Assoc. Inst. C.E.), were used in the erection of the roof. One was as high as the top of the segmental ribs, and was employed in the erection of the trusses; the other was smaller, being low enough to pass under the tie-bar, and was used for painting, glazing, and finishing. The cost of the roof of the Cannon-street Station had amounted to £49 10s. per square of 100 superficial feet of area covered, measured between the walls. The cost of the roof of the Charing Cross Station was £39 per square. In both instances the price of iron was high, the contract price for wrought iron in place in the roof being £24 5s. per ton.

The booking offices, waiting rooms, refreshment rooms, &c., were at the north end, at right angles to the lines of way, and were chiefly situated on the ground floor of the building which, above and below them, formed the City Terminus Hotel. The parcels offices, stores, cellarage, &c., were in the basement of the station, access from the rail level being given by means of stairs; while hydraulic lifts were provided for raising and lowering the parcel trollies. There were nine lines of way in the station, of which eight lines were alongside platforms, one line being set apart for spare stock and standing room. The eastern and western platforms were each 13½ft. wide at the centre, the general departure platform was 19ft. wide, and the general arrival platforms were 12½ft. wide opposite the cab road, and about 30ft. wide beyond. The principle of having a line of railway on each side of the platform, instead of a platform on each side of a line, was believed to be the most economical in space, and, relative to the space occupied, the most economical in working. The area of the platforms which were alongside trains was 43,877 superficial feet, and the length of the trains accommodated was 4,778 lineal feet, giving about 9 superficial feet of platform for each lineal foot of train.

The station-yard and signals were then described; and it was stated that the arrangement adopted was, that every line should approach every platform without back-shunting, excepting only the platform on the western side, which was to a great extent devoted to the short traffic to and from Charing Cross. This principle had been carried out by means of about forty pairs of points. The signal-box was 42ft. long by 9ft. wide; there were four posts, with twenty-four semaphore arms, eight arms being for "out" trains, and sixteen for "in" trains. The signal-box contained sixty-seven levers, of which thirty-seven worked signals, and thirty worked points. The signals locked the points and each other, so that no contradictory signals could be given; nor could the permission for ingress to or egress from any platform be given, until the points were arranged in accordance with the signal for that particular platform. An idea of the duty performed by this apparatus, which was erected by Messrs. Saxby and Farmer, might be formed from the fact, that seven hundred and seventy-five trains have passed under the signal bridge in a single working day. One morning, lately, thirty-five trains were signalled and passed in or out of the station in thirty-five minutes. Mr. Walker's electric telegraph apparatus, which worked a miniature semaphore distance-signal in each box, was used for signalling the trains on the block system.

The cost of the works of the City Terminus Extension was £505,336, and of the whole Charing Cross Railway, including the extension, £1,160,118, or including land, somewhat more than three millions sterling. In this sum, it was to be remembered, were included about 4½ miles of railway for a double line, two large bridges over the Thames, a considerable number of expensive street bridges, and two of the most extensive metropolitan termini. The importance of the traffic, which was not at present fully developed, might be gathered from the fact that, during the year ending January 1, 1868, being the first year since the City Terminus Extension Railway was opened, about eight million passengers used the Cannon-street Station, of which number about three million and a-half were local passengers between Cannon-street and Charing Cross. At the present time about twenty-six thousand passengers used the Cannon-street Station daily, and the South Eastern Railway now conveyed about fifteen million passengers annually.

RAILWAY BRIDGE AT ST. LOUIS.

SOME particulars of the Railway Bridge at St. Louis are afforded by a correspondent of the "New York Tribune." He states that the bridge will cross the Mississippi from near the foot of Washington Avenue to the dyke on the Illinois shore. The breadth and central position of Washington Avenue, the narrowness of the river at this point, and height of the banks, give this locality the highest advantage of situation. The distance between the extreme piers will be 1,584ft., but the length of the bridge, including the stone approaches, will be about 3,700ft. The bridge will cross the river on three arches. The central span will be 515ft. between abutments, and the other two 497ft. each. The piers will rest upon the solid rock which underlies the bed of the river. No other foundation would be secure against the action of the currents. Of the two central piers, one will be 170ft. high, and the other 195ft. At the base the piers will be about 100ft. by 50ft.; at the spring of the arches, 87¼ft. by 37¼ft.; and at the top, 75ft. by 25ft. The piers will be faced with Eastern granite. The erection of these piers will be a vast and arduous work. To construct immense coffer-dams in the middle of a rapid and powerful stream, to excavate the earth at the bed of the river to the depth of 60ft. or 80ft., and to build towers of solid masonry nearly 200ft. high, will test the utmost resources of modern engineering. The stone for the construction of the piers will be procured from the quarries at Grafton, Illinois. These quarries lie on the bank of the Mississippi, forty miles above St. Louis. A contract has been made for about 200,000 tons of stone. The material is a compact and durable limestone. The superstructure will be supported by ribbed arches of cast steel. Each span will be composed of four arches, placed side by side with a lateral interval of 12 ft. between the arches. Each arch will consist of two steel ribs, one above the other, with a vertical distance of 7ft. between them. Both arches and ribs will be strengthened with diagonal brackets of wrought iron and crucible cast steel. The height from the spring line to the crown of the central arch will be 51½ft., and the height of the other two arches will be 47 5-6ft. The width of the superstructure will be 52ft., from railing to railing 50ft. On each side of the bridge there will be a raised footway 7ft. wide. A Nicholson pavement, 36ft. in width, will afford ample room for cariages, and a double track for street cars will furnish passengers with additional facilities for crossing.

The railway bridge will be directly underneath the carriage way. Its distance from the upper works, to which it will be attached, will be 16ft. Two double tracks, each having a double gauge of 6ft. and 4ft. 8½in., will accommodate all the railways that converge at this point. The weight of the bridge will be three tons per lineal foot, and its capacity of sustaining burdens four tons per foot. The bridge will be 50ft. above high water; but at the ordinary stage of the river it will be from 60ft. to 75ft. above the water. The City Directrix very nearly corresponds with the curbstone at the corner of the Levee and Market-street. In 1844, the river rose 7·58ft. above the Directrix, and in 1863 it fell 33·81ft. below the Directrix. This is the extreme range of high and low water. The ordinary difference of level is less than one-half of this amount. The bridge will cross each Levee on five stone arches, each having a span of 28ft. On each side of the river there will be at the outward end of the stone-work a spacious and elegant toll-house, containing the offices of the company. On the west side of the bridge the railway will enter a tunnel at Third-street, extend under Washington Avenue as far as Ninth-street, then curving broadly to Olive-street, pass along under Eleventh-street till it emerges in the bed of the old Chouteau Pond. On this spot it is proposed to erect a grand central station for all the railways that intersect or terminate at this point. The average height of the tunnel will be 20ft., its width 24ft. and its length about 5,000ft. The mean depth of the tunnel below the surface will be about 25ft., and the height of the base above the Directrix 33ft. Two tracks of rails will be laid in the tunnel. The estimated cost of the bridge and its approaches, including incidental expenses, is:—

	Dollars.
Arches	1,665,039.00
Piers and abutments	1,387,163.60
Approaches	457,568.00
Tunnel	668,292.00
Land damages	705,736.00
Ten per cent. for contingencies	488,439.86
Total	5,372,838.86

These were the original estimates. Later changes in the plan of the structure will probably reduce the aggregate to 5,000,000 dollars. The officers of the St. Louis and Illinois Bridge Company are:—Charles K. Dickson, President; Barton Bates, Vice President; James B. Eads, Chief Engineer; John A. Dillon, Secretary. Board of Directors—Charles K. Dickson, James B. Eads, Wm. Taussig, Thomas A. Scott, Amos Cotting, Barton Bates, Josiah Fogg, John R. Lionberger.

The company act under special charters granted by the States of Missouri and Illinois. Their franchises are liberal and ample. The members of the company are men of character and wealth. They are in earnest in this undertaking. They mean to push it forward to an early consummation. The time allotted for completion of the bridge is three years. The initial labour is already begun. The coffer-dam for the western pier is finished, and the excavations for the foundation are far advanced. New York, Philadelphia and Baltimore are deeply interested in the success of this undertaking. The great trunk lines of travel will cross the continent on the parallel of St. Louis. Economy of time is the supreme demand of commerce. The shortest distance and the least obstruction are the conditions which will determine the route of the highway to the Pacific. A straight line from Philadelphia to San Francisco passes very near St. Louis. In the mild climate of this southern latitude, the snow which barricades the northern routes will oppose no serious obstacle. The constantly increasing, and almost insuperable difficulties which would attend such an undertaking at any point lower on the river, render it extremely probable that no bridge will ever cross the Mississippi below St. Louis. Hence the great cities of the Atlantic frontier should be virtually interested in the erection of a bridge which, lying virtually upon their own parallel, and at the lowest available point on the Mississippi, will afford them the most direct, least obstructed, and only unbroken southern route to the Pacific.

IMPROVEMENT IN NAUTICAL COMPASSES.

THE prevention of oscillation in compasses and magnetic needles on board ship in heavy seas forms the subject of a patent lately taken out by M. Pierre Laurent, of St. Nazaire, late of the Imperial Marine. His invention can also be applied to render magnetic needles or compass cards more sensitive when sluggish. That which characterizes the present invention, and distinguishes it from all others having the same object, is that the stability of magnetic needles and compass cards is obtained by loading them with weights placed as far as possible from the point of suspension, and that, on the other hand, more sensitiveness is obtained by loading the compass cards or needles with weights as near the centre as possible. Carrying out this principle, M. Laurent has devised the following methods. To give more stability to compass cards, or magnetic needles, he diminishes as much as possible the weight at the part adjoining the point of suspension, either by thinning the needles at this part, or by changing their form by making the cap lighter, and diminishing the weight of the central part of the compass card, or by suppressing this central part, and increasing the weight near the circumference by giving to the extremities of the needle or needles an enlarged form, and, if necessary, by adding near the extremity of the needles an additional weight, such as a piece of metal, or a ring of metal on which the card is fastened. To render the needles or cards more sensitive, M. Laurent diminishes as much as possible the weight at the parts most distant from the point of suspension by thinning the needles at their extremities, and increases the weight near the point of suspension by enlarging the needles at this part by increasing the weight of the cap, and, if necessary, by the addition of pieces of metal.

The foregoing are the principal modes by which compass cards or magnetic needles are rendered more sensitive, or more steady, but for rendering steady a needle, or a set of needles, or a compass card already constructed, the following methods are adopted:—Suppose, for example, that it is required to render a compass card, or a set of magnetic bars or needles more steady, weights are placed on opposite sides of and as far as possible from the point of suspension, care being taken to place the weights equally, so as to maintain the horizontal position. The heavier these weights (which are termed inertia weights), the more steady will be the card or needle; the farther these inertia weights are placed from the point of suspension the greater the stability, from which it follows that the degree of stability of the cards and needles is regulated according to the requirements of the weather and the sea. When, on the contrary, the inactivity or sluggishness of the compass card or needles necessitates an increase of sensitiveness, it is obtained by weighting the card or needles as near as possible to the point of suspension. Thus, to increase the stability of a compass card, or a magnetic needle, or a set of magnetic needles, they are weighted as far as possible from the point of suspension to increase the momentum of inertia, while, for increasing their sensitiveness, they are weighted as near as possible to the point of suspen-

Digitized by Google

sion to diminish the momentum of inertia. The weights are of a form to suit the arrangements of the instrument, and they are made of any substance which does not possess magnetic properties to influence the compass card or needle.

A NEW ANÆSTHETIC.

SCIENCE, like history, seems to revolve in circles. The fertile idea of efficient anæsthesia in surgical operations, which has been so pregnant with blessings to mankind, was thrown out by Sir Humphrey Davy in experimenting with protoxide of nitrogen—laughing gas. The American dentist, Wells, actually applied it in practice without encouraging success; his partner, Morton, pursuing the research, was led to the use of sulphuric ether, and became, in fact, the great discoverer of practical anæsthesia, and the benefactor of his race. The desision adverse to the use of protoxide of nitrogen gas seems, at least, to have been hasty, for the "British Medical Journal" states that Dr. Thomas W. Evans, of Paris, has just given a series of demonstrations of its use at the Dental Hospital of London, and at the Central London Ophthalmic Hospital, to crowded circles of dentists and surgeons, and has produced results hitherto unknown here. Given by his and Colton's method, the period required to produce unconsciousness has been less than 45sec.; the operations have been harmless, the sensations of the patient agreeable, and there has been no struggling or distress. The recovery has been almost instantaneous, and without headache, giddiness, sickness, or prostration, such as so frequently followed chloroform. In fact, in many instances, three minutes after the patient has expressed a willingness to submit to operation he has been standing chatting gaily by the chair, the tooth having meantime been painlessly extracted, and he having passed through a period of total unconsciousness without any disagreeable sensations. But it has yet to be shown how far the unconsciousness can be protracted, as is necessary for prolonged surgical operations. And great caution must be enjoined in using this agent, even by Dr. Evans's method, until we have more of our own experience to guide us. But taken with all qualifications, the results are very surprising, deeply interesting, and of great promise as supplying that important desideratum—a painless and rapid anæsthetic suited for those who have to pass under the hands of the dentist, and for the quicker operations of surgery, and of which the effects are entirely transient.

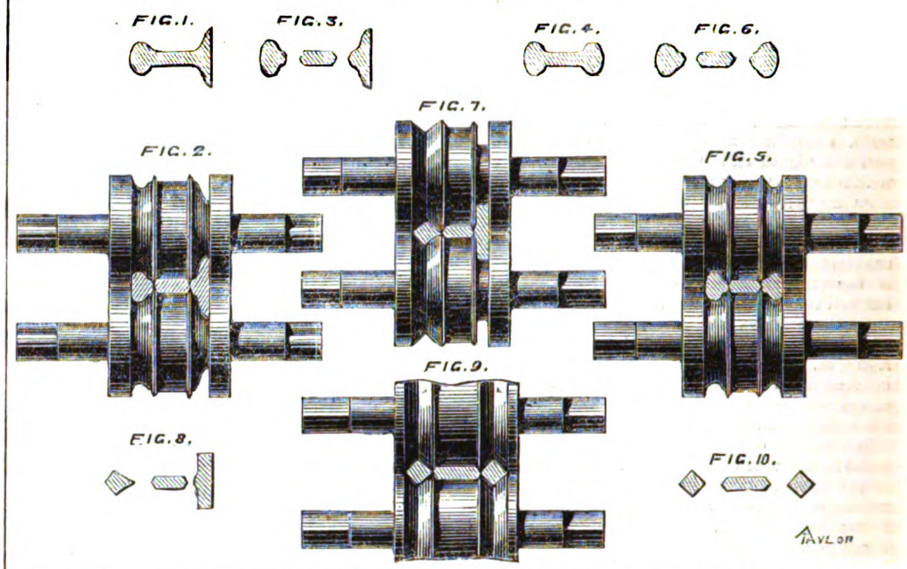
THE LIME LIGHT.

THE arrangements for supplying Perth Barracks with the lime light are being rapidly proceeded with, and before long we hope to see it demonstrated there that this beautiful illumination is as applicable on private buildings, and in a small way, as it has hitherto proved to be on an extended scale. Its principle is exactly the same as that known as the "Drummond light," but some slight improvements have recently been introduced into its working. Three substances are concerned in the production of the light—viz., two gases, oxygen and hydrogen, and a solid—lime. The "London Scotsman" states the mode in which these are used to be as follows:—A jet of hydrogen being lighted, a jet of oxygen is turned on so as to mix with it, and the solid incombustible lime being so arranged as to be exposed to the intense heat, it emits a light so pure and so powerful, that it is only rivalled by that of the sun. The method of using and lighting the jet is precisely the same as with a common gas burner; so that no special knowledge or instruction is requisite for its management. Where the consumption of the lime light gases does not exceed 1½ft. per hour, the light produced is equal to four gaslights, each burning 5ft. per hour. Three feet per hour give a light equal to fifteen gaslights, each burning 5ft. per hour. Six feet per hour give a light equal to sixty gaslights, so that 6ft. are equal to 300ft. of gas. The two gases may be easily produced, and a very small main would be sufficient to convey them through the streets for the lighting of dwelling-houses, a purpose for which this light is singularly well fitted, as its products of combustion are quite innoxious, and have no tarnishing effects. Another advantage is, that it exercises no changing influence on colours, every tint being as distinctly observable by its assistance as in the light of the sun. Various towns in Scotland are adopting the light, and if, as will doubtless be the case, the experiment at Perth proves satisfactory, it is expected that the lime light will gradually supersede the use of gas.

THE Newspaper Press Fund dinner will take place this year on Saturday, the 6th of June, at Willis's Rooms, under the presidency of the Duke of Cambridge, and the arrangements which are being made by the committee for the occasion lead to the belief that the forthcoming festival will present as great an attraction and prove as successful as any of the previous anniversaries.

MACHINE FOR CUTTING UP RAILS.

BY MESSRS. MARTIN AND DYSON.



MACHINE FOR UTILIZING BESSEMER STEEL RAIL ENDS.

THE question has often being asked, what is to be done with all the Bessemer steel rail ends. This has never been satisfactorily answered, but many attempts have been made to work them up, such as cutting the flange rail end up for scrap entirely or cutting the top off with ordinary shears, rolling it into rods or wire, and leaving the remaining two-thirds for scrap, or cutting the projecting flange off level with the head and then rolling it in the ordinary way into rods, or perhaps more generally into sheets, the same as double-headed rail ends are done. But there has always been great difficulty attached to these methods, and they have failed to produce good rods without an enormous amount of waste. We have, however, to notice a patent which has just been granted to Messrs. S. Martin, jun., and Company, of Sheffield, in conjunction with the Messrs. Dyson, also of Sheffield, by which the above expensive and objectionable processes are dispensed with. In the new plan, either a flanged or a double headed rail or rail end is cut by circular cutters longitudinally at two given points, viz., at each side of the web, and thus three bars are obtained composed of the head, the web, and the flange bottom or the second head. Each of these pieces can be rolled at the same time that they are cut into pieces, bars, or rods by any ordinary machinery. By the above method it will be seen that a great saving is effected in the amount of scrap made, because it often happens that a rail end is unsound on one side only, and by the old process the whole would have to be cut up into scrap, but by this patent it will be seen that this defect would only render one-third of the rail end useless, inasmuch as a good head and web would be obtained from it.

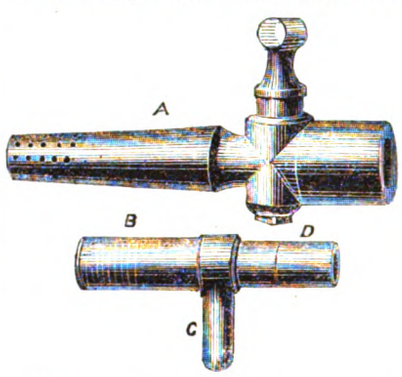
The circular cutters can be made from chilled metal and turned up to the desired shape, as shown in our engraving, or they may be formed by wrought-iron shafts with collars and steel cutters bolted thereto, and regulated by markers to suit any section of rail ends. A large quantity of rail ends have already been used up by this process with very satisfactory results, inasmuch as the patentees declare that a saving of at least 25s. per ton is effected over and above the old processes, and we need not remind our readers that in these times of competition this is a consideration.

In our engraving, fig. 1 represents a single-headed or flat-bottomed rail, and fig. 2 represents the same after if has been cut by the cutters shown in fig. 3. Fig. 4 represents a double-headed rail, and fig. 5 represents the same after it has been cut by the cutters shown in fig. 6. In some cases the cutters or rolls are made of such form that they roll the head or the bottom, or both the head and the bottom, into square and flat bars at the same time that they slit or cut the rails. Fig. 7 represents a pair of rolls or cutters which will cut and roll the single-headed rail shown in fig. 1 into the form represented in fig. 8; and fig. 9 represents a pair of rolls or cutters which will cut and roll the double-headed rail shown in fig. 4 into the form represented in fig. 10. The cutters or rollers are, of course, driven by any convenient arrangement.

A GENERAL meeting of the members of the British Horological Institute, for the election of a trustee, in place of the late Mr. Valentine Knight, will be held on the 21st inst., at the Institute, 35, Northampton-square, E.C., at 8.30 p.m.

SELF-ADJUSTING TAPPING COCK.

THE ordinary method of connecting the pipe leading to the beer engine with the newly-tapped barrel is by means of a screwed collar and washer. Publicans well know this to be a very inefficient joint, occupying time to make, and often being attended with leakage. We are, however, glad to tell them that a very simple remedy has been devised by Mr. B. Haynes, of No. 90, Broadwall, Blackfriars. This invention, which Mr. Haynes has patented, consists in the self-adjusting tapping cock shown in our engraving. In this apparatus Mr. Haynes takes advantage of the cohesion of two closely-fitting surfaces. The cock is made in two parts, A and B. The part A is, of course, tapped into the cask, the part B is then placed in the mouth of the cock,



in which it is instantly fixed by a smart blow from a hammer on the stud C, which is cast with it. The inner surface of the mouth of the cock A being carefully bored, and the outer surface of the piece B being turned, an accurate fit is obtained, and no pulling force will part them when once set. A tap from the hammer, however, immediately separates them, and the pipe, which is soldered on at D, is readily transferred to another cask. Mr. Haynes has had this tap in use for some time, and it proves a great success. In fact, it is such a decided improvement upon the old method of tapping, that we cannot expect otherwise than that it will come into general use.

THE fifth exhibition of the Society of the Friends of Art, of Pau, is now open, and will remain so until the 27th of April. Considering the remoteness of this fashionable resort in the Pyrenees, the number of works exhibited is very large, namely:—361 pictures and drawings, and twenty-one pieces of sculpture, the latter including a charming statuette, entitled "Concordia," and a bust of Richard Cobden, by a well-known sculptor, M. Megret. Twenty-two works have already been purchased by amateurs, but the selections of the Society itself are not yet made; the Museum of Pau and the English Club there are also expected to be purchasers. Altogether, this exhibition promises excellent results.

SOCIETY OF ENGINEERS.

AT a meeting of the Society of Engineers, held April 6, Mr. Baldwin Latham, president, in the chair, the following practical paper on the Redhill sewerage works, was read by Mr. Sydney A. Reade, M.A., C.E.

These works were designed and carried out by Mr. Baldwin Latham, C.E., president of the Society of Engineers, for the Town Council of the borough of Reigate, the author being appointed by Mr. Latham as resident engineer of the works. The first contract for the works has just been completed by Mr. Joseph Brown, of Croydon, under the author's supervision; and it is now proposed to bring before the notice of the Society of Engineers the general character of these works, as regards both their design and execution, in the hope that, as the subject of sanitary engineering has been this year presented for their consideration by the president of the Society in his inaugural address, a brief and plain account of what may be called a particular case of this branch of the profession may not prove uninteresting to some of the members; he will also venture to make such general remarks on the subject as seem to him to arise out of this particular case.

The town of Redhill, in the county of Surrey, is about twenty miles south of London, and must be well known to all travellers on the Brighton and South-Eastern Railways, it being the junction of these two main lines together with the branch of the South Eastern, which runs westward to Reading; it forms part of the foreign of Reigate, and is governed by the mayor and corporation of that borough, who, having adopted the Local Government Act a few years ago, soon turned their attention to the sanitary improvement of this rapidly increasing village, and took measures to provide for its complete main drainage, and a profitable disposal of its sewage. The town is situated at the junction of two valley lines at right angles to each other, one running (approximately) north and south, the other east and west. A stream runs through the former, falling southward at the rate of about 8ft. to 10ft. per mile, and as the latter rises considerably westward, the surface drainage of that part of the town has a rapid fall towards the stream, which sometimes occasions the flooding of a large area on each side during the winter months.

The geological strata of the whole of the drainage area included in the present scheme belongs to the lower green-sand formation, underlying, however, in the river valley a deposit of peat of variable thickness, reaching in some places to a depth of 15ft. and upwards; this, as may be imagined, forms a perfect quagmire in wet seasons, and even at the driest time of the year is in a state of complete saturation at a small depth from the surface. About seventeen or eighteen years ago the road from London to Brighton was carried through this bog, the foundation being formed of faggots and brushwood, and the portion of this road nearest to the railway station was chosen as the "high street" of the future town, without regard being paid to the probable difficulties of drainage, health of the inhabitants, or even stability of the houses, which are all built on the surface, in most cases, without any kind of foundation, the town hall excepted, which is built on piles. Such being the position of the town the course that must necessarily be taken by the outfall sewer, which is to effect its drainage, is obviously determined by the direction of this lower valley line. It is kept nearly parallel to the stream, and empties itself into it at the temporary outfall, which will hereafter be abolished and the main sewer carried on to the proposed irrigation fields. This land forms part of Earlswood Common, and is situated about $1\frac{3}{4}$ mile south of the town, and at a level sufficiently low to allow a fall of about 1 in 600 to be given to the outfall sewer. The area over which it is proposed to send the sewage contains sixty-three acres, and the area of supply contains about 500 acres, on which there are now but 750 houses, and a population of 4,500. As this would only be seventy-one individuals for each acre of irrigation land it is probable the whole of the sixty-three acres will not be laid down at first, but the area gradually extended as the population increases.

The Lord of the Manor (Earl Somers) has agreed, with the consent of the copyholders, to give up this part of the common to the Board of Health gratis, on the condition of their purchasing sixteen acres of land on a higher level, to be kept as a recreation ground for the inhabitants of Redhill: the Corporation have arranged to purchase this land for the sum of £4,000. They will thus obtain seventy-nine acres for that sum, or at the rate of £50 per acre, which is less than 1-6th of the value of average land in the neighbourhood. The common at the surface is stiff clay, not more than from 4ft. to 8ft. deep, overlying the sand before alluded to, but not containing any admixture of sand; part of this clay is used for brickmaking, and the author found the bricks produced from it of very superior quality. The south side of this ground slopes gently towards the south, the north side is nearly flat; it will probably be laid down for irrigation on both pane and gutter and bed systems; and from its favourable position, open towards the south, and sheltered by the hills on the north, the author would anticipate heavier and more frequent crops of rye grass than are now obtained at South Norwood, where the soil is very similar. The first great requisite for the successful prosecution of sanitary improvements having thus been fortunately obtained, the next thing to be considered was the size of the outfall sewer; this, of course, is determined by 1st, the maximum quantity of fluid matter it is designed to take; 2nd, by the maximum inclination it is possible to give it. As regards the former it is not the author's intention to go into any minute calculations respecting the probable amount of rain falling on this drainage area per annum; what amount of it will find its way to the sewer; how long it takes to do so; what proportion will fall in streets, roofs, and back premises, and thence to arrive at the dimensions of the outfall sewer. It would, no doubt, be an easy matter to take some of the published tables, and run the finger down the columns for the figures answering to Redhill, its area, population, &c.; but conclusions based on this sort of arithmetic are as likely to be wrong as right. To use Mr. Rawlinson's words, "You may as well say that all sorts of diseases may be cured with one set or sort of pills, as that tables of strength of materials and dimensions of sewers can be relied upon without the experience of practice." In answer to questions of this kind, he gives a list of towns drained by him, with their population, area, &c., and the dimensions of the outfall sewers in each case, and the author would add Redhill to the list of practical examples, which, after all, are the best guides in assisting the judgment of young engineers. It will, however, be generally admitted, that in towns where the existing sewers are sufficient to take off the greater part of the rainfall, they need not be interfered with; but the new sewerage is designed to take all foul matter and a certain proportion of the rainfall. With this end in view the outfall sewer at Redhill is designed. It is egg-shaped, 3ft. 9in. × 2ft. 8in., sectional area 7·64 square feet, perimeter 10·12ft., a hydraulic mean depth, therefore, when running full of 0·755ft.; its capacity of discharge under these conditions would be about 1,400 cubic feet per minute.

It should be mentioned that the outfall sewer at present receives a small supply of water from the deep-seated springs in the sand. This amount the author has carefully measured, and finds to be thirty cubic feet per minute, and not perceptibly affected by the amount of rainfall at different times. Adding to this the average flow of a small brook which has been diverted from the roadside into the sewer, and which may be taken at fifty cubic feet per minute, and the probable maximum flow of sewage from the present population at 31·25 cubic feet per minute, we have a total of 111·25; to which may be added 1,000 cubic feet for the proportion of the maximum rainfall that will reach the sewer; leaving a margin for the extension of the population, which there is good reason for supposing will double its numbers in the next ten years. It is probable, also, that many of the shallow drains, which at present needed not to be interfered with, will, as houses multiply, necessarily be abolished, and the refuse water they now convey away be brought into the sewer.

Before leaving the subject of the dimensions of egg-shaped sewers, the author asks permission to submit to the notice of the members three general formulæ applicable to the construction of egg-shaped sewers, which he deduced for his own convenience in calculating the area and perimeters of the Redhill sewers and in constructing the templates for the bricklayers. These sewers deviate somewhat from the usual proportions, which are as follows:—B = equal diameter of circle forming invert; C = diameter of arch; R = radius of curve forming sides; D = depth; then B = $\frac{1}{3}$ D; C = $\frac{2}{3}$ D; and R = D. These are the proportions taken from Molesworth, and are those for which tables of areas, hydraulic mean depth, &c., have been constructed. They certainly offer great facilities to the draughtsman; but it will readily be admitted that circumstances may arise where a sewer having a greater proportional width to its depth than is given by this construction, may be desirable; for instance, the engineer, from the proximity of the surface of a road to the crown of his arch, or from other causes, may wish to reduce the depth of his sewer while still preserving the same sectional area, and retaining the advantages of the egg shape; and there is no reason why he should be compelled to use this particular form, and no other, merely because it has been the custom to do so. In the present case the main sewer was partially above ground for a considerable portion of its length, and it was desirable to reduce the mound in the field through which it passed as much as possible. Now, it is easily seen that if the proportion of B and C to D are altered, and also the proportion they bear to each other (as given above), R is no longer equal to D, and the two circles do not touch, the distance between their centres being no longer equal to the sum of their radii. It thus becomes necessary to furnish the draughtsman with a new value for R which shall be perfectly general in its application. This expression and the other two for the area and perimeter will be as follows:—

R being the radius of the side, r of the arch, and r_1 of the invert, and d the distance between the centres of the circles, obviously equal to D—$(r + r_1)$, we shall have

$$(1.)\ R = \frac{1}{2}\left(\frac{d^2}{r - r_1} + r + r_1\right)$$

$$(2.)\ A = \frac{\pi}{180}\left(\theta^\circ (R^2 - r_1^2) + 90\,(r^2 + r_1^2)\right) - d\,(R - r)$$

$$(3.)\ C = \frac{\pi}{90}\left(\theta\,(R - r_1) + 90\,(r + r_1)\right)$$

The above are easily deduced, and might prove useful to others, as I have found them. The angle θ deg. which is that subtended by the arc forming the sides, may be found from from its sine, or tan., for

$$\text{Sin. } \theta = \frac{d}{R - r}, \quad \text{tan. } \theta = \frac{d}{R - r_1}.$$

Up to the present only 220yds. of the outfall sewer have been constructed, and a temporary outfall formed into the brook. As there was some delay in obtaining the necessary borrowing powers from Government for the purchase of the land, the corporation thought it undesirable to postpone the construction of the sewers till that was obtained. Now, however, that the land question has been satisfactorily settled, and the greater part of the drainage scheme completed, there is no further hindrance to the continuation of the outfall sewer to the proposed irrigation fields. The bricks for the sewer were specified to be radiating, and at first the author had them made of two different forms, one to suit the exact mean radius of the arch, and another for the invert. This, however, was found to cause a delay at the brick-yards, and caused the author to substitute a mean brick, which answered all curves of the different sewers without making the outer joints objectionably wide. The inverts were cast in blocks in the usual way, and were allowed a week to set before being inserted in the work. The curve forming the sides of the sewers was built with ordinary-shaped bricks, the radius being large enough to allow this to be done. The thickness of the brickwork was 9in., and the compost composed of two parts sand to one of Portland cement, which was specified to be of such quality as to bear a tensile strain of 180lb. on the square inch, after seven days' immersion in water. Specimens were tested, from time to time, and answered the required test. In cases where rapidity of setting is important, it is, no doubt, of value, but to prove the actual strength of the cement when thoroughly set—*i.e.*, when at its best—it seems to fail. The author has found cement taken from some casks which were supplied by Messrs. Hall and Co. for these works set hard in a few hours, whilst other specimens would take as many days. One instance out of many he selects: in casting the blocks for the 2ft. culvert in the London-road, where the ground was very bad indeed, the foreman of the bricklayers complained that one or two casks of cement were so bad that they were obliged to reject them, as the cement would not go off at all. A specimen was mixed on a board and examined; after a few days it was found to be so soft that the impression of the finger could be made on it. A portion of the same cement was inserted in the testing-frame, and allowed to remain for three weeks, and was then tested by the author and Mr. Hornibrook (borough surveyor of Reigate), and found to bear a tensile strain of 367lb. per square inch, or more than twice the required strain; and its hardness was found to be about $3\frac{1}{4}$ on Moh's scale of hardness, as it easily scratched a specimen of heavy spar; although had it been subjected to the seven day test of 180lb. it must have failed entirely to bear it.

(To be continued.)

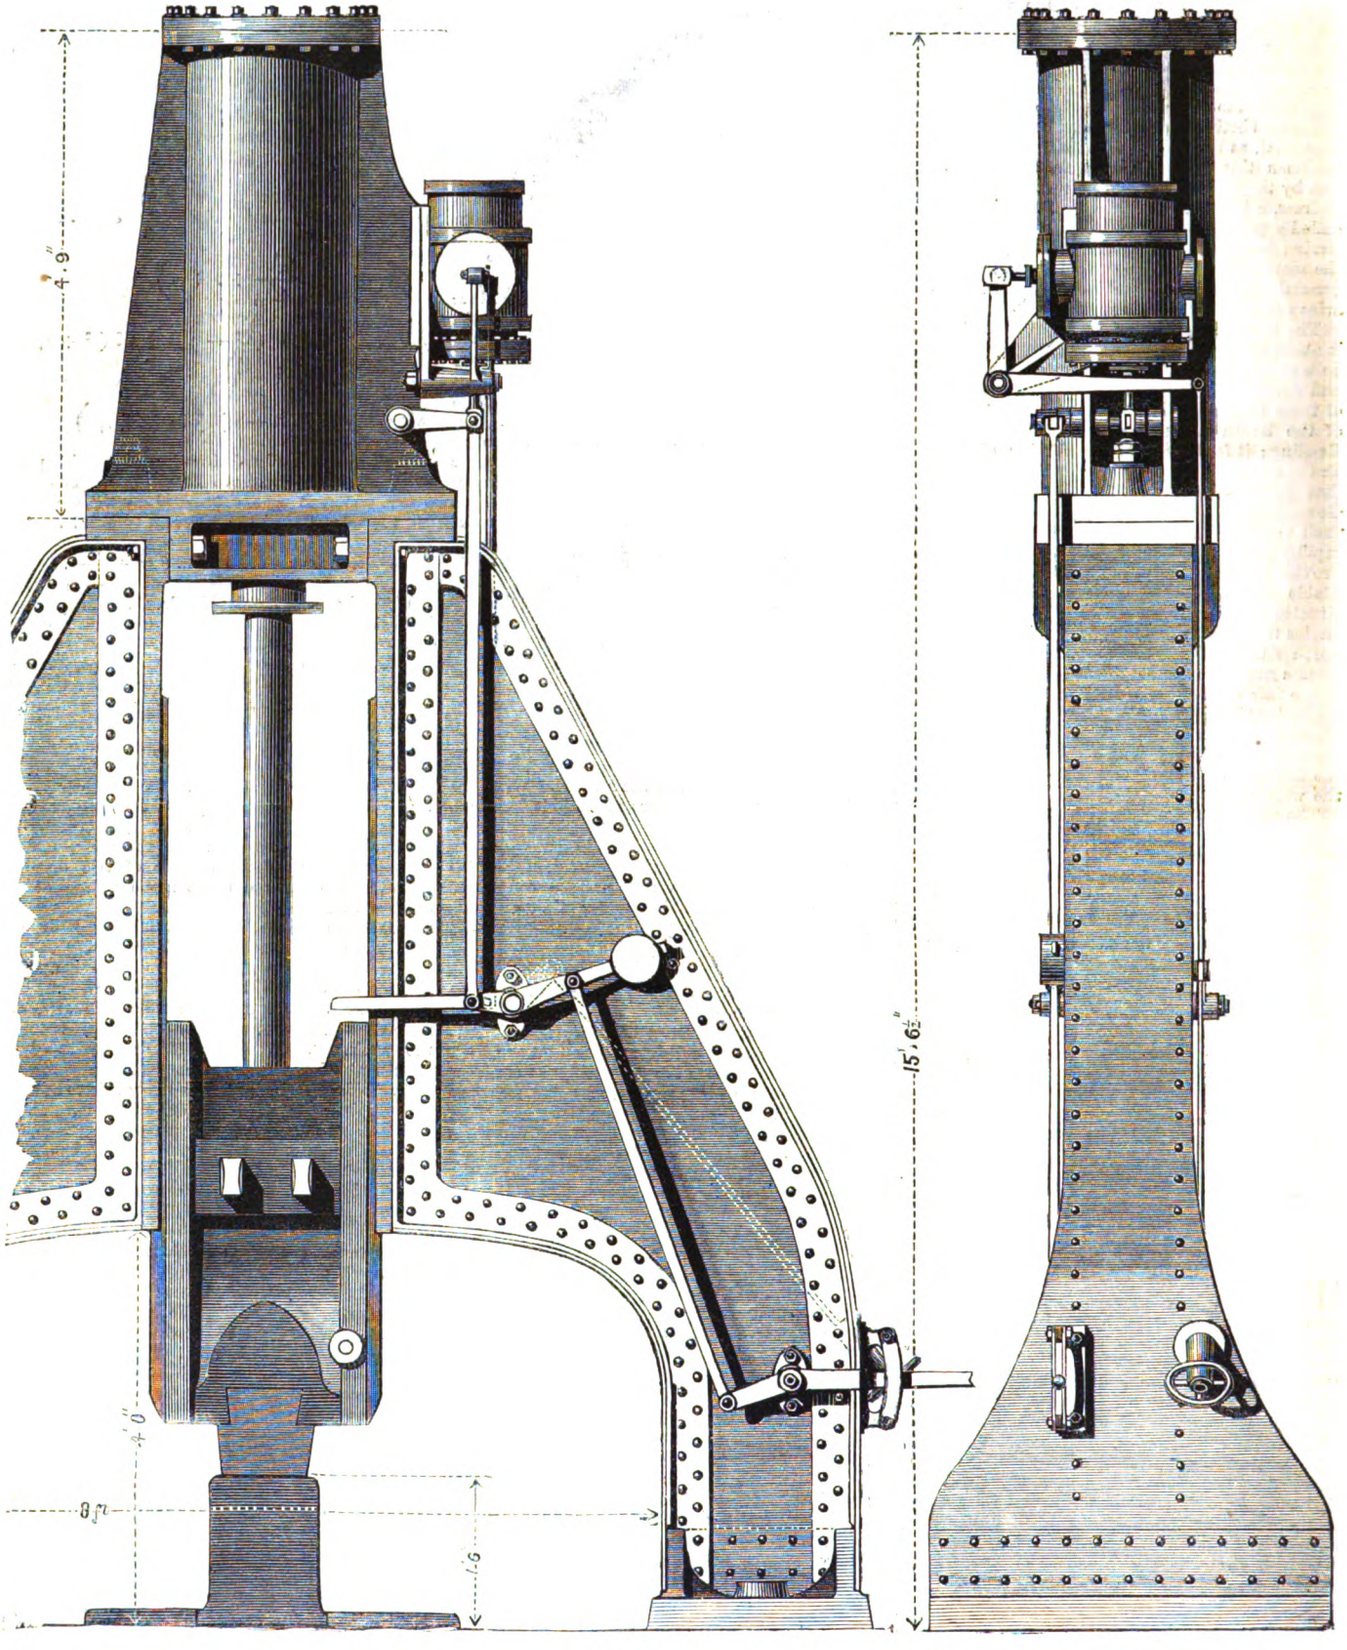
TWO-TON STEAM HAMMER.

BY MESSRS. THWAITES AND CARBUTT.



TWO-TON STEAM HAMMER.

IN the above engraving we give front and side elevations of a two-ton steam hammer, which was exhibited at Paris last year, by Messrs. Thwaites nd Carbutt, of Leeds. The form adopted in this example is at once elegant in appearance and sound in principle. The hammer has an 18in. cylinder and a stroke of 4ft. The frame is of wrought iron, and the workmanship is very superior, all the rivet-holes being bored out and the plates planed, so that the joints are nearly invisible. Wrought-iron standards have been employed before, especially in tilting steel, in which work the hammers are exposed to very severe strains. Messrs. Thwaites and Carbutt have an 18-ton hammer, very similar in construction, at work at John Brown and Co.'s, Sheffield, and the firm have made all the duplex hammers hitherto used by Mr Ramsbottom.

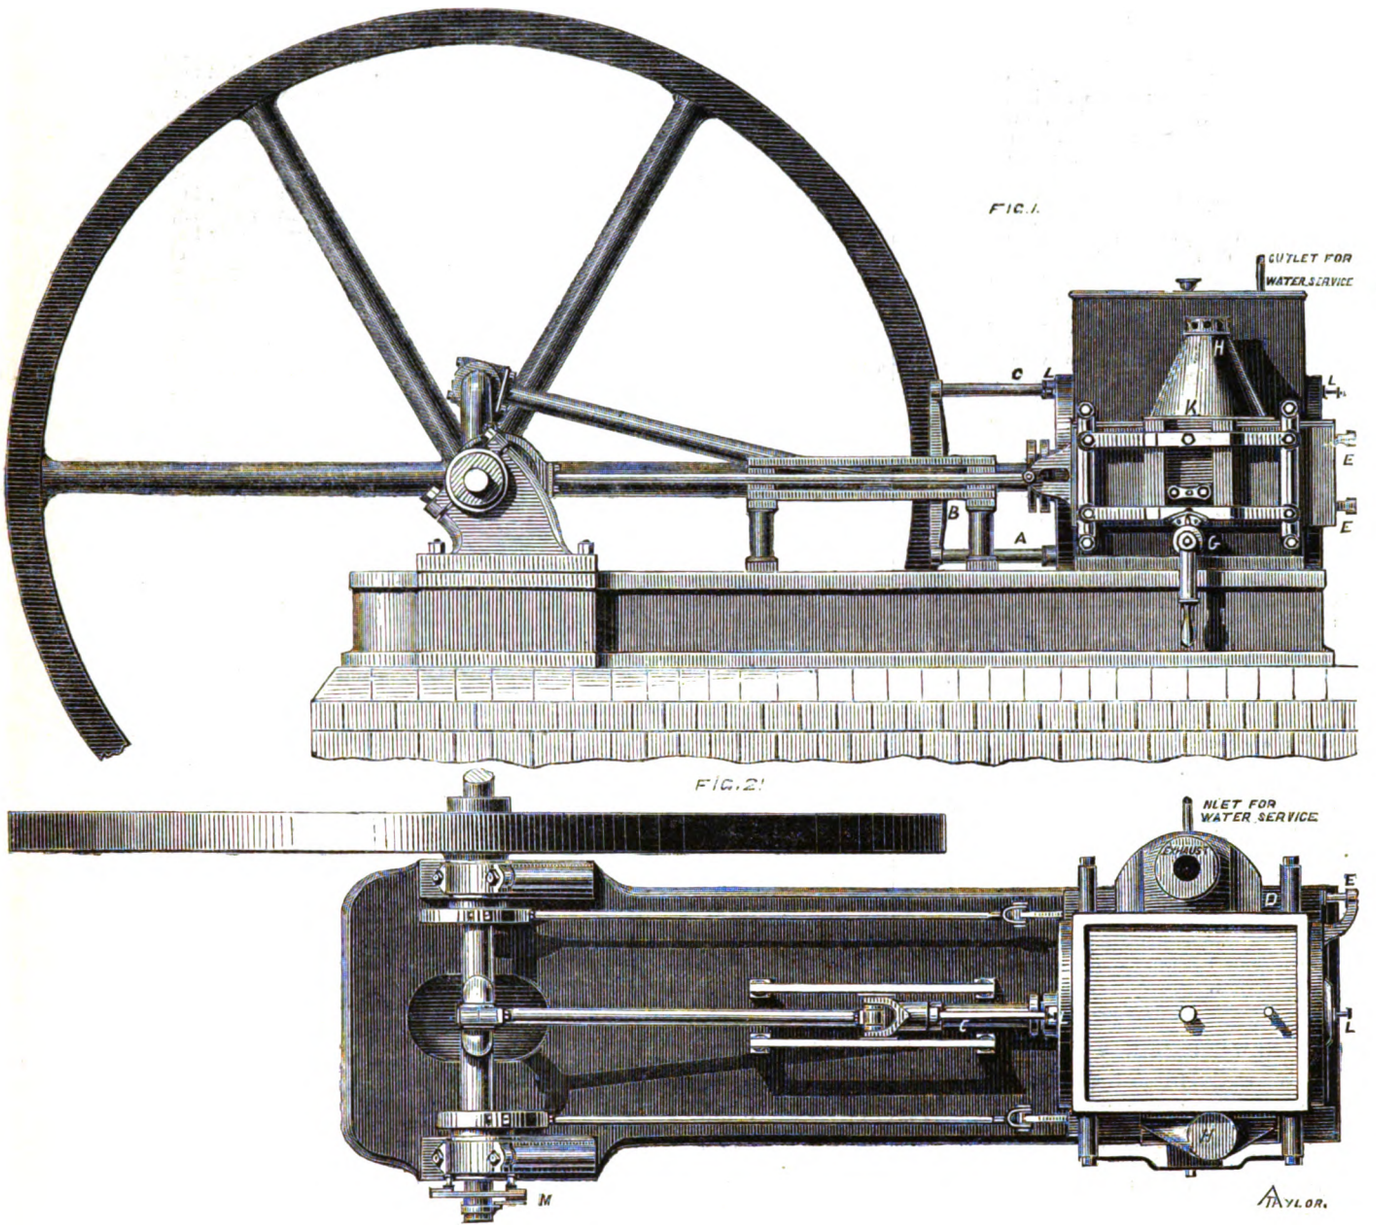
IMPROVED GAS ENGINE.

BY MESSRS. KINDER AND KINSEY.



IMPROVED GAS ENGINE.

MESSRS. KINDER AND KINSEY, engineers, of 92, Cannon-street, London, have lately patented an improved gas engine, which overcomes many of the difficulties hitherto found to operate against the successful working of these engines. This is shown in elevation at fig. 1 and in plan at fig. 2 of our engraving. It is an improvement on the Lenoir engine, which was brought out in England some seven years ago, and although many of these engines are at work and doing fairly, there has always been considerable uncertainty as to the power given off. It was found that the Lenoir engine, when freely supplied with the gas necessary to give off the power, became so intensely heated that distortion and abrasion set in, and it finally pulled up from excessive friction; this invariably happened when the engine was worked up to or beyond its nominal horse power, and hence the necessity of devising some means for getting the extra caloric quite under control. To effect this, Messrs. Kinder and Kinsey have placed the cylinder in a square closed tank, and use straight instead of the usual S-shaped passages; by this means the passages and cylinder are kept at a uniform temperature. The piston and piston rod are made hollow to allow the water to circulate through them. The piston rod is fitted with a horizontal diaphragm, which allows the water to flow from the bottom of the tank through the tube A into the crosshead B, and to the piston, returning back through the piston rod above the diaphragm, and through the tube C to the top of the tank. The tubes A and C work through stuffing boxes in the cylinder cover, and as the tube A is trumpet-shaped at the end, it gathers and forces the water through the piston and rod, and finally through the tube C, to the top of the tank. The exhaust valve D is made hollow, divided by a diaphragm, and is supplied with water by the tubes E, which work through stuffing boxes on the valve. By these means the cylinder, piston, and piston rod are kept at a uniform temperature, and no more water is required than is sufficient to make up the waste from evaporation, and the tank surrounding the cylinder is supplied with water either from a small cistern with a ball cock, or it may be made circulating from a large cistern. The lubrication required is only that of an ordinary steam engine.

The engine is worked by a mixture of air and ordinary coal gas. The gas enters at G with the force due to its pressure from the works, and is met by the air rushing in at H, in consequence of the vacuum formed by the piston. The gas and air then pass through perforations at K in the top of the valve, and thus become mixed. The mixture then enters the cylinder, when it is ignited, by means of an electric spark, from the inflamer L. The inflamers are connected by wires to the distributor M, which makes and breaks contact between either end of the cylinder and an ordinary Rumkorff induction coil, excited by a battery of two cells. There is very little trouble in keeping these batteries in order, as they only require a little fresh acid and occasional amalgamation of the zinc plates. There is an engine on this principle at the gas works, Ipswich, which works their exhauster and ammoniacal liquor pumps. It is found that an engine of 3-horse power will drive a 30in. circular saw through an 11in. deal at the rate of 8ft. per minute. The engine has been subjected to a twelve hours' test with the dynamometer, giving off 3½-horse power, with a consumption of 83ft. of gas per horse power per hour, and at the end of the trial the engine showed no symptons of flagging—in fact, increased the revolutions 50 per cent. with the same load. The Gas Engine Company (Limited) is now making and selling engines under Messrs. Kinder and Kinsey's patent, which, we understand, are giving great satisfaction.

Arrangements have been made for maintaining a direct weekly mail service between Suez and Zulla, instead of sending a steam vessel, as hitherto, to intercept the Indian mail packets off Jubbel Teer in the Red Sea; and the mails for the British forces serving in Abyssinia will, therefore, be forwarded in future to Suez, for transmission direct to Zulla. The correspondence addressed to persons serving on board transports engaged in the Abyssinian expedition, which has heretofore been sent in the mail to Aden, will in future be forwarded in the mails to the postmaster at Zulla.

THE STATISTICS OF ACCIDENT.

WE are constantly reading or hearing of accidents, and occasionally seeing them, and all of us are agreed that there must be a great number during the year. But few of us are prepared for the startling announcement that two millions of persons receive injury every year from accidents of a more or less serious character. Of these it appears that ten thousand are killed or die from the direct effects of the accident; others are maimed for life, and nearly all are disabled for a greater or less time from following their avocations. We have these facts on the authority of the Accident Insurance Company, of 7, Bank-buildings, in a statement which gives a further insight into the nature of these accidents, and in which they are enumerated and classified under different heads. Taking, then, the list of claims paid by this company, during the year 1867, we find that 54 persons have been injured by railway accidents. Of course this is only a portion of the injuries that have really resulted from railways, but it is that portion with which this company has had directly to deal, as, indeed, are all we are about to notice. Accidents at home include the thousand and one casualties with which the youngest is familiar, and of these there are 226 enumerated. Of fire accidents there are 22, and of skating accidents 6. The carriage accidents number 104, the mining accidents 13, and the field accidents 49. Street accidents form a large item, there being no fewer than 250 of these, whilst cricket accidents number 21. Business accidents are rather numerous, there being as many as 273; whilst accidents arising from the bursting and accidental discharge of guns number only 9, but one of these cost the company £500. Horse accidents toll up again; indeed, this useful animal appears to be the most prolific source of accidents, having no fewer than 470 laid to his charge. Boat and water accidents number 43; dog accidents, 8; machinery accidents, 15; and, finally, cattle accidents, 19. We thus have a total of 1,582 accidents out of the two millions for which compensation has actually been paid by one company alone to the extent of £30,000. Now, the contemplation of this subject can only lead to one conclusion, and that is, that it is a great blessing to the community that by paying a small fee per annum—ridiculously small in comparison to the advantages it secures—each member of society may get cut, bruised, or burnt, much or little, and yet suffer no pecuniary loss, although his business powers be suspended; and should the accident result in death, his relatives or representatives will be compensated for the loss of his services.

NEW RUSSIAN TURRET SHIP.

AN iron-clad frigate is about to be constructed in Russia from the designs of Admiral Popoff; she is to carry two turrets and four guns of the heaviest calibre actually in use. Her length between the perpendiculars will be 310ft.; breadth over all, 55ft.; and when fully equipped for sea, her mean draught of water 23ft. 9in., and her tonnage, 4,457 4-94 tons, builder's measurement. She will be provided with twin screw, and two sets of engines of 500 nominal horse power each. All the materials used are to be of native production, either Russian or Finnish, with the exception of a certain amount of teak and mahogany. Three years will be granted for building the frigate, which is to be armour-plated with plates 12in. thick., to be rolled at the Government works at Kolpino. Tenders were sent in by three builders, and that of Messrs. Carr and Macpherson, of the Baltic Works, for 1,295,000 roubles, was accepted. The vessel is to be built at one of the Government yards.

WE understand that arrangements are in progress for giving practical effect to the resolutions of the conference of working men, held on the 14th ult., under the auspicies of the Working Men's Club and Institute Union, and the presidency of the Earl of Lichfield. The consents of Dr. W. B. Carpenter, F.R.S., and Professor Warrington Smyth to deliver lectures, together with conditional promises of co-operation from several equally distinguished men of science, have been obtained. A sub-committee is charged with the duty of ascertaining what are the existing means of technical instruction available to working men; and steps have been taken for the representation of the artizans in the course of the inquiries to be prosecuted by Mr. Bernhard Samuelson's parliamentary select committee.

LONDON ASSOCIATION OF FOREMEN ENGINEERS.

THE members of this institution met on Saturday, the 4th inst., at the George Hotel, Aldermanbury. The chair was occupied by Mr. Joseph Newton, president, and the attendance was large. After the disposal of matters of a routine character, Mr. J. Matthias Hart, of Cheapside, and other gentlemen, were elected as honorary and ordinary members. A discussion followed as to the propriety of relaxing the rule which constitutes "a hard and fast line" against the admission of members over fifty years of age. Several gentlemen slightly beyond that period of life, but otherwise thoroughly eligible, desired admission. Their cases were finally referred to the committee.

The Chairman next took occasion to refer to the munificent conduct of Mr. Whitworth in proposing the foundation of thirty scholarships for the promotion of technical education and the study of mechanical science. The proposed use of the princely donation made by that gentleman, Mr. Newton said he considered was as admirable in conception and intention as it was important in a material sense. He sincerely hoped that the management of the fund would be effected in exact consonance with the enlightened and liberal views of its donor. It might be that some of the members of their own association had sons or other near relatives who were or would become qualified for partaking of the advantages derivable from the realization of Mr. Whitworth's grand scheme. At all events, he (the chairman) felt that foremen engineers, and especially those who, like themselves, had long since united together for mutual instruction and the cultivation of technical and practical knowledge, might hope to have their claims fairly considered. Their own association had certainly rendered good service both to employers and employed, and in presiding at its anniversary lately, and then joining it as an honorary member, Mr. Whitworth had evinced his appreciation of its value to both those classes. He trusted it would go forth to the world that the associated foremen engineers of London gladly recognized the noble conduct of Mr. Whitworth in founding the scholarships in question, and that they yielded to no section of the community in the sincerity of their gratitude to that gentleman.

A short description was then given of a new speed and distance indicator, or counter. As the apparatus itself was also exhibited, it may not be improper to state that it appeared to be in every way well adapted for its purpose—that of registering the speed of machinery, or the distance traversed by vehicles. It certainly embodies in itself several important characteristics. It is small in size, simple in construction, contains no springs, and is not costly. Mr. Hay, of 83, Lombard-street, is the agent for its introduction. The apparatus consists of a combination of several series of repeating discs. The first, cut in the form of a Maltese cross, has ten concave sides, on which are inscribed the numbering figures. The second disc has ten teeth which catch into the preceding, and the third has a single tooth on its circumference, the radius of which is equal to the concavity of the sides of the first disc. The second and the third discs are joined together, their united thickness being equal to that of the first disc. This latter is shipped on an axle at a convenient distance, so as to allow the first disc to catch in with the two others. Disc No. 1 in making one revolution carries round Nos. 2 and 3, but when disc No. 1 has checked off the ten numbering figures, No. 3, which has only one tooth, has only travelled one-tenth, or a single space on the circumference of disc No. 1 of the second series of discs, and so on. The small apparatus shown on Saturday, and which is moved by a ratchet and pawl, registers up to 999,000,000, and is easily returned to zero. Its cost was said to be about £4, the whole of the material being gun-metal. The opinions of the contrivance, as expressed by those present at the meeting, were in the highest degree favourable; and really it appeared to be equally applicable for counting with exactitude the revolutions of shafts, or of machinery of any kind—those of the wheels of locomotives or carriages, or of registering the flow of fluids, gases, &c. The apparatus could scarcely be disarranged by any ordinary casualty, and, therefore, is the more worthy of notice. The sitting of Saturday closed after a few observations from the chairman as to the preparation of an uninterrupted succession of papers and subjects of discussion for future meetings.

AERONAUTICAL SOCIETY OF GREAT BRITAIN.

AT the last meeting of the above Society the following paper on "Power in Relation to Weight in Aerial Navigation," contributed by Mr. A. Alexander, C.E., was read by Mr. Fred. W. Brearey, the honorary secretary:—

Among the comparatively few in number who believe in the ultimate accomplishment of aerial navigation, i.e., in the discovery of principles or invention of methods which will enable us not only to rise in the air, but to move at will thereon from place to place, there is observable of late years a decided, and, doubtless, a wise disposition to base calculations and endeavours more and more strictly upon the proportions and constructive details observable in nature—upon the force, form, and arrangements which, in birds, are so combined as to solve this difficult, but, as their flight seems to show, not wholly impracticable problem. These bird proportions are, of course, chiefly interesting to those who look upon them as the prototypes of aerial machines, and who have little confidence in any advantage to be derived from the use of balloons, as such methods of acquiring buoyancy, involving as they do an immense displacement of air, will necessarily involve a large amount of power in propelling them against even a very feeble aerial current. It is very important, therefore, that the real source of bird flight should be fully understood and admitted, and that the most important data consented with the wing apparatus should be determined. I observe that in the number of "All the Year Round" for 29th February last, a writer on this very interesting subject criticizes rather unfavourably the views of the Duke of Argyll and Mr. Glaisher, both members of this Society, and it was the perusal of these remarks that chiefly induced me now to forward a few further notions on this subject. The writer above referred to does not approve the doctrine that a proper relation between power and weight is all that is necessary to achieve aerial flight, and introduces, as chiefly explanatory of this fact, the theory of gas inflation in the hollow cells and vessels of the bird. This idea has been frequently stated, but, so far as I am aware, it is not supported by any facts which prove that it is more than an idea.

We have yet to learn with what curious gas the cellular spaces can be filled, possessing a levity which will afford any appreciable buoyancy. The word "gas" seems to suggest some magical sort of power in the minds of some, while, in fact, the total buoyancy derivable from the use of any gas is measured simply by the difference between its weight and that of an equal bulk of air. The air channels of all warm-blooded animals are, we know, filled with gas, which is of an average composition heavier than the surrounding air; but even if we could imagine that much absolutely vacuous space existed in the interior of the bird's body, which would be more advantageous as regards buoyancy than its occupation by any gas, however light, the elevating effect would always be of the most trifling amount in relation to that required for the bird's support. If we take the whole displacement of a bird weighing 2lb. at about 1-12th of a cubic foot, as the weight of a cubic foot of air may be assumed at ordinary temperatures = 1¼oz., it is obvious that if we could conceive the whole outward envelope of the bird's form, enclosing an absolutely vacuous space when on the wing, the additional buoyancy thus obtained would only amount to 0·104oz., or 0·3 per cent. (say ⅓ of one per cent.) of the weight of the bird. This is not only altogether inadequate, even could it be realized, but might be entirely removed without practically affecting any powers of flight; and so far as we are aware there remains no other source of the powers of aerial motion possessed by birds and insects than the amount of dynamic force in relation to their weight with which their muscular system is endowed. This appears to be the case in exactly the same sense as the power of motion of a steam vessel up a rapid current is due to the dynamic efficiency of the engines on board in relation to the midship section and displacement of the steamer. When the relation between them is sufficient, the steamer can, at the velocity depending upon that relation, successfully pursue its upward and onward course, and until that relation becomes sufficient, all attempts at upward navigation of the opposed current will be unavailing. As in the case of the supposed steamer there are two directions in which a satisfactory relation between power and resistance can be established—either by increasing the power on board by improved machinery, while the midsec-

Digitized by Google

tion and displacement of the vessel are retained unchanged, or by retaining the power constant, and reducing resistance by the employment of more suitable materials or improved methods of constructing the vessel. So we may suppose that the sufficient relation of power to weight for aerial navigation would be equally attained either by improved machinery which could develope a greater power in relation to its weight than that in use, or by the application of improved methods of construction in the flying machine. As regards the latter method, it is to be feared that there is very little prospect of surpassing the lightness, combined with strength and efficiency of the wing structure. But as this wing structure has to perform other functions than those of a mere propeller—as it is partly pervaded by muscular and nervous action—there is nothing to prevent a reasonable hope that an instrument considered merely as a propeller may be constructed as light in relation to the power transmitted through it, as even the wing of several birds. The direction, however, in which most progress is possible in establishing a satisfactory relation between force and weight lies in the improvement of any present mechanism for applying dynamic force—in reducing its weight and bulk, and increasing the tenacity of the several parts in relation to the power which can be developed.

The events of the last thirty years, the great strides which have been made in the art of transport both by sea and land in that period (accompanied as these have necessarily been by great advances in the very direction to which we now direct attention) with the greatly increased efficiency of a given weight of motive power mechanism, afford a very cheering hope that we are even now in the path which will ultimately lead, though perhaps by devious windings, to the application of force in a far more concentrated form than has yet been attained. In days not very long past, the great principles to be studied by those interested in land transport were those of MacAdam. The well-appointed stage coach, the pride of each district through which it passed, delivered its passengers and mails with something like planetary regularity, and seemed the very acme of what was possible in facilitating intercourse and disseminating intelligence. In these days it might have been said, and it was said, that it was hopeless to attempt to surpass Nature, and that it could hardly be imagined that man could ever build up any combination of mechanism to excel in results the wondrous organs already impressed into our service. Such was, in fact, a line of argument frequently pursued, and we all know that the expectations held out by those interested in steam transport were considered even by most competent and intelligent men as wholly chimerical. But the organs of living creatures owe much of their wondrous beauty and refined complexity to the performance of other functions apart from those of mere motors; and, in fact, we have, as is well known, in building machinery with only one function in view, greatly surpassed any thing of the kind to be found in the works of Nature.

In the locomotive we have a machine which not only surpasses the racehorse in speed, but has a tenacity and persistence quite beyond those of fleshy muscles and sinews. It can keep up its speed for hours together, while the horse, when urged to his utmost, cannot maintain it for more than a few minutes. But the superiority of the machine, considered merely as an instrument of transport, be it observed, is also very manifest when the ratio of weight to power is examined, and it is mainly on this account that attention is directed to the contrast as affording a hope by analogy that the same satisfactory contrast may yet be extended to other fields of progress. The power which may be exerted by a first-class locomotive at express speed is very frequently in excess of 300-horse power, *i.e.*, the pressure or tractive force applied to the train, combined with the speed of motion, are equivalent to the dynamic effect derivable from 300 horses, supposing these to work in the most favourable circumstances. As a horse at high rates of speed, such as those supposed, can exert no tractive power whatever, it is necessary to imagine an arrangement of mechanism by which the horses when moving at a few miles per hour can impart a rapid motion to the load. The weight of such a locomotive, supposing it to carry its own supply of fuel and water, will vary from 30 to 40 tons; while the weight of the horses, without taking into account the mechanism interposed between them and the load, will not be less than 180 tons. If, then, we are already so greatly ahead of natural phenomenon in one direction, there is surely nothing unreasonable in hoping that we may ultimately rival at least such natural phenomena in another direction, where the difficulties appear to be almost wholly mechanical.

As regards the actual power developed by birds in flying, further discussion is still required, and it is much to be desired that the principles upon which this is determined should be settled and adopted. I have observed in some cases, but it is very seldom one meets with any calculations on this subject, that the space through which the bird would fall during a given time, under the influence of gravity solely, is made the basis of calculation—this distance or a certain part of it depending on the velocity of wing stroke, a number of such per second being reckoned as the spaces through which the weight must be raised per stroke. The space passed through in a given time multiplied into the weight expresses the stored-up energy in consequence of the fall, and the mechanical power or units of work required to project the body from a state of rest to the height fallen. It would appear, therefore, but natural that the pulse of the wings at each stroke should produce a dynamical effect corresponding to that represented by the fall of the bird in the same time through the height due to the time of stroke. But when we take the time of stroke in large and slow-winged birds, the power required to be developed on this principle of calculation, in consequence of the great fall corresponding to each vibration of wing, becomes very great, and it seems obvious that the beat of wing upon so yielding a medium as air does not afford a means of storing up a supply of power corresponding to the energy of a heavy body which has fallen through a considerable space. An approximation to what appears to be nearer the correct power is obtained in the cases where the number of wing strokes is great in a given time, which leads us to the notion that the power must be supposed as applied constantly, and not by consecutive efforts, and that the terms upon which it depends are the weight of the bird multiplied by the space passed over in a given time by the centre of pressure of wing. We do not require to consider whether or no, or to what extent the upper stroke contributes to the buoyancy of the bird. It will not be disputed that if not contributing much to buoyancy, it is very effective in propulsion, and hence, in doing work which is equivalent in some ratio not yet ascertained, we have to deal with the bird in fact as we should do with our hypothetical steamer mentioned previously, supposing it were engaged in stemming a current. If just stationary, the force of the downward current on the hulls, being balanced by the reaction of the propeller, if the force of the current on the hull were known, this force multiplied by the velocity of the propeller would represent the dynamic force in action.

In like manner, as we know that the force to be balanced in the case of the bird must at least amount to its weight, this weight, multiplied by the space passed over by the centre of pressure of wing surface, will represent the power requisite to be applied to the medium of buoyancy and propulsion. As regards the power actually required in any source of power applied, we have also to bear in mind that none of our prime movers give out or apply to the mechanism on which they act, the amount of power due to the energy of the agencies of which they are the mere instruments, a certain amount being absorbed in friction and mechanical imperfections. The amount of power applied to a shaft by a steam engine, for example, can never amount to that recorded by the indicator in the cylinder, and yet, as comparative statements of the power of such engines are universally based on these indicator diagrams or records, it is necessary, when referring to them, to allow for a certain absorption of the power between the cylinder and its point of application. It is not likely that we can ever compete here either with the direct action of the muscular system in the wing, which, it is probable, is transmitted with very little loss; but if we suppose anything in the nature of a steam engine applied, it will not be safe to reckon upon a loss of less than 15 per cent. in transmission, and hence the necessary weight per horse power obtained at first, must be still farther reduced in the ratio of 85 to 100.

As an example, which is produced, however, not with a view of giving absolute results, but merely of exhibiting the method proposed, suppose a pigeon weighing 2lb. makes 180 completed strokes per minute, the centre of pressure of wings moving 9in., or, per complete stroke, 1ft. 6in., then 1·5ft. × 180 strokes = 270ft., and 270 × weight of bird, or 2lb. = 540ft.-lbs. This in a minute is 0·0163-horse power, and hence, if the proportion is to be maintained, 1-horse power must not weigh more than 122lb. This power, however, is that measured at the propeller, and, as explained above, the weight in relation to the power exhibited in the cylinder, supposing a steam engine, or any similar motor employed, must not exceed

$$122 \times \frac{85}{100} = 103{\cdot}7\text{lb.}$$

Some calculations of this kind, made several years ago, led me to the conclusion that a relation of power to weight approximately given by the above figures would suffice for the requirements of the aerial machine. The conditions did not appear to be at all the same with different classes of birds, or even with the same bird at different times. With the few I examined, which were only the ordinary pigeon, crow, and wild duck, the results seem to indicate a necessity for a motor with all accessories not exceeding from 80lb. to 150lb. in weight per horse power. On the whole, I arrived at the conclusion that with a power of one horse for every 112lb. weight, aerial navigation, in the true and comprehensive sense, ought to be possible. Now, it is to be remarked that in some of the most advanced cases, as in steam fire-engines, 1-horse power to the cylinder has been obtained from 112lb. weight, but it must be remembered that this is the weight of the lightest form of engine yet constructed with a pump and wheels for transport, certainly, but with no supply of water, no weight of passengers or parcels, no car for their conveyance, no propelling apparatus or mechanism connected therewith, while, in the weight suggested, it is obvious must be included the total weight of everything to be elevated. While, therefore, further progress appears to be necessary, there does not seem to be any insuperable difficulty in advancing so far that even the steam engine may be able to supply the power required.

It would be extremely difficult to arrive, in the present state of our knowledge, at any absolute statement, for it must be remembered also, as some former experiments showed me, that birds generally are not fully loaded, but can rise, though with difficulty, even when weighted to an extent equal to their own weight. This is also an encouraging circumstance, for while it is obvious that such a margin of power is necessary with sentient mechanism, in which exertion at full power leads to speedy fatigue and cessation of effort, such a margin is not required with inert mechanism, which continues indifferent to exertion so long as the elements of the energy it transmits (*i.e.*, fuel and water in the case of the steam engine) are regularly supplied. And this principle, if adopted, would, of course, lead to the conclusion that a yet heavier machine than we have supposed would be sufficient. There are certainly several elements connected with aerial flight which appear anomalous. The resistance of the air at the speed of wing observed, estimating by established rules, does not suffice for the reaction apparently necessary, but I am inclined to think that this may be at least partly explained by the fact that, so far as I am aware, no experiments have been made to establish the resistance of reciprocating surfaces, which it will probably be found is much greater than in the case of uniform motion in one direction.

The efficacy of a narrow blade of propeller, which is in favour of reduction of weight, has been illustrated in marine practice, not only by the fact that better results are obtained when only a small portion of the screw or spiral is used than with the fully developed thread, but also by the shape of blade found to give the best results. It was the custom (and still is in some quarters—I observe in the French marine—) to preserve a much larger amount of surface of blade at the periphery than near the centre. It is in reality found that the best results are obtained from a totally contrary arrangement, by reducing the surface or tapering the blade as we recede from the centre, and this is in fact the shape of the Griffith screw blades, now almost universally adopted in the Royal navy and the chief mail packet companies. The width of blade necessary is, in fact, smaller as its velocity increases, and it appears obvious that when the blade is just sufficiently wide to impart backward motion to the particles of the medium in which it works, any further development of it can only be injurious. There is also less development of blade necessary in a light than in a heavy medium, and hence even a much less proportion of breadth for all oblique propellers seems suitable in air as compared with water, and if we could suppose the density much diminished, as at great heights, the

Digitized by Google

most effective breadths would probably resemble (especially for high speed) more lines.

The object of the present communication is not to dogmatize on any point whatever, but to elicit opinion and to direct attention (with a view of really determining valuable data) to the importance of adding to the records of the Society all information possible regarding the performances and actual structure and proportion of birds. It is to be hoped that some models, or perhaps machines, on a larger scale may be shown at the approaching exhibition of the Society. Should there be any of the latter description, they should be tested on a weighing machine, so that their actual elevating power may be noted, even though it fall far short of what is required for ascent. By experiments at different velocities, even with an imperfect machine, valuable information might be obtained as to the law of buoyancy connected with the peculiar propeller used. All such models or machines should be considered and examined in a spirit of genial and cordial criticism, for the thanks of all promoters of human progress are due to those who give such evidence of labour in the "uphill" field of effort.

(To be concluded in our next.)

FOREIGN FITTINGS IN ENGLISH HOSPITALS.

THERE has long been a sort of inarticulate growl like the muttering of distant thunder, speaking in tones of menace to the English workman, no less than to his employer—letters in daily papers, articles in scientific journals, unpleasant experiences on the part of manufacturers who have tendered for new works. It is questionable how far the public has realized the importance of the question. Whether Mr. Disraeli or Mr. Gladstone sits on the Ministerial bench is a matter of extreme interest to those gentlemen themselves, scarcely less so to their personal friends, not indifferent to any member of the House, but of almost inappreciable influence on the actual state of the mass of the population. But whether the girders of St. Thomas's Hospital be rolled in Staffordshire or in Belgium is a matter of vital interest to that mass. For it has actually come to this, that not in one, or in two, but in many departments of manufacture the foreigner is at this moment a successful competitor with the Englishman on English ground. The last twenty years have seen an amount of competition in this country which would delight any person who believes that the unquestionable principles of political economy are, further, the most imperative motives of human action. But the competition, as a rule, has been directed only to produce the cheap. It has taken less account of the good. Good enough means good enough to sell. Thus our manufactures have been deteriorated, and we are undersold in our own markets. By a free and open competition, in which more than a dozen English manufacturers joined, for the supply of some 1,200 tons of wrought iron work alongside of the River Thames, under the very windows of the Houses of Parliament, work framed and fitted in Belgium, after designs prepared by the architect of the buildings, will support the floors of our new hospital.

Nor is this all—or even the worst. The English manufacturers may say, and the Belgian manufacturers may deny, that the quality of the material contemplated by the lowest tender, is inferior to that contemplated by the English tenders. That question, in the present instance, may, no doubt, safely be left to the decision of the architect of the building. But if Belgium pushes us in price, Westphalia pushes us in quality. There we find large works, organized with the utmost system, with the mouth of the coal-pit opening with the very *enceinte* of the buildings, in which the whole energy of the establishment is devoted to the production of the best work. The managers are highly-educated engineers, the workmen are educated men, the children of the workmen are all being trained in the schools of the establishment to fill worthily the places now held by their fathers. If a boy shows talent, he is picked out, and care is taken that his special qualification shall be developed to the full. When a workman passes the prime of his strength, he is put to lighter work. When he passes the limit of this lighter demand on his energies, he is provided for by a fund augmented by the profit of the earnings of his youth. What chance has an establishment, including perhaps an absent capitalist, a semi-educated manager, foremen risen from the forge—and distinguished, very likely, as much for the number of gallons of ale they can swallow, or the downright blow they can deliver, as for any special mechanical skill—workmen who keep Saint Monday, and a rabble of untaught incumbrances in the way of non-productive consumers—what chance has such an establishment to compete with the Westphalian factory? Distance, it may be said, will protect us. Persons who have to draw their ideas of the formidable obstacle which distance, even in these days of locomotion, opposes to business, from the difficulty which attends the transference of two or three passengers, with a moderate quantity of luggage, from the Great Western Station, at Paddington, to the Brighton Station, at London Bridge, may be excused for feeling at ease as to the proceedings of rivals in the north of Germany. But what are the facts? The Prussian Government has strictly subordinated the rate of the railway charges, to the interest of the State in promoting manufactures. Instead of three or four companies struggling for a rival traffic, which they disgorge from their termini without an attempt to facilitate its future course, everything is ordered with the aim of delivering the product of German industry, at the least practicable cost, in the market of the world. So it follows that to send, let us say, steel plates for a frigate, by a ten or a twelve hours' railway journey to Rotterdam, to ship them on a steamer, to pay shipping charges, freight, dues, landing charges, and deliver them in London, costs less, the manufacturers tell us, than to send them thither from Manchester.

What have we then to rely on? Distance is no protection. Low price is no protection. Excellence, which is the best protection, is yet sought by some of our first English houses, but their names are few. It is sought as the chief object to be attained by the German manufacturers, and the result is that they are not ashamed to compete with our very best houses, either for quality or for price. The lesson of 1848 is being taught to the world once more—taught indeed, not by cannon and by bayonet, but by means no less fatal to our industry, unless we bestir ourselves—that a mob cannot contend with an organized and disciplined force. The English workman, as long experience bids us believe, is the best raw material in the world. But, untaught and unorganized—or organized only in a self-destructive method that the foreign manufactures would gladly see kept up for yet a little while longer, every day that passes leaves him more and more behind. It would be quite worth our while, said a foreign manufacturer not long ago, to subscribe £10,000 or £15,000 a-year to the support of your trades' unions. It is not the case that the last fifteen years have seen no progress at home. The various railways that so unsystematically pierce the metropolis, furnish evidence to the contrary in their enormous viaducts. The ironwork that now spans the Thames in so many forms—that which carries Fleet-ditch over the head of the Metropolitan passenger, or that which renders hideous the entrance from Southwark to London—shows that our manufactures have advanced in their craft since Stephenson flung his tube over the Menai Straits. But if we have slowly advanced, foreign manufacture has sprung up as the creation of a day. In the year 1852, French railway companies were buying rails in South Wales. Foreign purchase was discouraged by the French Government, and disliked, for reasons both good and bad, by French engineers and directors. But they were wise enough to take what they could get at the time, while looking for something better. So Locke and Brassey made the Paris and Rouen Railway, and English houses which we could name sold rails in France. At that time such was the quality of the French manufacture that the rails cracked and crumbled under the weight of the ponderous locomotives of French design. For two English fitters to cut a foot off a good iron rail may be the work of three parts of a day. A nick round with a chisel, and a blow over a stone, and the thing was done with the rails we mention. But if a Welsh ironmaster were to base his business calculations on finding such a state of things now in existence, he would reckon without his host.

Within fifteen years, it may be said, the very idea of foreign competition with English manufacture on indifferent ground has originated. Within five years it has become no longer an idea, but a fact. Foreign locomotives have been made for English railways. "At a loss," says the English manufacturer. Most people who found a great business commence by loss—a calculated and wisely sustained loss. It may be a form of advertising—the great moral engine of the day. A reference to running engines would be a better advertisement, in our notion, than the very largest and most ingenious posters. An English manufacturer met a friend the other day in London. "What are you doing here?" he said. The other told him in confidence that he was waiting to know the result of a competition for a large quantity of work. "I fully expect the order," he said, "for I have tendered at a price by which we shall lose, merely to keep the works open." The other asked if he had any objection to exchange figures with him, as the tenders were all in, and he had himself tendered for a Belgium firm. The Englishman named his price. "You may go home, then," said the other, "I am fifteen shillings a ton below you, and it will pay our firm very well at that price." It is easy to multiply instances. But there is an obvious impropriety in quoting names, to the benefit of one tradesman, and to the discomfiture of another. And to instances given without names may be opposed the round assertion that they are imaginary. It is, therefore, a fact not to be neglected, when a large and well-known building may be pointed out as a visible illustration of the present ewing of the balance between the English and the foreign manufacturer. We shall have need of more hospitals—of hospitals, in the older sense of the term, a sense rendered in modern English by alms house, a big poor house, if we lose our manufactures. A battle lost is not a campaign, but the result of a battle of this kind shows which way the campaign is at present going. The subject is one of the deepest importance for all who care for the future of the country.—"London Review."

THE ROYAL HORTICULTURAL SOCIETY

AT the meeting of the Royal Horticultural Society, held in the Council-room, South Kensington, the show of flowers, especially of roses, auriculas, and orchids, was very splendid, but the most prominent objects were twelve new varieties of Coleus raised at the society's garden's at Chiswick, which were much admired. Mr. Bateman made some remarks on Dahlia imperialis and the orchids which were exhibited, and especial attention was called to a specimen of Odontoglossum gloriosum with two lips, which is a striking proof how little founded is the notion that they afford no abnormal instances of structure. Mr. James Batemen, F.R.S., presided, and the following candidates were elected fellows:—R. Dudley Baxter, W. Macdonald Bird, Miss Clark, Sir Wm. Clay, Bart., Mrs. F. L. Cook, Wm. Dutton, F. Halsey, Alfred Head, John Knowles, P. M. Leonard, H. Marnham, Sir W. Smith Marriott, Bart., W. W. Platt, Mrs. Plowright, Mrs. Gerald Potter, W. Skilbeck, Lady Soame, J. E. Taylor; and the Harrogate Horticultural and Floral Society was admitted into union. Joseph Hobbins, M.D., and Mr. G. M. Woodrow were elected corresponding members of the Society.

Obituary.

WE have to record the death of Captain Claxton, R.N., who has rendered signal assistance to our engineers on many important occasions. Captain Claxton distinguished himself during the Peninsular war. Later on in life he held the post of secretary to the Great Western Steamship Company, and when their vessel, the "Great Britain," was stranded in Dumdrum Bay, Captain Claxton was selected to protect the ship during winter, which he did most effectually under Mr. Brunel. Subsequently, Captain Claxton was engaged in the critical operations of floating the tubes of the Conway and Britannia Bridges, which he successfully accomplished to the satisfaction of Mr. Robert Stephenson. He has also assisted Mr. Brunel in similar operations at Chepstow. Captain Claxton, who was in his seventy-ninth year, died regretted by a large circle of warm friends.

Correspondence.

THE PRESENT CONDITION AND FUTURE PROSPECTS OF MACHINE MANUFACTURE IN RUSSIA.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—Permit me to call your attention to a very important subject for English machine manufacturers, and one which has engaged part of my thoughts for some years, while now, I believe, the time has come to bring this subject before the public, and more particularly before the mechanical part of it. In order to encroach as little as possible upon your valuable space, I must commence rather abruptly, reserving what should have been introductory remarks until you have expressed your opinion on the merits of my proposition; then will be the proper time to give those remarks in the form of statistics and proofs of the feasibility of my plan. Without further prelude, therefore, I will proceed to explain myself as well as I can.

You will see by the heading of this letter that I live at present in Russia; and it is of the condition of that country in respect to mechanics and engineering that I mean to speak. I have lived in the interior of this country and practised as a mechanical engineer for about eleven years, and have witnessed in that time changes which have all tended to the bettering of the country and the people, and, among other good things, have caused an increased and increasing demand for machinery. Owing to this increased demand, also from the extension of railroads, and other causes, the Imperial Government is very anxious to introduce

Digitized by Google

and encourage machine-making factories, and with a view to do this has made several propositions to capitalists and machine manufacturers. Although some of these propositions are very favourable, still there has as yet been no particular response made to any of them, and least of all from the wide interior.

The Government scheme, which bears more directly upon the subject to which I would wish to direct attention, is the proposed import duty on all machinery coming from abroad, which duty is intended to protect and encourage home manufacturers, and the imposition of which, although not yet decided upon, has such a strong party in its favour that I think it is very likely to be carried out. This expected increase in the price of foreign machinery naturally causes the users of machinery to inquire if the present existing Russian engine and machine makers are or will be in a position to supply their wants; or must the demand for machinery decrease when foreign competition is checked? The general opinion of people pretty well informed about the antecedents of Russian machine making, and about the unenterprising spirit of the real native manufacturer, is, that without the aid of foreign capital and enterprise employed in the country, the demand for machinery must remain unsatisfied, and consequently decrease. In this opinion my experience leads me fully to concur; but the proofs of the truth of it I cannot stop to give now: I will rather hurry on to the speculations to which this conviction gives rise.

In order to show, however, as far as my own unsupported statement can do so, that I know enough of the subject to warrant me in bringing it under your notice, I may state that I was instrumental in starting a machine factory in this town for Russian would-be manufacturers, and was for nine years trying to lick it into shape. I gave up the attempt at last in disgust; but not before I had succeeded in being the first to make a steam engine in the south of Russia, and in the latter five years made upwards of forty of different sizes. I have just finished a series of letters, written at the request of parties interested in the subject, and printed in the local newspaper, upon the present state and future prospects of Russian machine manufacturing. I turn now to you, I might almost say, at the request of the users of machinery here, in the hope that you, as an organ of British mechanical enterprise, will approve of, and perhaps publish, my proposition; while your doing so may perhaps give effect to the opinion I have here publicly uttered, that foreign machine makers will establish themselves here, and that Russia must depend for many years to come upon such domiciled manufacturers; and that not until perhaps generations of such have made their fortunes here will Russians be in a condition to compete with them.

My proposition is this:—That in order to meet the Russian demand for machinery with a proper supply, the manufacture of such machinery must (and under the changed and improving condition of the country, can) be carried on here on the spot, mostly from Russian materials, and wholly with Russian workmen. But the principal thing to be borne in mind is, that the capital for such an undertaking, and, above all, the good management and the enterprising spirit, must be imported; and I should wish them to be English. The time has come which makes such a project in this district sure of success; and if Englishmen do not take this time by the forelock, our neighbours the Germans and French will. They have been at work in a similar way to what I propose for years, and, indeed, the only successful manufacturers here in many trades are foreigners, chiefly of the above-mentioned nationalities; but with present prospects the field is so vast, that there will be employment for many more.

My reasons for saying that the time is now come when the success of such a project may be said to be as sure as that of all human projects can be, are founded upon the following considerations:—Firstly, on the increase of commercial confidence, caused by the late reforms in the courts of law, and in the administration of justice, the beneficial effects of which change are becoming every day more manifest. Secondly, on the extension of railway communication, more especially the late concessions; for instance, the town from which I write, often called the third capital of Russia, will, in the course of a year and a-half, be in direct communication by rail with Moscow and St. Petersburg, and, in the course of three years, with the coalfields and iron mines of the Don, with the river depôts of Siberian iron and copper, and with the sea of Azoff. My third argument is self-evident and of general application in all civilized countries, —that is, that a supply of good machinery at fair prices will create an increased demand. The demand, however, exists already, which I am willing to prove, if you will allow me to do so; for the present I will only point to the fact, that the number of locomotives ordered from abroad by Russia in the last three years was 600, for already existing railways, and for this year there are already ordered 179, and that before the concession was given for the Koursh-Khaskoff and the Khaskoff-Taganrog railways. In connection with this line of railway there is an immediate opening for a waggon factory, as there is none nearer than Moscow, where an Englishman has established one within the last few years, and by the terms of the contract, all the waggons, and as much of the rolling stock as possible, must be made in Russia. My fourth and last reason is, I am sorry to say, founded upon the reports of the stagnation of trade in England, whilst, at the same time, there seems to be no want of capital, or of engineering enterprize.

It would be quite superfluous in me to make any remarks about the ills of expatriation to men who are covering the world with their works, and are, like other Alexanders, searching for more worlds, not perhaps to conquer, but to civilize, it is only necessary to remind them that Russia is one of England's nearest neighbours, and is every day approaching nearer. One other remark only I allow myself to make, and that is, that I have ever found a spirit and feeling abroad among all classes of Russians towards England, and for Englishmen, which I should very much wish to see reciprocated more warmly from our side. My proposition, therefore, to put it in plain words, is this:—To start with English capital, and under English management, here, in the centre of the south of Russia, a large engine factory or factories, for the construction of locomotive, portable, and stationary engines and boilers, the manufacture of machinery for beet-root sugar making and refining, the fitting out of gas and waterworks; in short, all the heavier classes of engines and machines. In this crude state I leave my project in your hands, holding myself in readiness to furnish you, or any parties who may be inclined to take it up, with full particulars and statistics of the more than probability of success to such an undertaking, if entered into with our usual national spirit.—I am, Sir, yours, &c., ALEXANDER CAMERON,

Member Russian Technical Society.

Khaskoff, Russia, March 19, 1868.

[We thank Mr. Cameron for his valuable and highly suggestive letter, and shall be glad to hear further from him upon the subject, which is one of vital importance to our manufacturing engineers. We invite the opinions of our readers upon Mr. Cameron's proposition, our own being that it merits the earnest attention of engineers, not only on private, but upon public grounds.—ED. M. M.]

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith.—ED. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

Naval, Military, and Gunnery Items.

A RETURN issued on Saturday shows that the number of her Majesty's ships and vessels at the different stations over the world on March 31, 1867, was 276; the total complement of men 44,245.

THE "Messager" of Cronstadt gives some details of the improvements which are being introduced into the Russian artillery. The vessels are already armed with 8-inch breech-loaders, and 15-inch smooth-bore guns. A successful trial has been made with a 9-inch piece made by M. Krupp; 700 shots were fired without the cannon being at all damaged. For the maritime fortresses, a brass gun of 11-inch bore, and to weigh 845lb. (84lb. each) has been projected. Trials are being made of 8-inch iron guns with steel hoops.

A correspondent of "Notes and Queries" says:—I have heard or read an anecdote which Earl St. Vincent's reverence for the quarter-deck reminded me of. Lord Cornwallis went out to India as Governor General in the ship of his brother, Admiral Cornwallis. One sultry day the admiral, coming up from his cabin, caught sight of his brother lounging on a chair in his dressing-gown. After chafing some time under this, and not liking to come into collision with the Governor General, he turned gruffly to his first lieutenant and said, "Go and tell that land lubber to get up from his Majesty's quarter-deck."

Another western steamboat has blown up. The "Magnolia," which left Cincinnati for Maysville, Kentucky, on March 18, with over 100 passengers, and heavily laden with freight, exploded her boilers on the Ohio river, about twelve miles above Cincinnati. The boat afterwards caught fire, and of the persons on board, who, with the crew, numbered 160, but 57 are known to have been saved, the others being drowned or burnt to death. Among the lost are the captain of the boat and a large number of ladies. The boat is a total wreck, for after the explosion some gunpowder which was on board caught fire and blew up the hull, destroying everything.

The "Courrier de Bayonne" gives it as certain that the Minister of War has decided on forming a camp of instruction for 1868 at Lannemezan (Hautes-Pyrenees). The troops will be composed of four regiments of infantry, a battalion of chasseurs, a brigade of cavalry, consisting of three regiments, and the usual accessories of artillery, engineers, &c. This decision will give great animation to the district, and we are assured that the Emperor will visit the place to satisfy himself if there is any possibility of giving to it the proportions of Chalons. The 77th regiment of the line, at present in garrison at Bayonne, will go there for two months and be replaced by the 58th, now at Pau.

THE Russian merchants are yearly continuing to develope the internal resources of that empire by means of steam navigation. The Tyne has largely supplied Russia with steam vessels, and this spring a number of orders have been completed. Messrs. Lesslie and Co. have finished a fleet of steam lighters of considerable tonnage for river service on the Black Sea; and Messrs. Charles Mitchell and Co. have completed a steamer of 300 tons for the commissioners for improving the Don estuaries; they have also on hand a paddle steamer for the Volga, and a steamer named the "Alexander," intended for the service between St. Petersburg and the principal towns on Lake Onega. She is 500 tons, will have engines of 120-horse power, will have accommodation for three classes of passengers, and is specially designed for river service and for open water.

MR. PETERS, an economical Member of Congress from Maine, has distinguished himself by introducing a bill which practically abolishes the United States Navy. His bill relieves all naval officers at the age of sixty; abolishes all the grades except captain, commander, lieutenant, and master, and suspends the naval academy at the close of the academic year! The fault of the bill, says the American "Army and Navy Journal," is that it does not go far enough. Mr. Peters ought to add provisions for the immediate sale of all the vessels in the navy, for the closing of all the navy-yards, and for dispensing with the Navy Department. Then he should introduce an analogous bill for abolishing all grades in the army except colonel, major, captain, and lieutenant; suspending the obnoxious Military Academy; and dismantling all the forts; and closing all the arsenals in the country. By so doing what untold millions would be saved!

Miscellanea.

THE number of visitors to the Patent Office Museum, South Kensington, for the week ending April 4, was 3,134; total number since the opening of the museum, free daily (May 12, 1858), 1,270,767.

MR. WINWOOD READE will sail in a few weeks for the Gold Coast, and will probably commence by exploring the Assinie river. Mr. Reade will travel under the auspices of the Royal Geographical Society.

THE Post-office department having now to carry official correspondence without charging the postage to the several Government offices, have given an estimate of the quantity for the year. It is calculated at 14,121,000 ounces.

A RAILWAY bridge in course of construction over the Dnieper, near Smolensko, for the line between Vitebsk and Orel, has been destroyed by fire. The loss is estimated at £16,000. The cause of the disaster is not known.

The village of Valbella Superiore, in the Milanese, was a few days back entirely destroyed by fire. An old woman, a young girl, and twenty-nine head of

Digitized by Google

cattle, perished in the flames. Six hundred and forty persons have been reduced to destitution by this catastrophe.

THE visitors to the South Kensington Museum during the week ending April 4, were, on Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 9,751; on Wednesday, Thursday, and Friday (admission 6d.), from 10 a.m. till 6 p.m., 1,988; total—11,739. Average of corresponding week in former years, 9,763; total from the opening of the Museum, 7,279,371.

MR. THOMAS PAYNE, of the Detroit and Milwaukee Railroad, has lately invented a contrivance to indicate to railway passengers the station which they are approaching, its distance from the one last passed, and from that point to each terminus of the road. It is placed in the centre of the car, and has two arms projecting about two feet from each side of the car, which coming in contact with posts placed for the purpose, turn the indicator immediately after leaving each station

THE total value of the iron and steel, and manufactures of these metals, imported by the United States of America in 1867, was 26,465,763 dollars; coal imported, 468,722 tons, value 1,334,261 dollars. The exports of oils, coal, and petroleum amounted to 66,330,084 gallons, value 19,210,242 dollars; refined petroleum, 59,208,965 gallons, value 17,926,782 dollars. The total imports for the year 1867 were of the value of 378,629,945 dollars, and the exports of the value of 463,398,863 dollars, yielding a good cash balance in favour of the States.

AT the last ordinary meeting of the Society of Engineers, held on Monday, the 6th inst., Mr. Baldwin Latham, President, in the chair, the following candidates were balloted for and duly elected as Members:—Messrs. James A. Hay, Royal Arsenal, Woolwich; Richard Dudgeon, London-wall and Columbia-street, New York; and Robert Joseph Hutton, Fairfield, Glasnevin, Dublin. As a Foreign Member, Lieutenant George Gordon Bigsby, Royal Engineers, Executive Engineer, Public Works Department, Bengal. As Associate, Mr. John Thompson, Nettlebed Potteries, Oxfordshire.

AT the general monthly meeting of the Royal Institution of Great Britain, held Monday, April 6, 1868, Colonel Philip J. Yorke, F.R.S., Vice-President, in the chair, Mr. R. M. Beachcroft; Mr. Matthew Boulton; Mrs. Cattley; Mr. Roger Eykyn, M.P.; Mr. William Millar; Mr. C. H. Mills; Mr. Donald Nicoll; Mr. Charles Pemberton; Mr. A. G. Potter; Sir George R. Prescott, Bart., and Sir Henry Thompson, F.R.C.S., were elected Members. Special thanks were returned for the following addition to the Donation Fund for the Promotion of Experimental Researches:—T. W. Helps, Esq., third donation, £10.

OUR French neighbours, recognizing the close relationship between horticulture and the fine arts, have taken steps to cement the alliance. We, "Gardeners' Chronicle," are able to announce that the Societe Imperiale et Centrale d'Horticulture intend to organize a special horticultural display in connection with the "Exposition des Beaux Arts," from the 1st to the 8th of May next, and to prolong it, with such decorative plants as can be retained, or renewed, till the 20th of June. The joint exhibition will be held in the garden of the Palais de l'Industrie. Horticulturists of all grades and nationalities are invited to take part in the display, and are encouraged so to do by the offer of prizes.

THE Indians seldom molest the telegraph wires, because at an early period they were led to believe that the "Great Spirit" was the presiding genius, a circumstance strengthened by the mysterious communication of thought. Some, however, doubted it, and one day a young Sioux Indian determined to show that he had no faith in the "Great Spirit's" connection with the wires, so he set to work with his hatchet to cut down one of the telegraph poles. A severe thunderstorm was going on at a distance; a charge of electricity being taken up by the wires was passed to the pole which the Indian was cutting, which resulted in the death of the Indian. For a long time thereafter the telegraph line was not molested.

IN Tuscany there are four mines of quicksilver, but at the present time three have been abandoned on account of the low price now obtained for this metal. The only mine now worked is that of Siele, near Castelazara. The quantity of ore extracted in 1864 was 3,000 quintals (300 tons), which yielded from 2 to 2¼ per cent. of quicksilver—about 6,000 kils. Quicksilver is also found in the neighbourhood of Agordo, in the Venetian provinces. The veins of sulphide of mercury are said to be most extensive but are worked on a very small scale. The following is the annual produce of quicksilver in Italy:—

Mines.	Quintals.	Value.
Castelazara . . .	3,000 . . .	3,600 francs.
Agordo	44,608 . . .	63,000 „
Smelting Works.		
Castelazara	66 . . .	34,200 „
Agordo	230 . . .	91,840 „

From 1863 to 1865 the imports of quicksilver were 10,900 kils., of the value of 71,100f.; and the exports 1,000 kils., of the value of 2,700f.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

BOILERS AND FURNACES—2611, 2638, 2670
BUILDINGS AND BUILDING MATERIALS—2612
CHEMISTRY AND PHOTOGRAPHY—2606, 2608, 2618, 2656, 2666
CULTIVATION OF THE SOIL, including agricultural implements and machines—2582, 2583, 2627, 2639, 2640, 2659
ELECTRICAL APPARATUS—2599, 2622
FIBROUS FABRICS, including machinery for treating fibre, pulp, paper, &c.—2581, 2590, 2597, 2613, 2623, 2624, 2628, 2642, 2658, 2660, 2664
FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—2652, 2661
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c—2594, 2619, 2649, 2655
GENERAL MACHINERY—2580, 2586, 2588, 2607, 2609, 2610, 2621, 2633, 2635, 2636, 2645, 2651, 2663, 2665
LIGHTING, HEATING, AND VENTILATING—2584, 2629, 2641, 2643, 2648, 2668
METALS, including apparatus for their manufacture—2596, 2637, 5657
MISCELLANEOUS—2585, 2589, 2593, 2595, 2601, 2602, 2603, 2604 2614, 2615, 2616, 2620, 2626, 2631, 2632, 2634, 2644, 2646, 2647, 2650, 2662, 2667, 2869, 2673
ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—2591, 2598, 2617, 2653, 2671
SHIPS AND BOATS, including their fittings—2592, 2605
STEAM ENGINES—2600, 2625
WARFARE—2587, 2630, 2654, 2672

2580 W. F. COOKE. *Improvements in tunnelling and quarrying slate and other minerals, and in machinery used for these purposes.* Dated September 11, 1867.

The patentee claims, first, tunnelling or quarrying slate and other minerals with a tunnelling machine working in combination with a traversing machine to cut parallel tunnels into the slate or mineral, as described. Second, tunnelling or quarrying slate and other minerals with a tunnelling machine cutting into the slate or mineral parallel tunnels intersecting one another, as described. Third, the quarrying by cutting into the slate two parallel rows of tunnels, one above the other, or at a distance from one another, and afterwards sawing or cutting away the block of mineral between the two rows of tunnels, as described. Last, constructing tools in the manner described for cutting away at the back of a circular block of slate or mineral which has had a groove cut around it by a tunnelling machine.—Patent completed.

2582 H. STEWART. *Improvements in driving the saw-blade cutters of reaping machines.* Dated September 12, 1867.

This invention consists in the application of a drum or pulley to the wheels or axle of a reaping machine. The drum or pulley has a zig-zag groove recessed into its periphery; a sliding block, stud, or roller attached to a lever works in the zig-zag groove, and causes the lever to vibrate upon a fixed centre. The outer end of the lever is attached by a connecting rod to the saw blade cutter, to which it imparts a reciprocating motion.—Patent abandoned.

2583 J. WILDERSPIN. *Improvements in the construction o horse rakes.* Dated September 12, 1867.

This invention consists in the combination and arrangement of certain mechanism whereby the lines or teeth of horse rakes can be raised, and the load accumulated thereon discharged, in a simple and effectual manner.—Patent completed.

2584 J. PERRIN. *An improved fuel economizer.* Dated September 12, 1867.

As it is probable that an extension of time for completing this patent will be petitioned for, the documents relating to the invention cannot at present be seen.

2585 J. W. HALFPENNY. *Improvements in tobacco pipes.* Dated September 12, 1867.

In this pipe the smoke passes through an orifice in the clay lining, where it becomes separated from the oil, the latter being retained in a conical chamber, whence it passes through the orifice first mentioned into a receptacle provided for the purpose at the bottom of the pipe, the smoke thus passing through into the stem entirely freed from the essential oil.—Patent abandoned.

2586 C. OATES. *Improvements in fire-escapes and ladders.* Dated September 12, 1867.

This invention comprises, among other features, the following:—Upon the axle of a pair of wheels, which serve as the means of transport of the fire-escape, two parallel levers are mounted, the axle serving as the fulcrum on which the levers turn. The longer arms of the levers serve as handles with which to push the fire-escape about on its wheels, as well as to raise and depress the short arms of the levers. The handles are connected near their ends by a cross-piece. The levers, axle, and wheels and cross-piece constitute a carriage on which the ladder of the fire-escape is supported and carried. The ladder is compound, consisting of two or more ladders sliding within one another, telescope fashion, the inner ladder being raised within the outer one by an endless chain, which passes over pulleys at the top and bottom of the outer ladder, to which chain the inner ladder is fastened near its lower end.—Patent abandoned.

2587 J. R. COOPER. *Improvements in breech-loading fire-arms.* Dated September 12, 1867.

Here the opening of the breech, the withdrawal of the case of the exploded cartridge, and the cocking of the hammer, are effected at one operation. The invention is especially applicable to central-fire guns, but may also be applied to guns in which the firing is not central. The patentee closes the breech of the gun by a closing block hinged to the side of the shoe or open breech chamber, and capable, by turning upon its hinge, of being shut down into or raised from the breech chamber. A spring acting on the joint of the closing block lifts it from the breech chamber and supports it in its raised position when the said block is at liberty to move. The hammer is jointed on the under side of the barrel, and on its liberation by pressure upon the trigger is forced upwards and made to strike the striker and discharge the cartridge. On the centre on which the hammer turns is an arm or lever which works in a slot at the back of the breech chamber. The top of this lever is provided with a comb or thumb-plate by which it is moved. A spring presses the lever into its raised or original position, and a projection on the front of this lever projects over the breech-block when the latter is shut down, and fixes it in its place during the discharge. On shutting down the breech-block, it presses upon the inclined upper side of the projection, and, forcing it back, causes it to snap over the block and bolt it down. When the arm or lever is depressed, it bears against the front of the hammer, and carries the hammer down until it reaches its cocked position. The cartridge-case extractor consists of a bar sliding in a slot in the breech chamber. The bar carries at its front a hook against which the rim of the cartridge bears, and at its rear end engages with the lever described. When the lever is drawn back, it draws back the extractor, and when the lever advances, the extractor moves forward.—Patent completed.

2588 W. BROWN. *Improvements in machinery for rolling hoops, strips, angle bars, and other bars of iron and steel.* Dated September 12, 1867.

The patentee claims, first, the arrangement or combination of two sets of rolls, one set on each side of the billeting or reducing rolls, substantially as described. Second, the combination with the said rolling machinery of two or more pairs of hard or planishing rolls, substantially as described and illustrated. Third, making in the billeting or reducing rolls of the said rolling machinery flattening and edging grooves, or edging, flattening, and edging grooves, substantially as described and illustrated. Also, when bars of small size are to be rolled, making the billeting or reducing rolls of the said machinery with elliptical and square grooves alternating with one another, substantially as described and illustrated. Lastly, making the grooves of ordinary three high billeting or reducing rolls with flattening and edging grooves, substantially as described and illustrated.—Patent completed.

2589 H. SYMONS. *Improvements in fireguards and fire screens.* Dated September 13, 1867.

This invention consists in making fireguards and fire-screens of a number of leaves made in various designs, either of plate metal or variegated wirework, each of which leaves has an entirely independent action, and revolves upon an axis which is attached to hooks adapted to fit on the bars of any stove or grate ordinarily used in domestic dwellings.—Patent abandoned.

2590 P. R. COUCHOUD. *Improvements in machinery for manufacturing chenille.* Dated September 13, 1867.

This invention consists, first, in the employment of an endless wire composed of one or more threads, contiguous with which are the chenille threads, pressed and maintained against the wire by rollers moved by a constant and regular force actuated by springs concealed in slots or otherwise. Second, the formation of the filamentous gut or cord forming the chenille by a circular creel bearing an unlimited number of threads, either single or complex, carried on bobbins or reels which, participating in the circular motion of the creel, wind the threads round the endless wire, and so form the filamentous cord. Third, the adaptation of two chenille threads, which, being wound on two different bobbins or reels, serve to close the pieces of gut and may be grouped in pairs of two, four, or more round the endless wires, so as to make a like number of chenille simultaneously, which has not previously been attempted. Fourth, the adjunction of a circular knife having either an eccentric rectilineal motion, or fixed with an oblique edge, by which a continuous manufacture is carried on. Fifth, the winding of the chenille on a receiver or receivers having a rotary motion producing the requisite twist, no matter what may be the form or position of the receiver, the principal characteristics of which are—first, that the twist may be varied according to desire or necessity; and, second, that the chenille is in no way injured by pressure.—Patent completed.

2591 J. REID. *Improvements in apparatus for finishing parts of locomotive wheels.* Dated September 13, 1867.

This invention relates, principally, to the crank pin holes in locomotive wheels, and the improved apparatus comprises arrangements for accurately adjusting a pair of wheels by the journals of their axle, for insuring the crank pin holes being accurately in planes at right angles to each other, and parallel to the journal axis, and for forming these holes with a uniform and correct taper. The improved details for forming the taper are also applicable to the axle holes.—Patent completed.

2592 F. A. PAGET. *Improvements in preventing the deviation of the compasses of iron or steel ships.* Dated September 13, 1867.

In his provisional specification the inventor states that he claims the following:—First, demagnetizing or altering the state of the magnetism of iron vessels, or any parts of or on such vessels, by encircling the vessels or the parts of or on such vessels with an electric spiral or spirals, as described. Second, the employment of any kinds of galvanic battery for the purpose of supplying the electricity to such an electric spiral or spirals. Third, the employment of any kind of magneto-electric machine for the purpose of supplying the electricity to such an electric spiral or spirals. Fourth, the employment of any kind of induction apparatus in combination with a battery. Fifth, the employment of any commutator, or any rheostatic apparatus, for regulating the currents from the battery, or from the magneto-electric machine. Sixth, the employment of men with diving dresses for winding or unwinding the insulated metallic wires round the hull. Seventh, the employment of the insulated wire in the form of open rings, which are afterwards united together by any known means. Eighth, the combination of this process with that by which the plates are rubbed with a permanent or electro-magnet, which latter process, however, he does not claim by itself —Patent abandoned.

2593 W. F. BATHO. *Improvements in apparatus for heating, evaporating, and cooling liquids.* Dated September 13, 1867.

The patentee claims, first, making that part of the apparatus in which the heating and evaporating is effected, or which when used as a refrigerator contains the refrigerating liquid, of a coil or coils of pipes, combined with a series of pendant tubes, substantially as described and illustrated in the drawings. Second, the construction described and illustrated in the drawings of a deflector or guide for the pendant tubes of apparatus used for heating, evaporating, and cooling liquids, by means of a screwed bush of brass, or other non-corrosive metal or alloy at the top of the said outer tube, as described.—Patent completed.

2594 R. LOWE and J. TAYLOR. *Improvements in the manufacture of articles of jewellery.* Dated September 13, 1867.

Here the patentees form the body or foundation of the article of wire gauze, made of gold wire, or wire of other metal or alloy. The wire gauze is readily fashioned into the required shape, and the figure of the article is secured by an edging made of a piece of open-jointed tubing of small diameter.—Patent completed.

2595 J. M. NAPIER. *Improvements in wine glasses, and in stands or holders for the same.* Dated September 13, 1867.

This invention has for its object improvements in wine glasses which are not provided with a foot or base, and in the stands or holders for supporting them (such as are described in the specification of a patent, dated March 11, 1865 (No. 693), and consists in furnishing such wine glasses with movable stems, of any suitable material, attached to the bowl of the wine glass by screw, spring, or other convenient fastening, so that they may be removed and replaced with ease.—Patent completed.

2596 S. DALTON. *Improvements in the manufacture of iron and steel.* Dated September 13, 1867.

The patentee claims treating iron in a manner similar to the puddling or boiling process until it is in a state fit to be balled or made into blooms for shingling or rolling, and then, in place of so doing, melting the metal and casting it into moulds. He also claims adding spiegeleisin, or other cast iron, to the puddled or boiled metal when it is in a state fit for balling or forming into blooms for shingling or rolling, and, when the mixture is thoroughly melted, casting it into moulds. He also claims constructing furnaces having flues under the working bed, in the manner set forth.—Patent completed.

2597 W. WHITEHEAD. *Improvements in printing fabrics, or in producing patterns thereon.* Dated September 13, 1867.

Here the patentee prepares the fabric (which he prefers should be of silk or wool) by dyeing it with an aniline colour; it may be magenta or purple, or other dye, such as is prepared from aniline, and he then prints upon the fabric so dyed the pattern desired, using for this purpose an alkali (he prefers potash) thickened with gum and sulphate of lead; or it may be other powder which will prevent the pattern spreading. He then places the piece in a steambox together with red prussiate of potash and oxalic or other acid, and the steam being turned on, a gas is generated which, acting with the material which has been printed on to the fabric, discharges the aniline dye in the parts on to which the alkali has been printed, and so a white figure is obtained.—Patent completed.

2598 H. A. BONNEVILLE. *A new and improved railway brake.* (A communication.) Dated September 14, 1867.

This invention consists in interposing the bent back lower ends of the iron blocks between the wheels and the rails. The blocks of each carriage are secured by connecting rods, and the whole is suspended on rollers at the upper ends of the blocks and rolling on an iron bar placed in an inclined plane, and forming part of a frame fixed under the carriage. Each apparatus is connected with the following and the preceding one by iron bars, and the keys which may be taken off at will to set the carriages free from each other when desired. The apparatus of the first carriage is connected with a piston rod working in a special cylinder of the steam engine. By actuating this piston all the blocks are repelled backward, and at the same time lowered to a level with the rails, the rollers run along the inclined planes from the front towards the rear; each wheel then mounts on its corresponding block and slides with friction on the rail, thus operating the stoppage of the train.—Patent completed.

2599 W. G. BROWNSON. *Improvements in telegraphic apparatus relating especially to telegraphic relays, repeaters, and commutators.* Dated September 14, 1867.

The documents relating to this invention cannot at present be seen, an extension of time for completing the patent having been petitioned for.

2600 W. E. NEWTON. *A mode of increasing the efficiency of steam for motive power purposes.* (A communication.) Dated September 14, 1867.

The object here is to increase the efficiency of steam as a mechanical agent for driving machinery, &c., by employing in conjunction with it highly heated air under pressure from an air forcing engine, and mixing this air and steam together in the steam chest on their way to the cylinder of the engine. By these means a retreating or superheating of the steam, after it leaves the boiler, and while it is confined within the steam chest and cylinder, will be effected. Reference to the drawing is necessary for a full description of the invention.—Patent completed.

2601 J. ANTILL, G. GRIMES, and H. C. TUNKS. *Improvements in the construction of cores used in casting metallic pipes or tubes of a curved or syphon form.* Dated September 14, 1867.

This invention consists in forming the cores of such a material that they may be easily broken to pieces and removed from the interior after the casting is completed. The substance the inventors make use of is the ordinary plaster of Paris, which they mix up with hair, cotton, or any other animal or vegetable fibrous material, in order to bind and strengthen it.—Patent abandoned.

2602 H. A. BORDIN. *An improved means and apparatus for preventing sea-sickness.* Dated September 14, 1867.

The patentee makes use of a flexible bandage or apparatus to go round the upper part of the human face, and so adapted that, when suitably pressed by the fingers, or kept air-tight by any other suitable means, the light shall be excluded from the eyes, whilst, in order to prevent the apparatus from pressing on these latter, or injuring them, two protuberances are formed in the apparatus opposite and over the eyes so as to allow to these latter their free movement. The apparatus can be fixed to the head of an elastic band, or any other convenient fastening.—Patent completed.

2603 R. CANHAM. *Improvements in means or apparatus for sharpening knives and other edged articles, which improvements are also applicable to grinding and polishing various surfaces.* Dated September 14, 1867.

This invention consists, first, in the employment of cylinders or rods of steel, stone, or other suitable material, fixed on end at any desired angle to each other, and mounted in suitable holders, with or without capability of adjustment to different angles, according to the particular angle desired to be given to the edge of the instrument to be sharpened. The invention also consists in the employment of suitable guides to maintain the knife or other article in the desired position whilst sharpening the edge.—Patent completed.

2604 J. JEYES. *A new or improved material to be used as a substitute for oiled silk, bladders, gut skins, india-rubber, and other waterproof materials and leather.* Dated September 14, 1867.

The patentee takes blotting paper, tissue paper, or thick paper, and covers or saturates the same on one or both sides with a solution or compound of the following ingredients:—Gutta-percha about one part, gum shellac about one part, coal tar about two parts, and methylated spirit about four parts. The gutta-percha, shellac, and tar are to be mixed separately from the spirit at a temperature of about 212deg. Fah., and then the spirit is to be added so as to form a complete solution of the ingredients.—Patent completed.

2605 P. CRAUSE. *Improvements in propelling boats, ships, and other vessels.* Dated September 16, 1867.

This invention consists in the employment of a cylinder or cylinders closed at the inner and open at the outer end, and inserted in the side or sides of the vessel, in which cylinder or cylinders is or are contained a similar cylinder capable of working therein by the action of the piston rod of a steam engine. The inner cylinder is driven and caused to act as a piston or plunger on the water by a rod passed through the closed end of the outer cylinder, and connected to the piston rod of the engine or other motive power. There are other features comprised in the invention.—Patent abandoned.

2606 G. PICKIN. *Improvements in the treatment and preparation of mineral oils and spirits for illuminating and other purposes.* (Partly a communication.) Dated September 16, 1867.

This invention has more particularly for its object improvements in the preparation and treatment of volatile oils or spirits obtained by the distillation or refining of petroleum, shale, or coal oil, or gas tar, or other analogous mineral oils, whereby the illuminating power of such spirits or light oils is improved, and by which means they are rendered safe and free from danger by explosion or ignition by contact of flame with the vapours. And for the purpose of carrying out the improvements as above described the patentee takes a quantity of light oil or spirit, and to every hundred gallons by measure he adds the following ingredients, viz.:—Of pulverized hemlock bark, 1½lb.; of flax seed, 1½lb.; of white oak bark, 4lb. to 5lb.; of muriate of soda or common salt, 3lb. to 5lb.; these are to be carefully mixed with a portion of the bulk of the spirit or other light oils, and after being steeped for a sufficient time are to be strained off through suitable strainers or bags, and then returned to the main bulk of the spirit or oil.—Patent completed.

2607 J. A. M'KEAN. *Improvements in machinery for cutting rocks.* (A communication.) Dated September 16, 1867.

This invention will probably be described and illustrated in a future number of this journal.—Patent completed.

2608 P. DUMONT. *An improved manufacture of soap.* (A communication.) Dated September 16, 1867.

The soap forming the subject of this invention, and which the inventor calls mineral soap, is composed of potash of commerce, animal fat, cocoanut oil, river water, carbonate of potash, and fine sand. The proportions are as follows:—Potash of commerce, 6 kilogrammes; animal fat, 22 kilogrammes; cocoanut oil, 2 kilogrammes; river water, 9 kilogrammes 950 grammes; carbonate of potash, 50 kilogrammes; fine sand, 50 kilogrammes.—Patent abandoned.

2609 G. F. BRADBURY and T. CHADWICK. *Improvements in, or applicable to, sewing machines.* Dated September 16, 1867.

We cannot here give space to the details of this invention.—Patent completed.

2610 W. J. CUNNINGHAM. *Improvements in means or apparatus to be employed to sewing machines, and to other machines wherein cams or cam surfaces are employed working in connection with trucks or rollers, by means of which they are in working rendered comparatively noiseless.* Dated September 16, 1867.

This invention is not described apart from the drawings.—Patent completed.

2611 C. HOLSTE. *Improvements in blast furnaces.* (A communication.) Dated September 17, 1867.

This invention relates to improvements in the hearth of blast furnaces in which the scoria or slag is continually discharged, but in such manner as to remain at the same level within the hearth with as little fluctuation as possible. The hearth is completely closed by carrying the walls to the bottom on all sides the tymp; the fore part of the hearth, and the dam used heretofore in blast furnaces, are done away with by this construction.—Patent completed.

2612 W. LE DUC. *Improvements in the mode of covering roofs with slate or other materials, which improvements are applicable also to the covering or forming of walls.* Dated September 17, 1867.

Here the pieces of slate, &c., are made in the form of squares, having two of their corners situated diagonally opposite to each other cut off or removed, so that the piece of slate when prepared for use presents the form of a six-sided figure. In laying the pieces of slate they are arranged in horizontal rows, with their shorter sides in juxtaposition, the lower rows being first laid, and each succeeding row above so placed that its lower corners overlap and cover the joints or intervals between the shorter sides of the pieces of the lower row.—Patent completed.

2613 W. BRAILSFORD and J. GADSBY. *Improvements in the manufacture of lace made on bobbin net or twist lace machines.* Dated September 17, 1867.

The patentees claim the arrangement of the warp threads and bobbin threads in such manner as to produce an open ground or mesh in conjunction with fine weavings, and the ornamentation thereof by the use of embroidering threads, so as to present a resemblance to the pillow or hand-made lace known as "Chantilly" lace, as described.—Patent completed.

2614 J. C. BAYLEY and D. CAMPBELL. *Improvements in firelighters and fire revivers.* Dated September 17, 1867.

This fire-lighter consists of a mixture of wood sawdust, turnings, or shavings, and resin. The resin must be first melted and the sawdust or other materials above mentioned added to it; when thoroughly incorporated the composition is moulded into the required forms, and when dry is ready for use.—Patent abandoned.

2615 T. TURNER. *Improvements in mounts or holders for maps, tablets, prints, blinds, and similar articles.* Dated September 17, 1867.

This invention consists in constructing mounts or holders of two half rollers or cylinders—that is so say, a roller or cylinder divided longitudinally, and in providing means for fastening the half rollers or cylinders together at each end. This provision for fastening consists either of a circular groove formed near each end of the roller to receive an elastic band, or of two plain or internally threaded conical or other suitably formed caps made to receive the two ends of the roller which are of corresponding form. The top of the map, tablet, or other article or articles to be held is placed between the two rollers, and the elastic bands or caps are then fitted over their ends, so as to keep them together, whereby the map or other article is securely held between them.—Patent completed.

2616 S. JAY. *A new or improved apparatus for adjusting or securing scarfs, neckties, and other articles of apparel.* Dated September 17, 1867.

The object here is to prevent scarf and neck-ties from rising up the collar, and the invention consists of two main parts, viz., one or more turned-down pins or points which are inserted into the article to be adjusted or secured, and one or more turned-up hooks, preferably flat, to take under another article of apparel, which, in the case of scarfs and neck-ties, would be the collar. These two parts are connected together by a piece of tape and their distances may be adjusted as required.—Patent abandoned.

2617 S. C. AMESBURY. *Improvements in apparatus for communicating between passengers and guards of railway trains, and between guards and engine drivers of railway trains.* Dated September 17, 1867.

This motive power communication and connection is by means of the axle of the carriage or van, and communicating with an alarm apparatus in such a way that, on a handle inside the compartment being displaced while the train is in motion, an alarm is at once mechanically set going. The alarm may be of various construction, and is to be actuated by a belt or chain encircling the axle of the carriage or van.—Patent abandoned.

2618 T. BELL. *Improvements in treating the oxide of iron residues of gas purifying, in order principally to extract sulphur therefrom.* Dated September 17, 1867.

Here the inventor treats the oxide of iron residues with bisulphide of carbon, by which the sulphur is taken up from the oxide; afterwards he draws off from the oxide of iron residue as much bisulphide of carbon as practicable, and treats it again and again in a similar manner with fresh bisulphide until there is no sulphur remaining in the oxide. He afterwards distills off, and so recovers the remaining bisulphide, leaving only cyanides and a few other impurities in the oxide of iron, which may be afterwards burnt off or otherwise removed. To obtain the sulphur from the bisulphide of carbon he subjects it to distillation, by which the bisulphide is driven off and recovered to be again used, and the remaining sulphur may be afterwards melted and formed into cakes or bars for use.—Patent abandoned.

2619 D. GARDNER. *Improvements in spring mattresses, sofas, couches, and chairs.* Dated September 17, 1867.

This invention consists, essentially, of a mode of binding or fastening and retaining the helical volute or spiral conoidal wire springs forming the main resting or seating part of spring mattresses, sofas, couches, and chairs, in their proper position, ranged in horizontal, parallel, straight rows at any desired distance apart, both longitudinally and transversely, so as to cross each other at right angles or diagonally at any other desired or suitable angle, by long flat straps or bands of thin rolled iron or steel (or in place of each flat band one or more wires might be employed) lying in the same direction as the rows of springs, and across the axial line of their ends where the bands are made to cross each other and be laced under and over the end coil of the springs, so as to bind the springs to the frame or set of straps crossing each other, by preference in a lacing manner alternately over and under each other, as well as being so laced to the last wire at each side of the springs.—Patent abandoned.

2620 T. STEVENSON. *Improvements in the manufacture of faggots or firelighters.* Dated September 17, 1867.

This invention consists in arranging the radial pieces of wood, which are of uniform length, round a central core or nave on which the inner ends of the radial arms or pieces press uniformly. The outer ends of these radial pieces fit or rest in grooves or indentations made or cut in the curved pieces which form the outer rim or felloe of the wheel. When the whole are bound together with an enveloping string, and the wheel is dipped in melted resin, the article will be ready for use.—Patent abandoned.

2621 A. M. CLARK. *Improvements in valve closet apparatus, part of which is applicable for regulating the flow of water in other cases.* (A communication.) Dated September 17, 1867.

This invention consists, first, in the application to such apparatus of an elastic valve of peculiar construction as a substitute for the arrangement now in use. Second, in means of regulating the pressure of the water in the pipes, which is also applicable for regulating the flow of water in other cases. Third, in the application to water-closets generally of means of separating the solid and liquid matters in the basin itself. Fourth, in the application of a cock for regulating the pressure of the water from the mains which also regulates the supply to the basin.—Patent completed.

2622 F. H. VARLEY. *Improvements in apparatus for testing telegraph conductors, part of the invention being applicable to other purposes.* Dated September 18, 1867.

This invention is not described apart from the drawings.—Patent completed.

Digitized by Google

2623 W. W. BURDON. *A new or improved process of bleaching fibre.* Dated September 18, 1867.

Here the patentee first takes the fibre or material to be operated on, and dries it well by artificial heat; he boils the soft material and reduces the hard to shavings; he then puts it into a caustic alkaline solution, and boils; he next washes it well from all impurities, and exposes it to the light; he then puts it into a solution of chloride of lime, or a solution of lime and water, and allows it to remain some time. Next he adds sulphuric acid, or hydrochloric acid, and lets it steep, then washes and exposes it to the air on a floor, or on the grass; he then boils again as before and exposes to light; and he washes again and repeats lying in the solution and boiling, and exposes for some time to the air and light; and he uses the sulphate of magnesia, steeping the material in it, and adding sulphuric acid, also nitric acid, and hydrochloric acid, as he finds necessary or convenient.—Patent completed.

2624 C. LITSTER and G. STOREY. *Improvements in looms for weaving.* Dated September 18, 1867.

The documents relating to this invention are with the law officers under objection, and cannot at present be seen.

2625 T. ADAMS and G. J. PARSON. *Improvements in, and applicable to, slide valves.* Dated September 18, 1867.

This invention has for its object the formation of steam-tight joints applied to the working surfaces of slide valves, and consists in the adaptation and application of metallic packing rings to the steam displacement rings, or to the seating of the valve, or to the valve itself.—Patent completed.

2626 J. SOAMES. *An improved candle fixer.* Dated September 18, 1867.

This candle-fixer consists of a metal button or disc of a suitable diameter, with a shank or pin on its under side, and having on its upper side or face claws or angular and tapered prongs, of which there may be three or more, of any convenient height, projecting upwards, for receiving and holding the lower end of the candle. To the shank or pin projecting from the under side of the button or disc a spring is fixed. This spring is made of suitable dimensions to be received into the socket of a candlestick, according to its diameter, and the size of the candle to be used, and by the expansion of the spring firmly secures the candle and candle-fixer.—Patent abandoned.

2627 T. B. WILKINSON. *Improvements in apparatus for crushing beans, oats, and other grain or seed.* Dated September 18, 1867.

Here, at the lower end of a hopper (into which the grain or seed to be crushed is placed) is an outlet case or trough, in which are enclosed two serrated surfaces, between which the grain or seed must pass as it leaves the hopper. One of these serrated surfaces is formed on a flat plate, which, by a weighed hand lever on the outside, can have a vertical to-and-fro motion imparted to it. The other serrated surface, which may be somewhat curved, is carried by and can be turned on a centre or pin at its upper end, and the lower end of this serrated plate is acted on at the back by a screw in such manner that it can be set to or from the lower end of the moving plate.—Patent abandoned.

2628 H. M. MELLOR. *Improvements in circular knitting frames.* Dated September 18, 1867.

This invention relates to arranging that class of circular knitting frames in which a circle of fixed needles is employed, in such manner as to produce work with a tuck, rib, or seam down it from end to end, so that the work may more nearly resemble that produced on a flat frame, and also arranging such knitting frames so that they may produce ribbed work. The details of this invention are too voluminous to be quoted here.—Patent completed.

2629 R. WATSON. *Improvements in apparatus for distributing gas for heating and lighting.* Dated September 19, 1867.

Here the inventor erects at or in communication with gasworks a strong metallic vessel, called by him the container. By a pump (or a series of pumps), the one delivering into the other, or by water pressure or other means, he forces or compresses gas in the container, and maintains a high pressure therein. A number of taps or valves are fitted into the container through which the high pressure gas is delivered into portable vessels, called by the inventor the distilling vessels. The distributing vessels are those which are filled from the container and are carried to the places where the gas is required; they are made of metal of a cylindrical or other suitable shape, and are provided with taps of valves and connections corresponding to those on the container, so that they can be easily and quickly coupled on to and disconnected therefrom. Lamps to which the said distributing vessels are connected at the place where the gas is to be burnt, or the said vessels themselves, are fitted with means for controlling or cutting down the pressure to a proper burning point, and such means consist in fitting into a small vessel in the delivery pipe, or in an enlarged part of the delivery pipe, sponge or other porous and compressive material. The gas in its passage to the burner, by first coming into contact with one side of the said sponge or other material, compresses it and reduces the area of the openings therein, more or less in proportion to the pressure, and so allows at all times only the required quantity to pass to make proper combustion.—Patent abandoned.

2630 T. C. CLARKSON. *Improvements in the manufacture of ammunition boxes, pontoons, baggage waggons, and various equipments for civil, military, and naval purposes.* Dated September 19, 1867.

The extreme length of this specification prevents our quoting it here at sufficient length for an intelligible abstract.—Patent abandoned.

2631 P. PORTER. *An improved map, blind, scene, and picture roller.* Dated September 19, 1867.

This picture roller, &c., consists of an upper frame or moulding of twice the usual breadth to admit of rolling or folding lengthways, and parallel to this frame is attached a roller turning on its axis, supported at the ends, and leaving room for the map, scene, or picture to move easily up and down between the roller and the upper frame or moulding. The maps, pictures, scenes, or blinds are provided with a roller at each end, and being reversed they may each be respectively exhibited while the upper frame remains in position by means of a cord attached to each roller in the centre, by which they may be elevated or depressed at pleasure.—Patent abandoned.

2632 J. RUST. *A new or improved material for decorative purposes.* Dated September 19, 1867.

The patentee claims the manufacture of a new or improved material applicable for decorative purposes by melting glass and sand, or other earthy matter, together in a crucible or furnace, with the addition of metallic oxides or other colouring matters, and moulding or casting the same into the requisite forms.—Patent completed.

2633 W. J. MURPHY. *Improvements in the method of, and apparatus for, obtaining and applying motive power.* Dated September 19, 1867.

This invention relates to the application of hydrostatic pressure, and also atmospheric pressure, as a motive power. The inventor proposes as a mode of propelling ships or vessels (by means of the hydrostatic pressure produced by their own displacement) that, in the hold or bottom part of every such ship or vessel, there shall be fitted a large tube or cylindrical vessel curved into a semicircle, so that the two ends both project forwards, the curved tube or vessel being filled with water, and the ends being elongated and forming straight cylinders in which two solid pistons are inserted, the outer ends of the rods of such pistons being furnished with heads which bear against strong transverse beams suitably fixed in the hold or bottom of the vessel. In the centre of the semicircular part of the cylindrical vessel or tube a small injection pipe is to be fitted, having a plunger working therein. The other or larger end of the plunger is to be fitted into a shorter cylinder open at both ends and surrounded by the water at the stern. By this means the pressure produced by the displacement of the water by the vessel acts upon the piston end of the plunger, throwing the force of the pressure upon the smaller end of the plunger working in the injector, and consequently the hydrostatic pressure thus created forces the two piston heads against the transverse beams, thus causing the ship or vessel in effect to act as a piston in a cylinder of water, and propelling it by an external pressure in the same manner as the wind acts upon sails.—Patent abandoned

2634 J. HUGGINS. *A polarizing kaleidoscope.* Dated September 19, 1867.

This invention consists in a combination of apparatus whereby the varied changes of pattern produced by the well-known instrument termed the "kaleidoscope" are viewed by means of polarized light.—Patent abandoned.

2635 W. MOLINEAUX. *Improvements in machinery for rolling bars, rods, and plates of iron, steel, and other metals.* Dated September 19, 1867.

This invention consists of an arrangement of parts for acting upon the upper roll of a pair of rolls so as to lower the said upper roll to the required extent, and at the required time, to produce the desired taper or varying thickness, or irregular figure, in the bar, rod, or plate passing through the rolls.—Patent abandoned.

2636 T. BLETCHER. *Improvements in sewing machines.* Dated September 19, 1867.

This invention relates to sewing machines which work with two threads and produce a stitch known as the "lock stitch." The improvement consists, chiefly, in the novel construction, arrangement, and combination of devices for forming the stitches, and in the mechanism for operating the same. The upper thread is carried by a vertically reciprocating needle, and is thereby passed through the cloth or other material in the usual manner. The under thread is carried by a bobbin, which is supported to turn freely upon a pin or rod enclosed in a case or holder. The latter is somewhat similar in form to the flying shuttle employed in other sewing machines, but instead of being caused to move through the loops of needle thread, the holder remains stationary while the successive loops of thread are passed over it by means of a vibrating hook of particular formation, and a lever with elastic arms. The hook places the loop upon the point of the bobbin case, and the elastic lever draws the loop upward between the case and its support, and tightens the thread as each stitch is formed.—Patent completed.

2637 J. G. WILLANS. *Improvements in the manufacture of iron.* Dated September 19, 1867.

The patentee claims forming a mixture of manganiferous iron ore and such coal or other carbon as will cause it to cohere at a red heat, the carbon being in excess of the quantity required for combining with the oxygen in the ore, but insufficient to afford by blast the requisite heat for melting it after its reduction, and the smelting such mixture by other fuel in blast furnaces so as to obtain spiegeleisen or similar compound of manganese, carbon, and iron therefrom, as described.—Patent completed,

2638 H. FISHER. *Improvements applicable to steam boiler and other furnaces.* Dated September 19, 1867.

This invention relates to a former patent, granted to Mr. J. Fisher, dated December 26, 1865 (No. 3338), and one of the main objects of the invention is to prevent, as far as possible, the destruction of the materials forming the furnace. When applied to the furnaces described in the specification of Mr. J. Fisher's patent, the invention consists in the form of hollow brick fuel rests or tubes for the upper tier thereof, whereby the midfeather support may be in some cases dispensed with; and also in the form of the fuel rests when used as water passages. The details of the invention are voluminous.—Patent abandoned.

2639 J. H. SAMS. *Improvements in drill sowing machines, in horse rakes, and in horse hoes.* Dated September 19, 1867.

We cannot here give space to the details of this invention.—Patent completed.

2640 W. W. GIBSON. *Improvements in decorticating and cleaning cereals, and in the machinery or apparatus employed therefor.* Dated September 20, 1867.

This apparatus consists of a revolving drum which may be made either of wood or metal. On the surface of this drum blades or strips of glass, porcelain, common clay, &c., are fixed. The drum is situated within a chamber in which the grain to be decorticated is placed, the sides of the chamber being composed of wire gauze. The grain to be cleaned and decorticated is fed into the apparatus from a hopper at the top, and as it passes between the surface of the revolving drum and wire gauze casing the triturating or rubbing action to which it is thus submitted causes it to be decorticated and cleaned, and the husks and cleanings are blown out through the meshes of the wire gauze covering. In place of forming the casing entirely of wire gauze, it may be partly formed of chambers containing glass, porcelain, clay, or pottery ware strips, the strips being fixed in a manner similar to that by which they are held in the drum. The decorticated and cleaned grain passes out through a spout at the bottom of the case.—Patent completed.

2641 W. POTTS. *Improvements in apparatus for ventilating rooms and buildings.* Dated September 20, 1867.

The patentee claims constructing and arranging in the cornices of rooms and buildings, or at the highest convenient part of the room or building, two independent or separate channels, situated at different levels, the upper one serving to collect and remove the hot and vitiated air from the room or building, and the lower one serving to introduce cool and pure air into the room or building, the hot and vitiated air entering its channel, and the cool and pure air passing from its channel through ornamental or other perforations or wire gauze, as described.—Patent completed.

2642 J. J. and E. HARRISON. *Improvements in carding engines.* Dated September 20, 1867.

This invention relates to that part of the carding engine called the doffer, and consists in improved modes of removing the fleece from the doffing cylinder. Instead of the ordinary doffing comb worked by mechanical movements, the inventors employ a draught of air directed obliquely or tangentially against the card of the doffing cylinder, either inside, or so as to part the fleece from the card, and allow it to be delivered in the usual manner.—Patent abandoned.

2643 L. LENZBERG. *Improvements in gas lamps and burners for the same.* Dated September 20, 1867.

This invention has for its object increasing the illuminating power of gas in outside and inside gas lamps, and consists, first, in adapting to gas lamps a reflector similar to that used in "sunlights" of metal or earthenware, enamelled, silvered, painted or glazed, or prepared with any other suitably reflecting surface, and of a conical, hemispherical, or other suitable shape, in combination with the ordinary sunlight burner, or with the improved burner described in the specification. Second, the invention consists in an improved burner. The reflector and burner are placed inside the lamp frame, one or more openings being left in the reflector for the escape of heated air. Spaces or openings are left or made around the lamp frame to form a current for carrying off the heated air, and for cooling the reflector. The lamp frame is so constructed that its top or bottom is removable, or movable on hinges, to permit of cleaning or repairs.—Patent completed.

2644 A. M. CLARK. *Improvements in the means of tinting or colouring artificial flowers and foliage.* (A communication.) Dated September 20, 1867.

Here the inventor applies the colours by the aid of chromo-lithography, by which means he obtains the desired result in a speedy and economical and more perfect manner than hitherto, mineral colours being employed instead of vegetable, which are infinitely more expensive.—Patent abandoned.

2645 F. T. M. A. GUYON. *A typographic fixiform.* Dated September 20, 1867.

This invention is not described without reference to the drawings.—Patent completed.

2646 C. M'DERMOTT. *An improved slate sponge.* Dated September 20, 1867.

This invention consists of an india-rubber hollow ball, and a piece of sponge, the sponge being attached to the ball by an aperture in the rubber into which a corner of the sponge is fixed. If the air be pressed from the ball, and the ball then dipped into water, it will fill immediately, and the sponge can be moistened from time to time, as may be required, by a slight pressure of the ball.—Patent abandoned.

2647 C. M'DERMOTT. *An improved metallic seal for envelopes.* (A communication.) Dated September 20, 1867.

Here the inventor employs, first, an eyelet of the ordinary shape and size, but having a brim or head of about the size of a threepenny piece. At the edge of this brim are two small prongs at an equal distance from each other, and bent parallel with the eyelet. Second, a round piece of metal of about the size of a threepenny piece, having a hole in the centre of the diameter of the eyelet above alluded to. At the edge of this metal are two prongs, at an equal distance from each other, and bent at right angles to the body of the metal. In applying this contrivance to an envelope, the brim of the eyelet is fastened to the inner flap of the envelope by the two prongs, which are pressed through the paper, and clenched on the reverse side. The round piece of metal is fastened to the outer or gummed flap by the prongs in a similar way, the hole in the centre of the metal being carried through the paper. When the envelope is closed, the eyelet comes through the outer flap, and the metal attached to it, and is then clenched or bent down.—Patent abandoned.

2648 J. G. TONGUE. *Improvements in the preparation of oil for illuminating or other purposes, and in the construction of the lamps employed for burning the same.* (A communication.) Dated September 20, 1867.

This oil is composed of two parts, or thereabouts, of highly refined rape oil, and one part, or thereabouts, of a product resulting from the distillation of petroleum or mineral oil. Lamps constructed in accordance with the second part of these improvements may be constructed so as to have the appearance of ordinary moderator lamps, although the form of such lamps may be greatly varied. The outer wick tube of the burner of a lamp constructed for burning oil of the above description, a short distance below the point at which the wick burns, is perforated with a series of small holes, so that when the oil rises to this point, it flows through the holes into an annular space formed by another tube which surrounds the wick tube, by which means any excess of oil is re-conducted to the oil reservoir.—Patent abandoned.

2649 R. RAFFAULT. *An improved petticoat.* Dated September 20, 1867.

This invention consists in providing plaits, folds, creases, or gatherings in suitable parts of petticoats, with the object that the said plaits, folds, creases, or gatherings in expanding should offer room for the knees or other protuberant parts of the body of the wearer when sitting or stooping down, or reclining, and which plaits, folds, creases, or gatherings may afterwards resume their original shape, so as not to alter the general appearance of the petticoat.—Patent completed.

2650 S. DREYFOUS. *Improvements in bread ovens, and in their combination with various apparatus for the manufacture of bread.* (A communication.) Dated September 20, 1867.

This invention consists in combining the fireplace for the boiler of a steam engine with a bread oven or ovens, in order that the oven or ovens, and the boiler, may be heated simultaneously by the heat arising from the fuel of the fireplace, whilst the engine serves for working a kneading machine, or other suitable apparatus, subservient in bread making.—Patent completed.

Digitized by Google

2651 E. H. NEWBY. *An improved alarm apparatus.* Dated September 20, 1867.

This invention relates to an apparatus which is chiefly designed for temporary attachment during the night to the door or window of a bedroom, to indicate any attempt made to open the said door or window. The apparatus gives warning by means of a bell, which, by the action of a simple arrangement of clockwork, is caused to ring violently when a vibrating hammer or striker is released from a catch or stop.—Patent abandoned.

2652 W. HALL. *Improvements in separating yeast from liquid matters.* Dated September 20, 1867.

The documents relating to this invention cannot at present be seen.

2653 W. E. NEWTON. *Improvements in whips and whip holders.* (A communication.) Dated September 20, 1867.

This invention consists in making the whip tubular at its butt end, so that it may be held in an upright position upon a suitable stem or holder. The invention further consists in a stem or holder formed of metal, which is attached to any convenient part of the vehicle, and serves to sustain the whip when it is provided with a tubular butt, as hereinbefore mentioned. The invention further consists in the combination of a stem or holder with a whip formed with a tubular butt, whereby the efficient operation of the principal features hereinbefore indicated is secured. The invention further consists in constructing the loading at the butt of the whip in the form of a socket, so that no additional expense is involved in making the butt of the required tubular form, at the same time that the surface around the socket, being hard and smooth, no wearing away of the same is liable to occur. The invention further consists in certain means whereby the more secure retention of the whip upon the holder is obtained. —Patent completed.

2654 C. E. and J. GREEN. *A new or improved cartridge for breech-loading firearms.* Dated September 21, 1867.

Here the cartridge is shot out direct from the barrel of the gun, no metallic case being required. The inventors construct the case in the usual way, but prefer using waterproof paper; they then place a small portion of detonating powder between two or more pieces of pasteboard, which pieces of pasteboard are perforated and pressed down upon the powder; upon this pasteboard a layer or layers of vulcanized india-rubber is or are placed, through which the pin or striker of the breech apparatus penetrates the cartridge at its base, thus causing the explosion. With this cartridge no extractor is required.—Patent abandoned.

2655 P. CRAUSE. *Improvements in ventilators for hats and other coverings for the head.* Dated September 21, 1867.

This invention consists in the adaptation and application to a hat of a concave ring of thin sheet metal of about 1¼in. to 2in. internal diameter, so placed as to cover apertures formed in the hat, the inner end of such ring being fixed to the hat, and a space being left between the outer edge of the ring and the hat. By this means the air entering through the apertures, instead of passing directly on to the head, as usual, would be deflected and diffused by escaping at the space between the outer edge of the ring and the hat.—Patent abandoned.

2656 G. E. MARCHISIO. *Improvements in the treatment of the residuum which results from the purification of cotton seed oil, and of the residuum which results from the distillation of the said material, for the manufacture of isolating, preservative, and anti-corrosive compositions.* Dated September 21, 1867.

The patentee claims, first, the methods of treating the "foots" or residuum which results from the clarification and purification of cotton seed oil, and also of treating the residuum which results from the distillation, evaporation, or other analagous treating of foots, and the production therefrom of a composition in a liquid, semi-liquid, or solid state, applicable for the various purposes mentioned, substantially as set forth and described. Second, the manufacture and preparation of isolating preservative and anti-corrosive compositions, substantially as described and set forth, or any mere modifications thereof.—Patent completed.

2657 J. HARGREAVES. *Improvements in the manufacture of iron.* Dated September 21, 1867.

This invention has reference to a previous patent, dated August 22, 1867 (No. 2407), and relates to the use of a solution of chloride of manganese for separating shale and pyrites from coal. The patentee claims the use or employment of chloride of manganese, substantially in the manner and for the purpose set forth.—Patent completed.

2658 D. HOWARD. *Certain improvements in the manufacture of fabrics termed union flannels, and in other similar union fabrics.* Dated September 21, 1867.

This invention consists, first, in the employment and use of a warp composed of wool and silk, wool and cotton, or wool, cotton, silk, and China grass, or wool and any other fibrous substance which will mix with wool. Second, in the use of a weft composed of cotton alone, or cotton and flax, or cotton and silk, or cotton, flax, silk, and China grass, or the whole combined, or cotton and any other vegetable fibrous substances.—Patent abandoned.

2659 J. S. WILLIAMSON. *Drying, cleaning, and separating grain.* Dated September 21, 1867.

This invention is not described apart from the drawings —Patent abandoned.

2660 A. L. DICKINS and H. HEYWOOD. *Improvements in printing yarns or threads.* Dated September 21, 1867.

This invention consists in printing yarns or threads by passing hanks thereof between rollers, such hanks being held parallel to the axes of the said rollers. These rollers are provided with projecting rings, or other suitable parts, disposed along the rollers at intervals, according to the design intended to be produced, and when more than one colour is desired, they use two or more colour boxes provided with rollers for conveying the colours, and with projecting rings or parts corresponding to those upon the printing roller to which a particular colour is appropriated. —Patent abandoned.

2661 D. T. LEE. *Improvements in the application or combination of animal with vegetable food.* Dated September 21, 1867.

This invention consists in combining extract of meat of any description, in any proportion, and prepared in any suitable manner, but, by preference, upon Liebig's formula, with flour, meal, bran, cocoa, sugar, or other edible vegetable product, and then preparing, cooking, or otherwise treating the compound in the form of biscuits, cakes, sweetmeats, or any other form in which it may be adapted for consumption.—Patent abandoned.

2662 B. and A. B. BLACKBURN. *Improvements in lucifer matches or tapers, and in the apparatus for holding and igniting the same.* Dated September 21, 1867.

This invention has for its object to produce a lighted taper or match which will burn sufficiently long (say) five or ten minutes, to admit of sealing two, three, or more letters or parcels. To this end the invention consists, first, in employing short lengths of wax taper or wax matches, provided at one end with an igniting composition, which will ignite upon the application of friction. The opposite ends of these short lengths are inserted in a solid combustible composition, such as wax, tallow, or stearine, which is contained in a small or shallow cup. When this composition is cold, it becomes solid and hard, and it will firmly hold the match in place. Any convenient number of these small cups are to be fixed on a piece of cardboard, wood, clay, &c., so arranged that the matches or tapers may be brought in succession against a projecting hard substance, by rubbing against which their prepared ends will be ignited by the friction.—Patent completed.

2663 J. MEIKLEJON. *Improvements in machinery or apparatus for lifting, lowering, and transporting heavy bodies.* Dated September 21, 1867.

This invention is carried out as follows:—At the entrance, one end, or other convenient part of the building, a wheel is placed, centrally, or thereabouts, between the adjacent sides. An endless chain or band passes over the wheel, by pulling which the wheel is actuated. On the same axis as that to which the wheel is placed there is attached a drum, the periphery of which is formed to receive the links of a chain, the two ends of the chain being passed thence over pulleys, and downwards through guide eyes at each side of the building. To each end of the chain a hook is attached for holding the body or bodies to be lifted. On either side of the building in which the hoisting apparatus is erected angle, T, or channel iron guides are placed, upon each of which a travelling carriage is placed, and which is provided with hooks, so that when it is desired to transport a body it is raised, by the lifting gear, and attached to one or more hooks, on one of the travelling carriages, and when so placed the transportation is easily effected by an attendant pushing the carriage along the guides to the place desired, after which the body or bodies may be detached and lowered by means similar to that used for raising it, or by other lowering arrangement at present in use.—Patent abandoned.

2664 J. BAIRD. *Improvements in the treatment of jute, and in oils or preparations for softening the fibres thereof.* Dated September 21, 1867.

This invention has for its object the dispensing either wholly or partially with the use of fish oils, such as whale, seal, or cod oil, which have hitherto almost exclusively been employed in the treatment or preparation of jute for the purpose of softening the fibres thereof prior to its manufacture. These fish oils are not only in some cases expensive, but frequently their use is objectionable by reason of the excess of fibrinous or mucous matter which they contain, and which, though necessary to a certain extent, will, when in excess, tend to clog the fibres, and the machinery operating thereon Now, according to one part of this invention, the patentee proposes to dispense entirely with the use of fish oils, and to employ in lieu thereof any of those fatty oils (such, for example, as olein, lard oil, rape oil, olive oil, cotton oil) which are free, or comparatively free, from dissolved fibrine, such fatty oils being either employed separately or in mixtures of any two or more of them.—Patent completed.

2665 A. MACKENSIE and S. ROBINSON. *Improvements in apparatus to be applied to cisterns for preventing waste of water.* Dated September 21, 1867.

In applying this invention to water-closet cisterns, for example, the patentees construct inside the cistern, at the lowest part thereof, a gauge chamber of sufficient capacity to contain the requisite amount of water for one flushing of the closet. A small aperture is made in the side of this chamber at the bottom for filling the same from the surrounding water in the cistern, such aperture being opened by the act of closing the principal valve of the cistern, and closed when such valve is opened, a small inlet valve being employed for that purpose adapted to the aperture referred to. At the bottom of the gauge chamber there is fitted the valve-seat and valve, opening either into the old service box, or into a supply pipe leading direct to the basin. This valve is provided with a tubular spindle, having a piston, being connected to a float inside the closed chamber before referred to, and on the lower part of the piston is formed a valve cap, and on the upper part of the tubular spindle through which the piston works there is formed a valve seat, so that, when the piston is raised by the float to a given height, the second passage for water (namely, the passage through the tubular spindle) is closed, and remains closed until, by the opening of the principal valve, the chamber is emptied. This piston is further coupled by a wire to the usual overhead weighted lever which is connected to the "pull" or handle of the closet. The object of the entire arrangement is, first, to admit the full complement of water in the closed chamber to pass down through the principal valve when opened; and, second, to permit of a certain gauged or regulated quantity of water sufficient to fill the pan of the closet to descend through the tubular spindle of the main valve after it has been closed. This latter is the result of the quantity of water admitted to flow through the small open aperture being in a certain proportion in excess of the quantity which can pass down through the tubular spindle or piston valve, and, consequently, the chamber will in a short time become nearly full, and the float raised so as to close the inner valve. This float, however, is not sufficiently buoyant to open the principal valve.—Patent completed.

2666 D. SCULL. *Improvements in the treatment of xyloidine.* Dated September 21, 1867.

This invention consists in the substitution for such dehydrated spirit or naphtha of alcohol which has not been subjected to the process of dehydration, in conjunction with, and in combination with, certain substances and compounds mentioned in the specification, which substances and compounds are soluble therein, and which are insoluble, or nearly so, in water, such, for example, as fixed oils, vegetable oils, essential oils, resins, gum-resins, spirits of turpentine, fats, light oils, and naphtha from coal, and mineral naphthas, and the patentee employs such substances, or mixtures of the same, in such proportion, as that, although the substances individually possess but little, if any, solvent action on the hydrated xyloidine, they shall, by suitable admixture with alcohol, be rendered solvents of the same.—Patent abandoned.

2667 T. MUIR. *Improvements in washing rollers and blankets used by printers, and in the machinery or apparatus employed therefor.* Dated September 21, 1867.

Here the rollers to be washed are placed with their journals resting in brackets projecting upwards from a trough. In the trough a large revolving can or drum is placed, the can or drum being covered with blanket. The rollers to be washed are so disposed that, when placed on the blankets, their surfaces rest or bear upon the flannel-covered surface of the large revolving can or drum, and when the latter is revolved, its frictional contact with the printing rollers causes them also to revolve. Across the top of the washing machine a perforated pipe extends, and it is connected at the centre, or thereabouts, with a vessel or reservoir containing the washing fluid, which, as the machine is in action, drops through the perforations on to the rollers, and these being rubbed by the action of the blanket on their surfaces during the time that the washing liquid is falling, causes the ink and other matter adhering to them to be removed. The washing is finished by running clean water over the rollers after the washing liquid has been used.—Patent completed.

2668 A. AITCHISON and H. J. GRANTHAM. *Improvement in the production of carburetted gas, and in the apparatus and burner applicable thereto.* Dated September 21, 1867.

The patentees claim the method of carburetting gas by causing the same to pass into a globe or vessel containing any suitable hydrocarbon saturated in conjunction with sponge, or other absorbent materials, whereby the traverse or passage of the gas through the globe to the burner causes it to take up a sufficient quantity of hydrocarbon vapour to carburet the gas and increase its illuminating power; and also the apparatus employed therein, substantially as specified.—Patent completed.

2669 J. RIVES. *Improvements in the manufacture of metallic pens.* Dated September 21, 1867.

The first part of this invention has for its object the hardening of the points of metallic pens to render them more durable. For this purpose, after the pens have been tempered and split in the ordinary manner, the patentee places around the points of each pen a small bead or collar of copper (or other metal that is a good conductor of heat); he then heats the point in a flame, or by a blow-pipe, and plunges it either into water or oil, or otherwise cools it rapidly; by this means the points of the pens may be so hardened that they will even cut glass.—Patent completed.

2670 S. C. LISTER. *Improvements in furnaces.* Dated September 21, 1867.

This invention relates to a previous patent, dated July 17, 1867 (No. 2099), and has for one of its objects the supplying air to the gases and vapours as they arise from the surface of fuel on the firebars of a furnace. This he effects by forcing air by mechanical means into the furnace through perforations in chambers or pipes placed along the sides, or it might be along the centre, or at other points of a furnace; the perforations being above the surface of the fuel, a very intimate mixture of air and gases is thus obtained, by which combustion is facilitated, and so a saving of fuel is effected.—Patent abandoned.

2671 T. KENDRICK. *Improvements in self-acting folding carriage steps.* Dated September 21, 1867.

The connecting rod or lever which is acted upon by the carriage door, and by which the steps are unfolded and folded up, is, in the ordinary arrangement, connected to the side bars of the step, and passes through a slot or opening in the top step and back vertical plate. By this lateral connection the carriage door is subjected to much strain, and the object of this invention is to reduce the said strain to a minimum by so arranging the folding and unfolding mechanism as to cause it to act upon the steps centrally instead of at the side, as is usual.—Patent abandoned.

2672 J. R. COOPER. *Improvements in firearms.* Dated September 21, 1867.

This invention has for its object the prevention of the accidental discharge of firearms, and consists of the adaptation or use of a bolt or pin made to pass transversely through or bear against such part or parts of the firearm as will cause the said bolt or pin to fix the hammer, or to fix such other part of the firearm as will prevent the discharge of the firearm.—Patent completed.

2673 G. W. MCGEORGE. *Improvements in pipes for smoking* Dated September 23, 1867.

This invention consists in the adoption of an outer bowl, as usual, and a partition or partition bowl or receptacle for the oils disengaged in smoking (the same being provided with an aperture or apertures for the smoke), and an inner bowl for containing the substance to be used for smoking, also provided with an aperture or apertures for the smoke, as set forth, whereby the disengaged oils are deposited in the partition bowl or receptacle, and kept separated from any saliva from the mouth which may find its way into the stem or outer bowl. —Patent completed.

2674 C. RITCHIE. *Improvements in apparatus for regulating automatically the supply of gas, air, and water, or any one or more of them, to steam boilers heated by gas or otherwise, and for utilizing the heat of the gases produced or heated by combustion.* Dated September 23, 1867.

Here the patentee constructs in, or attaches to, the boiler, at any convenient part thereof, a small cylinder or receptacle, one end of which is in communication with the boiler. Within this cylinder or receptacle is a piston or valve provided with a spiral or other spring of suitable tension or pressure, to which piston or valve, or to its rod, is or are connected in any suitable way a weight or weights which tend to force it downward in the cylinder or receptacle, in opposition to the steam which passes from the boiler into the said cylinder or receptacle. The rod of this piston or valve is connected by a lever and toothed wheels, or in any other convenient way, with (in the case of a boiler heated by gas) the tap or other contrivance which regulates the supply of gas, and also with the tap or other contrivance which regulates the supply of atmospheric air, so that, when there is too great pressure of steam within the boiler, the supply of gas is lessened or cut off, and the supply of air is at the time regulated, as may be required, for the support of combustion, or for cooling down the contents of the boiler, in order that the water may not be prevented by excess of pressure of the steam from entering the boiler from the cistern or any other source of supply that may be used; and also that the pressure of the steam when it becomes too great may be lessened; and that when a damper is used to regulate the

Digitized by Google

air pressing into or from the furnace, this damper may be opened or closed by the piston or valve arrangements above mentioned.—Patent completed.

PROVISIONAL PROTECTIONS.

Dated March 3, 1867.

716 H. P. Reynoldson, Twister's-alley, Bunhill-row, Middlesex, bookbinder. Improvements in portfolios.

Dated March 4, 1868.

736 F. Cadby, Birmingham, cut and engraved glass manufacturer. Improvements in the construction of cruet and egg frames or stands.

Dated March 6, 1867.

772 D. Price, Dudbridge, and C. Rowe, Briscombe, both in Gloucestershire, engineers. Improvements in apparatus for combing or cleaning animals.

Dated March 7, 1868.

789 S. Brown, Blackfriars-road, Surrey, perfumer. An improvement in the method of ornamenting bottles, vases, and jars used for perfume or toilet purposes.

800 W. W. Greener, Loveday-street, Birmingham, gun manufacturer. Improvements in central-fire breech-loading guns and pistols.

Dated March 9, 1868.

807 H. B. Barlow, Manchester. Improvements in machinery for carding, combing, and straightening the fibres of cotton and other fibrous substances. (A communication.)

Dated March 10, 1868.

826 J. Vero, Dewsbury, Yorkshire, hatter. Improvements in machinery or apparatus for the manufacture of hats.

Dated March 12, 1868.

844 J. Bourne, Northumberland-terrace, Regent's Park-road, civil engineer. Improvements in auxiliary propulsion.

Dated March 13, 1868.

857 J. H. Maw, Broseley, Shropshire. Improvements in moderator lamps.

859 A. Taylor, Oak-street, Wolverhampton. Improvements in brakes or apparatus to control the rotation of an axis.

Dated March 16, 1868.

893 J. Murray, Westgate-street, Newcastle-upon-Tyne, merchant, and R. Warden, Ellison-street, Gateshead, brass finisher. Improvements in lamps for burning paraffin and other oils and spirit.

Dated March 17, 1868.

898 R. Smith, Compton-road, Islington. Improvements in the means and apparatus for extracting foul air or gases from mines, sewers, brewers' vats, and other places.

900 C. Womersley, Saltaire, Yorkshire. An improved lubricator.

902 Sir J. Macneill, Cockspur-street, Charing Cross. Improvements in the construction of indicating apparatus for showing the number of passengers carried in public conveyances during each journey, and the amount of fares paid.

903 P. M. Villamil, Coleshill-street, Eaton-square, Middlesex, artist. Improved apparatus to facilitate the ascending of gradients by locomotive engines.

905 W. R. Lake, Southampton-buildings, Chancery-lane. An improved substitute for hair stuffing, and mode of manufacturing the same from vegetables fibres. (A communication.)

906 J. M. Poisnel, Rue Hauteville, Paris, manufacturer. Improvements in the manufacture of straps, belts, bands, pipes, and other articles of india-rubber or similar fabric.

907 J. Thompson, Manor House, Camberwell-road, and J. Thompson, Camberwell Green, Surrey. Improvements in machinery for shaping wood, applicable especially for producing spokes for wheels.

908 J. M. Poisnel, Rue Hauteville, Paris, manufacturer. Improvements in the manufacture of coverings for the feet.

909 W. E. Newton, Chancery-lane. Improvements in producing steel and cast steel, and in furnaces used therein. (A communication.)

911 W. E. Newton, Chancery-lane. An improved apparatus for measuring and administering medicine. (A communication.)

912 J. F. Spencer, Sunderland. Improvements in working the valves of steam and other engines.

Dated March 18, 1868.

913 J. M. Ure, Glasgow, engineer. Improved apparatus for lifting the driving wheels of a locomotive off the rails when the locomotive is either running or stationary.

914 W. Sinale, Macclesfield, Chester. Improved machinery or apparatus for figure weaving, in combination with a jacquard loom.

915 C. F. C. Cretin Borne, Glasgow. Improved means or apparatus for ventilating or supplying air to mines and other places.

917 E. Butterworth, Calder Cottage, near Rochdale, Lancashire, machinist. Improvements in furnaces or fireplaces.

918 W. R. Lake, Southampton-buildings, Chancery-lane. An improved mode of, and apparatus for, effecting the continuous return into a steam boiler of the water evaporated and taken from the same. (A communication.)

919 G. Martin, Toads-moor Mills, near Stroud, Gloucestershire. Improvements in the treatment of mixed fabrics, and in the extraction of wool therefrom, and in the construction of apparatus to be used for such treatment, which apparatus is also applicable to other purposes.

920 A. V. Newton, Chancery-lane. An improved manufacture of covering for floors. (A communication.)

923 B. E. R. Newlands, F.C.S., Malvern-terrace, Charlton, Kent. Improvements in treating and obtaining products from spent oxide of iron which has been used in gas works or otherwise, to separate sulphur from sulphuretted hydrogen, and in the purification of sulphur obtained from such oxide of iron.

924 R. A. Wright, Homerton, Middlesex, engineer. Improvements in the mode of, and apparatus for, cutting and dressing millstones and other stones.

925 J. B. Linnett, Birmingham, printer. Improvements in the means of producing optical illusions.

926 G. Wailes, Stroud, Gloucestershire, engineer. Improvements in the manufacture of safes or strong boxes.

Dated March 19, 1868.

928 P. Hill, Leinster-square, Middlesex. Improvements in brakes for perambulators and other vehicles propelled by hand.

929 B. Parks, Lewisham, Kent. Improvements in machinery or apparatus for separating and crushing breeze or cinders in one combined action.

931 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in ventilating windows and window blinds. (A communication.)

932 J. Edwards, Wednesbury, Staffordshire, manufacturer. Improvements in props or supports for supporting the roofs of coal or other mines.

933 W. Redman, Bankfoot, Hebden Bridge, Yorkshire, self-acting minder. Improvements in means or apparatus for the formation or building of cop bottoms in machinery for spinning and twisting cotton or other fibrous substances.

934 E. Rowland, engineer, and J. Dalton, Manchester. Certain improvements in the method and arrangement of apparatus for closing dampers, which apparatus may also be employed for measuring liquids.

935 G. Davis, Serle-street, Lincoln's Inn. Improvements in machinery for combing cotton and other fibres. (A communication.)

937 W. Richardson, Oldham, Lancashire. Improvements in machinery for the manufacture of bricks and tiles.

938 F. Warner, Jewin-crescent, City, engineer, and H. Chopping, Roxwell, Essex. Improvements in windmills.

939 W. Hooper, Mitcham, Surrey. Improvements in treating india-rubber, and in the manufacture therefrom of fabrics and of insulated telegraphic conductors.

940 J. L. Geiger, Great Winchester-street-buildings, City. Improvements in doubling, twisting, and throwing silk, and in apparatus therefor. (A communication.)

942 L. Encausse, Madrid, Spain, chemist. Improvements in the application of remedial agents to the human frame, and in the apparatus employed therein.

943 H. Chamberlain and J. Craven, Wakefield, Yorkshire, engineers, and H. Wedekind, Dunster-court, Mincing-lane, City, engineer. Improvements in the burning and drying of bricks, lime, cement, and other like substances, and in the kilns employed therein. (Partly a communication.)

Dated March 20, 1868.

945 R. Side, Southwark Bridge-road, Southwark. A compound lever, introducing gravitation as a motive power to supersede a considerable amount of steam power.

947 C. Mather, Salford, Lancashire, engineer. Improvements in machinery and apparatus for opening and cleaning wool and other fibrous substances. (A communication.)

949 R. Meldrum, Pittormie, Cupar, Fifeshire. Improvements in steam engines.

950 A. Brownlie, Wishaw, Lanarkshire. Improvements in apparatus for heating air for grain kilns.

952 J. Abraham and T. R. Bayliss, Birmingham, machinists. Improvements in central-fire cartridges for breech-loading firearms.

953 J. H. Cooper, Regent-street, bootmakers. Improvements in the manufacture of boots for hunting, shooting, fishing, and other uses.

954 C. Gunner, Lucas-road, Kennington. Improvements in lifeboats.

955 J. H. C. Bade, Dalston, Middlesex, engineer. Improvements in close fire ranges.

956 G. Twigg, Birmingham, manufacturer, and H. Bateman, Barnes, Surrey, architect. Improvements in the manufacture of corkscrews.

957 S. Duer, Harewood-square, Middlesex, engineer. Improvements in the manufacture of packing for stuffing boxes, pistons, and bearings. (Partly a communication.)

Dated March 21, 1868.

958 G. Davies, Serle-street, Lincoln's Inn. Improvements in apparatus to be used in the manufacture of millstones, and in the working of hard stones in general. (A communication.)

959 E. D. Johnson, Wilmington-square, Middlesex. Improvements in the construction of pocket watches.

962 W. S. Boulton, Norwich, manufacturing engineer. Improvements in lawn mowers.

964 W. G. C. Hudson, Barbara-street, Islington. A new or improved sandal or overshoe for preventing slipping in frosty weather and other uses.

966 J. G. Jennings, Palace Wharf, Lambeth, sanitary engineer. Improvements in water-closets, and in apparatus for supplying water, and in sewers or drains for receiving the same.

Dated March 23, 1868.

972 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in metal ties or bands for securing bales of cotton or other substances. (A communication.)

974 C. E. Brooman, Fleet-street, City, patent agent. Improvements in machinery for the manufacture of lace. (A communication.)

976 J. Bronner, Frankfort-on-the-Maine, Prussia, manufacturer. Improvements in the construction of gas burners.

978 G. F. Guy, Bury St. Edmund's, Suffolk. Improvements in the manufacture of sugar and other alimentary substances from beet-root.

980 A. W. Ramsear, Gray's Inn-road, gunsmith, and F. W. Wilson, Edgware-road, Middlesex. Improvements in breech-loading firearms and cartridges.

982 C. de Bergue, Strand, Westminster, engineer. Improvements in locomotive engines, and in the modes of transmitting the power of a locomotive engine to the tender and other carriages of a train, for converting their wheels into driving wheels.

984 A. Barclay, Kilmarnock, Ayrshire. Improvements in barometers and thermometers, and in their combination with watches, clocks, and other instruments.

986 H. Treverton, Duke-street West, Smithfield, City, manufacturer, and E. H. Fowler, Brixton, Surrey, clerk. Improvements in frames or holders for lamp shades or glasses.

PATENT APPLIED FOR WITH COMPLETE SPECIFICATION.

Dated March 30, 1868.

1083 C. S. Tyson, Prince George, Maryland, U.S., engineer. Improved mechanism for taking up the recoil of heavy ordnance.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the "London Gazette," April 7, 1868.

3339 J. P. Smith. Manufacture of cutting tools.
3340 J. P. Smith. Coating metals with metals.
3343 J. A. and J. Hopkinson. Steam boilers.
3347 J. Hudson. Machinery for the manufacture of paper.
3360 H. F. Gardner. Means of treating metals in order to produce their oxides. (A communication.)
3365 M. A. Hamilton. Cutting implement.
3370 E. T. Hughes. Tea and coffee pots. (A communication.)
3371 T. and B. Carter and J. Lisle. Machinery employed in the preparation of wool.
3372 W. Cotton. Machinery for cutting woollen corduroy.
3374 E. T. Hughes. Sprinkler for powdered substances. (A communication.)
3378 J. M. Napier. Vessels for preserving unguents.
3382 J. Scholefield. Covers for umbrellas.
3388 T. Rose and R. E. Gibson. Treating cotton seed.
3391 H. S. Cowan. Apparatus for signalling at sea.
3397 J. J. Parkes. Means of ventilating rooms.
3399 W. E. Gedge. Brake washer. (A communication.)
3409 R. Clay. Breech-loading firearms.
3416 C. and S. Hargrove. Bells.
3428 R. Porter. Constructing metallic buildings.
3432 J. Collingham and T. E. Smith. Steps of spindles for spinning.
3439 W. Brown and C. N. May. Portable steam engines and boilers.
3450 R. R. Gray. Metallic casks.
3462 J. Mabson. Bags for coffee.
3472 J. W. Kenyon and R. A. Armistead. Safety apparatus for steam boilers.
3491 C. M. Barker. Socket and flange spigot pipes.
3515 A. Camme and F. Delpech. Manufacturing iron and steel chains.
3533 J. Collingham and T. E. Smith. Spinning frames.
3552 W. E. Newton. Bench planes.
3553 L. Christophe and J. Montigny. Tubular cannon.
84 W. R. Lake. Cutters for forming wood mouldings. (A communication.)
111 J. H. Johnson. Pipes for smoking. (A communication.)
258 K. J. Winslow. Conveying rotary motion to axles.
493 W. R. Lake. Mode of extracting the volatile portions of ores. (A communication.)
755 F. T. Baker. Manufacture of cartridge cases.
756 J. J. F. Stevens. Railway signal apparatus.
785 J. Houston. Manufacture of composite candles.
846 W. Thompson. Manufacture of iron castings.
871 W. Bellhouse and R. Ashworth. Carding engines.
923 B. E. R. Newlands. Treating products from spent oxide of iron.
1083 C. S. Tyson. Mechanism for taking up the recoil of heavy ordnance.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list, who have given notice of their intention to proceed, within twenty-one days from the date of the "Gazette" in which the notice appears, by leaving at the Commissioners' office, particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed April 4, 1868.

2630 T. C. Clarkson	2841 J. Speight
2805 W. Low and J. Treadwell	2852 A. M. Clark
2808 W. R. Lake	2933 S. S. Maurice
2813 J. Smith	3071 J. Watkins
2822 J. H. Brown	3246 R. Heathfield
2826 J. B. Hulme	3271 K. J. Winslow
2835 A. Danilecki	3352 E. H. Bentall
2840 W. Potts	3651 M. J. Rice

PATENTS ON WHICH THE STAMP DUTY OF £50 HAS BEEN PAID.

924 G. Burt	973 R. Maynard
955 W. E. Newton	986 P. Hugon
958 G. T. Bousfield	1007 G. Davies
962 J. G. N. Alleyne	1058 C. F. Cotterill
971 F. R. Ensor	1700 M. Ashby

PATENTS ON WHICH THE STAMP DUTY OF £100 HAS BEEN PAID.

819 W. and F. W. Crichton	832 A. V. Newton
825 J. G. N. Alleyne	877 F. Ransome

THE

MECHANICS' MAGAZINE.

LONDON: FRIDAY, APRIL 17, 1868.

SCIENCE IN ABYSSINIA.

WHAT a contrast the proceedings of an expeditionary army in the present day offer to those of armies of former times! How science ministers to the health and comfort, and aids the progress, of our troops now to what it did in the Peninsular wars, or even in the later Russian campaign! Contrast the old snail's pace, lumbering, toilsome military tactics with those of our Abyssinian field force, and we need no more to demonstrate the progress of the applied sciences. In the first place, here is an official despatch from the commander of the forces in Abyssinia, dated March 14, detailing the operations of the troops, printed and circulated in London within four weeks of its date. What would our fathers have given for such detailed news in that time from places far nearer London than Abyssinia. But even this rapidity of transit does not satisfy the present age, and people are surprised that Government has not taken steps to organize a special communication with the head quarters of the invading force. A correspondent of the "Times" observes that the importance of such a step is so evident that there must be some insuperable difficulty in the way of its being carried out. The distance from Magdala to Annesley Bay over the roads now practicable is about 250 miles, and this distance the writer referred to presumes could be traversed by horse relays in twenty-four hours. From Annesley Bay to Suez, a distance of 900 geographical miles, a moderately swift steamer would convey a mail in four days, so that in six days a telegraphic message sent on from Suez would convey the news from Magdala to London. Hence, "if a large force of our countrymen has yet to remain for some months in Abyssinia, it would be an unspeakable comfort to receive tidings of them once a week." No doubt it would, and an unspeakable pleasure, too, for those who had to pay for the arrangement.

Turning to the despatch itself, we find it presenting an appearance much more like that of a paper read before one of our scientific societies than of a report from a military general. Railway engineering, telegraphy, photography, well sinking, trigonometry, &c., run in turns with easy cadence throughout its length, and give it an interest to our readers which otherwise it could hardly possess. Taking the above items seriatim, we shall gather from their details the important part science is playing in our military organization and its bearing upon field operations. First, then, the railways. But we recommend our readers to obtain maps of the district before reading further, unless they are not particular as to the exact latitude and longitude of all the queer-named places we shall have to deal with. According to the last report received from the commanding engineer at head quarters, 6 miles and 576 yards of the railway from Zoolla to Koomaylee were completed up to the 26th ult., leaving 5 miles and 1,184 yards still to be made. The report states that many and great difficulties have had to be contended against, from the different descriptions of plant forwarded from India. It states that the rails received from Kurrachee differ in size from those received from Bombay, that many of them are bent, and that the fish plates attached are not bolt drilled in an uniform manner. Knowing the hopeless bemuddlement of railway constructive details in India, we are not in the least surprised to learn this; indeed, we should have elevated our eyebrows had the contrary have been reported. In addition to these difficulties there has been a paucity of skilled workmen, and an insufficient amount of ordinary labour, on account of the number of other works on hand at Zoolla. But orders have been issued for every available man to be put upon this work, and the officers commanding at Zoolla and Senafé have been directed to render every assistance in their power by placing strong working parties at the disposal of the commanding engineer. It is, however, satisfactory to learn that the most difficult part of the line has been completed, and it is hoped that the work will now progress more rapidly.

The telegraph line, we are informed, is completed and in working order to Addigerat, a distance of 101 miles from Zoolla; interruptions, however, constantly occur by breaks in the line, generally supposed to be caused by natives of the country, who steal the wire. The progress of the line onwards towards Antalo is at present delayed for want of poles; none suitable are procurable in the neighbourhood, and the transport animals are so fully employed in carrying up provisions and moving troops that there is a difficulty in bringing any up from Zoolla. The 2nd Company, Bombay Sappers, and 53rd Tent Lascars, have been placed at the disposal of Lieutenant St. John, R.E., director of the telegraph, to assist in putting up posts and laying the line. But as there are no posts to put up there can be no line laid, so the lieutenant and his men may have a merry time of it. We now come to photography and signalling, which matters are, of course, in the hands of the Royal Engineers, the head quarters of the 10th Company of which corps generally march with the head-quarter camp. The photographers have been employed in photographing plans and views, as well as surveys, of the route onwards, prints of which are handed over to the commanding officers of corps previous to the march. Ten non-commissioned officers and men of her Majesty's 33rd Regiment have been instructed in the use of flags, for the purpose of signalling, and the men of the 10th Company, Royal Engineers, have occasionally been practised with the army night signals.

Well sinking is one of the most important operations, and this has been entrusted to Lieutenant Le Messurier, R.E., who, with a party of the 10th Company, Royal Engineers, has been engaged in improving the supply and the arrangements for watering animals at all the posts occupied by our troops, from Koomaylee to the front. The supply of water at Koomaylee, the largest depot on the line, is now reported ample, and is distributed by means of six Norton's tube wells, one Bastier's 2½in. chain pump, one fire-engine, and six dipping wells. Norton's tube well will be found fully described and illustrated at page 216 of the MECHANICS' MAGAZINE, for the 20th ult., and we are glad to find such ample testimony to its merits as the Abyssinian expedition affords. At Upper Sooroo troughs and tubs have been fixed, and 18,000 gallons of water stored by the roadside, and a second road, to lead to the water supply, made to avoid the high road at any time becoming blocked up. A tube well has also been driven which affords pure drinking water, and a separate tank has been reserved for the native Shohos. At Undul the supply is also reported good. One Bastier's 2½in. chain pump has been fixed over a masonry well, 32ft. deep, and two Norton's tube wells driven; troughs and shoots have been erected, to receive the supply from these wells, and one other well has been dug, about 28ft. deep, with an average depth of 4ft. of water in each. At Henderta (half-way between Undul and Raraguddy) two wells, of 30ft. or 40ft. deep, have been dug in close proximity to the road, but no water reached. Small reserve tanks have been made where the spring issues from the rock above, and ladders have been erected against the face of the three cascades, so that the water above may be more easily reached. At Raraguddy the drinking water for the camp runs from springs into six tubs, placed on stones, and tanks have been built by the road side, from which the water runs by its own gravity into 54ft. of troughing erected for animals. At the foot of the Senafé Ghaut, arrangements for the water supply have been made, a tank has been dug, and four tubs placed for watering animals. At Senafé the supply is ample and has been well developed. Drinking water has been obtained from six Norton's tube wells. Water for camp purposes is provided in eleven tubs, fed by two additional Norton's tube wells. Water is supplied to the transport animals in 80ft. of troughing, led from a pond by a stone duct, and the surplus water is utilized in irrigating the soldiers' gardens. At Goongoona, Addigerat, and Antalo, arrangements have been perfected, but reports regarding them have not yet been received. Altogether, the important item of water supply appears to have been excellently well arranged, and its details satisfactorily carried out by Lieutenant Le Messurier and his staff, wherever water was to be found, although a scarcity is reported in some parts.

We finally come to the great trigonometrical survey of Abyssinia, which is being superintended by Lieutenant Carter, R.E. This officer reports that a base line had been measured at Koomaylee, and the position of a sufficient number of peaks has been fixed to allow of the topography of the country between Koomaylee and Senafé being taken up. Lieutenant Holdich, R.E., has worked up the Koomaylee route, and, with commanding points on either side, sketched in the country between Zoolla and Senafé. Lieutenant Carter has commenced triangulating, fixing points, and taking up the topography of the country between Senafé and Addigerat; the triangulation at and near Koomaylee has been connected with that at Senafé by a traversed line, executed by Lieutenant Dumler, R.E. By the foregoing work, it is hoped that a fair survey route of the army, showing the country on either side for a distance of from ten to fifteen miles, will be obtained, and, on the return of the army, more geographical information will be furnished.

Now, does all this read like the progress of an invading army in a hostile country? Does it not rather look like the report of a band of scientific explorers, who are doing their best to promote the ends of science, and to make themselves comfortable at the same time? Certainly, there ought to be a rich harvest of papers for the various learned societies, when the engineers, the telegraphers, the photographers, the well sinkers, the geographers, and the rest, shall have returned from their work. We are certainly returning good for evil, in that we are bringing a civilizing and humanizing influence to bear upon the territory of a savage who holds our countrymen in close captivity. And when we have accomplished our mission, and have released the prisoners—which we hope to do sooner or later—it may be that we shall hardly like to quit entirely a country upon which we shall have spent so much time and money. Although we have promised only to rescue the captives, and bring them home, we shall, doubtless, at the last moment, experience a lingering fondness for a country which may be found to present advantages for this, that, or the other purpose. This is, of course, beside our present question, but the circumstances are very suggestive. At present, we can hardly fancy the proceedings are the preliminaries of war: we are simply introducing the arts of peace and civilization into a savage country. But the stern war note has been sounded, and a struggle—perhaps a severe one—appears imminent. Then it is, when the fight has commenced, that men will feel

Digitized by Google

and appreciate the benefits resulting from those innumerable applications of science, and will acknowledge the high blessings they confer in depriving war of at least some of its horrors.

THE GOVERNMENT TELEGRAPH BILL.

WE are now enabled to place before our readers some details relative to the bill, which was brought in by the Chancellor of the Exchequer, and read a first time before the adjournment, to enable "Her Majesty's Postmaster-General to acquire, work, and maintain electric telegraphs." Owing to the forms of the House no discussion took place, and by reason of the lateness of the hour and the short time consequently permitted to him, Mr. Ward Hunt was unable to offer but few preliminary remarks. The preamble sets forth the reasons for the necessity of such a bill, viz.:—that the means of telegraphic communication within the United Kingdom are insufficient, and that many important districts are without any means of communication, and that there is nothing obligatory upon the parts of the existing companies to supply such districts, and that great advantage would accrue to the State, to merchants, and to the public generally if a "cheaper, more widely extended, and more expeditious system of telegraphy were established;" and consequently that it is considered expedient that "Her Majesty's Postmaster-General be empowered to work telegraphs in connection with the administration of the Post Office." The bill will make it lawful for the Postmaster-General to purchase out of moneys specially provided for the purpose, the "whole or such parts as he shall think fit, of the undertaking of any company," undertaking meaning the "whole or any part of the electric and other telegraphs, wires, posts, pipes, tubes, and other works, instruments, material, land, &c., and all other property whatsoever of any company;" but such purchase cannot be made without the consent of two-thirds of the votes of the shareholders of a company present in person or by proxy, at a general meeting of the company specially convened for the purpose; the sum to be paid for the undertaking to be mutually agreed upon between the Postmaster-General and the company, the distribution of which sum the Postmaster-General will not be bound to see to.

In taking over any undertaking the Government bind themselves to keep in full force all charters and grants, and to continue and complete all matters commenced by the company which would have been continued and completed by them. Provided that the Government have acquired by purchase the undertaking of any one company, the Postmaster-General shall purchase the rights of any other company if requested by them to do so, within twelve months of their possession of the first undertaking; this provision including railway companies who, possessing a telegraph open to the public, might request the Postmaster-General to purchase their right to transmit such messages or other beneficial interest they might have. Having mentioned the manner of purchasing the various telegraphs, the Act empowers the Postmaster-General to make regulations for determining the times at which offices may be open for the dispatch of messages and for fixing sums "to be from time to time paid for the transmission of messages, and for services rendered in connection therewith, and for the general conduct of telegraphic business;" but the bill itself provides that the charges for messages "throughout the United Kingdom shall uniformly, and without regard to distance, be at a rate not exceeding one shilling for the first twenty words of each message or part of twenty words, and not exceeding sixpence for each additional ten words or part of ten words." In such messages the names and addresses of senders and receivers are not to be counted; delivery by special foot messenger, if within one mile of the receiving office, or within the town postal delivery of that office, when it is a head post office, and the town postal delivery extends for more than a mile from it, not to be charged for, beyond such limits, if required; the charge for delivery to be sixpence per double mile, otherwise the message would be forwarded free of extra charge by the ordinary postal delivery next following the arrival of the message. The payments for all messages are to be made by means of stamps, for which purpose a proper supply of stamps and stamped paper would be prepared and kept for sale. A clause is also added, for appointing offices or pillar letter boxes as places of deposit for messages to be conveyed to the office of transmission, without extra charge, such messages to have stamps affixed to them of the proper value.

Such are the principal features of the bill now brought in; it is capable of many alterations, and no doubt it will receive many in committee, but of such it will at present be futile to speak. The great point is undoubtedly that the first step has been taken, that the Government are in earnest in proposing some plan to endeavour to improve our present system of telegraphy, and to bring it within the scope of all. The principal feature in the bill is that it is permissive, that if a company are perfectly satisfied with what they have got, they are not compelled to part with it, but we can hardly think that all the existing telegraph companies would in the face of this measure not respond to the overtures of the Government, and we cannot but feel certain, that if one company transfer their interest to the Government the others must speedily follow.

We have already gone into the advantages that must accrue to the public if the change really took place; but are there not advantages—indeed, great advantages—to the shareholders themselves in this transfer? We will take for instance the case of a merchant or one engaged in business, who is a shareholder in any one company. His position as a shareholder places him telegraphically in no superior situation to one of the public; if he wants to send a message, he must pay the same as any one else; his message has no prior claim; his only advantage is, if he is in a good company, an annual dividend of so much per cent.; but provided the transfer take place that advantage will remain the same, for it may be relied upon that the shareholders will look after their own interest in money matters. Everything that he gets now, he will get then, he cannot surely be worse off; with the transfer of staff and material he may expect to get his messages sent as expeditiously and as correctly. There are really no advantages that he enjoys now that the transfer will deprive him of; on the contrary, the advantages will be largely increased, extra facilities will be offered, places hitherto beyond his telegraphic reach will then be accessible, and he will in future be able to send two and sometimes more messages for what at the present time he has to pay for one. Instead of paying the high rates of one shilling for a short distance, two, three, or four shillings for greater distances, he will in future be able to send a message to any place in the United Kingdom for one shilling only. We can hardly imagine that any shareholder will oppose the pain; if he were to lose by it, well and good, but we can only see his gain. We are fully prepared to see opposition spring up amongst the administrators of the various companies; probably the ground of opposition being, as has already been advanced by them, that the Government will make a mess of it; this objection is absurd, for it amounts to the admission almost that they themselves are making a mess of it! For will not the Government work the various systems with the same *employés* that are complimented by them as being so efficient? In such a transfer there must of necessity be a decrease in the amount of administrative heads, and of course the directors would be the first to depart. Need we say more?

As regards the manner of payment, nothing is said, further than it will be out "of any moneys which may be from time to time appropriated by Act of Parliament and put at the Postmaster-General's disposal for that purpose." As to whether the purchase will be made by a transfer of the capital of the companies into a new Government Stock, we are profoundly ignorant, but we presume such will be the case. The bill has been anxiously looked forward to for some time, telegraphic enterprise and extension having been somewhat interfered with in consequence. But of all interested in it none have been more anxious than the *employés* themselves, an under-current of fear running amongst them that they will be superseded by penny postmen, and that many will have their services dispensed with. It of course stands to reason that if an amalgamation does take place under Government of four competing companies the services of a good many must necessarily be dispensed with, but we are satisfied that such a step will be accompanied by proper compensation. And we trust that whilst the shareholders and directors are looking after their individual interests, the interests of the clerks and *employés*, who have so well worked for their benefit, will have some one to see that in the change they are not neglected. To the public generally we are confident this bill will bring great advantages, the cheapness and greater expedition of messages, increase of offices and receiving stations, and consequently greater facility of intercommunication; it is a step in the right direction, and one which we hail with great pleasure as a boon and a benefit to the State and to the community generally. We shall carefully watch the progress of the bill and shall not fail to keep our readers constantly informed upon a matter that cannot be otherwise than of the greatest importance to them.

DR. LIVINGSTONE.

WHO among our readers, or who in the whole world, will not rejoice in the prospect of once more welcoming our veteran explorer, Dr. Livingstone, home? During the many alternations of hope and fear which have been experienced for long past, we have always felt, and have expressed ourselves, satisfied that positive evidence was required to convince us of Dr. Livingstone's death, and that if it had taken place we should have received proofs of it before now, if only to prove the old adage, that bad news travels fast. We do not wish to be considered as prophets after the fact, nor do we claim to have prophesied before the fact. Our view was always a hopeful one, and such as circumstances and Sir Roderick Murchison's experienced views justified. We are glad indeed, then, to learn that our hopes have not been in vain, but that a letter lately received by Sir Roderick from Dr. Kirk, at Zanzibar, gives us every reason to look for the great traveller's return at no very distant period. Dr. Kirk's letter is a long one, and will be waited for with impatient interest until the 27th inst., when it will be read before the Royal Geographical Society. In the meantime we are enabled to give our readers an abstract which has been made by Sir Roderick. The letter is dated February 4, and in it Dr. Kirk first announces the arrival of the Arab messenger, Bunduki, so long expected, who has brought despatches and letters from Dr. Livingstone himself. These letters, it is hoped, will arrive in time for the meeting at the Geographical Society before alluded to.

Digitized by Google

The information contained in Dr. Kirk's letter completely confirms the account of the route taken by Dr. Livingstone, round the southern end of Lake Nyassa, which was brought home by the Livingstone Search Expedition. It appears that our great traveller proceeded northwards at a long distance to the west of the lake, and in course of time arrived at Lobisa, formerly a thickly-inhabited town, but now almost deserted. In these elevated lands, covered with humid forests and destitute of game, the party suffered much from hunger; but, on approaching the southern extremity of Lake Tanganyika, they reached Mtuka, in the Wemba country, where there was abundance of cattle and food, and where they recovered their strength. It was here that Livingstone met with the trading caravans from Zanzibar, and delivered the letters to Bunduki, who has had them for twelve months in his possession. Reliable information has also been received at Zanzibar of the arrival of Livingstone at Ujiji, half-way along the Lake Tanganyika, where it is satisfactory to know provisions, stores, and letters sent from England and Zanzibar have long been waiting for him. Sir Roderick adds:—"The clear and definite proofs obtained by the boat expedition to Lake Nyassa, under the command of Mr. Young, quite satisfied most of my countrymen that I had judged rightly in adopting the belief that the whole story of the murder of Dr. Livingstone was a falsehood. But, since then, many have doubted the possibility of my dear friend ever coming alive out of the heart of Africa. With our present cheering information, every one may now, however, enjoy with me the prospect of once more welcoming David Livingstone on his return to an admiring country."

THE INSTITUTION OF NAVAL ARCHITECTS.

ANNUAL MEETING.

WE regret that we should again have reason to complain of the partial conduct of the authorities of this highly important institution, in affording to one of our congeners of the press priority (undue priority as we esteem it) in the use of the papers read at the annual meeting. We should have imagined that it would be thought advantageous to all the interests, whether public or private, concerned in the matters treated of, that all should have an early opportunity of seeing the papers. That, however, has not been done. Nevertheless, we shall give a pretty full *resumé* of the subjects treated of. The chair was taken at some of the meetings by those worthy "old salts" the Earl of Hardwicke and the Earl of Lauderdale, to whom it must impart many a pang, like "a shot in the locker," to see the iron "frights" that are so rapidly displacing their earlier loves. They will never be alone in sighing over this change, for though the stern requirements of expediency may banish the old three-decker to the regions of the ichthyosaurus and the dodo, yet "the thing of beauty will be a joy for ever," and if she walks the waters no more like a thing of life, she will live in our fancy and unavailing regrets.

Having given the report of the council and the chairman's address in our last, we now turn to the papers read, and shall first notice that by Mr. Henry Sharp, of the Bolton-le-Moors Steel and Iron Works, on the treatment of steel plates. The rapid displacement of iron by steel in this manufacture, during the last few years, leads to the inquiry—Where will it end? Wood has nearly disappeared before iron, and the latter seems destined ere long to disappear before its younger brother in shipbuilding, boiler making, and most other structures of ferruginous material. Even the rails of our iron roads have, in some cases, been superseded by steel, while the axles and tires of the wheels which glide over them, and the piston rods which drive them, &c., have been changed to the same material. Even the boilers of locomotives seem to be putting in a claim to the same consideration as those of stationary engines, which have submitted to this material change, and seemingly, on the whole, with good results. The increased strength without additional weight, or the diminution of weight with unaltered strength, recommends this substitution. Experience, however, shows that great care must be used, so as not to obtain an inferior and more brittle article, by beating down the price. It is enough to save a large percentage in one way, and not seek, by grasping at too much, to lose the advantages which are really within our reach. A few failures, due to inferior articles at low prices, have tended to cast discredit on steel plates, &c., which, *per se*, they do not deserve. The same care in selection of material, and, if possible, more in manipulation, should be used than in the case of iron.

Mr. Sharp has given us here a very interesting paper on his own experiments on the tensile strength of steel, which, as he very properly states, depends in large measure on its hardness. This very hardness becomes, under bad or injudicious manipulation, its chief weakness. For instance, in the simple method of perforating the plates, it becomes of importance whether this be done by drilling or punching. The latter has been proved to deteriorate the plates to the extent of 33 per cent., or just one-third of their whole strength. Common sense *á priori* might almost predict such a result from the heavy jar of the punch on a harder material, yet, as punching is more convenient than drilling, for more reasons than one, we are glad to learn that careful annealing will, after punching, restore the "jarred" plate to all its original goodness. Such experiments go far to remove the hasty objections made to the use of steel for the wider purposes to which it is being applied.

This paper concludes with a very interesting and instructive paragraph on the value of conical, as opposed to cylindrical perforations. Tapering holes were made with much less force than the other; they injure the texture of the plate in their immediate neighbourhood much less, and do away with the necessity of countersinking. This paper fully realizes the basis of the Baconian philosophy "experiment," but we believe that each and every result which Mr. Sharp here brings before us, could be fully borne out by abstract and *á priori* induction.

On the subject of steel a second paper was read by Mr. Rochussen, in which he pointed out the mistake made by Lloyd's and the Admiralty, when iron first began to be used for shipbuilding, in fixing a standard for one element of strength only—namely, tensile strength along the so-called fibre. This led to ships being built for insurance rather than for safety. Builders, whose interest was in the safety of their ships, made use of better iron, which would not only satisfy the regulation test, but had other good qualities which should have been recognized from the first as indispensable. These were the men who introduced steel at a later period, and are still advancing in the road of improvement. In speaking of hard steels, Mr. Rochussen pointed out that annealing was looked upon as a sovereign remedy against all accidents which might arise from the steel's having been overheated. This process of annealing, he said, would seriously affect the price of steel, as the builder would be compelled to materially increase his plant in erecting furnaces for the annealing of large plates. All this, he stated, might be avoided. In a ship of 2,000 tons there is no portion which cannot be worked cold; heat is not necessary, is even dangerous, while the fact of working cold is a conclusive proof of the excellence of the material. There was another point in this paper to which we must allude, and that is what Mr. Rochussen calls the "stored strength" of the steel. When a sufficient strain is put upon a steel rod, its elasticity is impaired, and ultimately destroyed. Its sectional area, meanwhile, is decreased. The strain on the square inch of this diminished area which is required to break the steel when in this weakened state is the stored strength. It appears that this quality is greatest in the mild steel of low tensile strength, and lowest in hard steel and iron of very high tensile strength, clearly showing that the latter kinds of metal are dangerous material to employ in structures liable to sudden strains of great magnitude.

One of the most interesting, and perhaps it is not too much to say, one of the most important, of the papers read was that of Captain Selwyn on "Liquid Fuel." He showed that by the use of the liquid instead of coal a ship could, with the same weight of fuel, be supplied for a voyage of more than three weeks under steam, instead of for one week, and that the change would be attended with two great advantages—the owner would pay less for his fuel in the first place, and, in addition, could have more room available for freight. The fluid of which Captain Selwyn spoke particularly was that generally known by the name of creosote, the price of which is at present ¾d. per gallon, or 13s. 9d. per ton. One of the great advantages of it is its heavy specific gravity, being somewhat greater than that of sea water, so that in case of fire, arising either from accident or from an enemy's shot, the fuel might be run into the hold, where it would sink in the bilge water, or, in case of still greater danger, into the sea, where it would immediately disappear. Creosote is not inflammable at less than 240deg. Fahrenheit, so that there is no danger of explosion, nor is it liable to spontaneous combustion, as coal is. The liquid fuel might be stowed in tanks, situate at any part of the ship, and thus a great saving of space obtained, which cannot be made available for the stowage of coal. From these tanks the fuel might be pumped into the cisterns from which it would run, under the action of gravity or of artificial pressure, into the supply pipe which feeds the furnace. When once the furnace is at work, the stoker's labour is confined to merely watching the furnaces, of which he may attend almost any number, merely turning the taps which supply the creosote. Two pipes are fitted to the furnace, one of which admits steam and the other the oil. The steam pipe enters the furnace just below the oil pipe, and the function of the steam seems to be merely to scatter the oil in a kind of spray so as to facilitate combustion. Air may also be admitted under pressure through a third pipe, so that the amount of oxygen supplied to the fuel may be regulated, and complete combustion thus arrived at. It is interesting to hear that a Cornish 35-horse power boiler, with Galloway tubes, has been at work for some months at Hackney Wick, doing more work with a supply of liquid fuel (which in this case is coarse naphthalin) of 230 gallons a day, than it did before with 3 tons of coal. The difference of the expense is 5s. compared with 72s. The water evaporation obtained from a fortnight's observation was 23lb. for every pound of fuel. As 7lb. of water evaporated for 1lb. of coal represents the maximum work which can be reached at present by the best boilers, we may allow that this is a direction in which we may look for great advances in economy. We are glad to hear that an experiment is being made with this system, though on a small scale, by the Admiralty. A steam launch is being fitted with the oil-burning apparatus, but we are warned not to expect too much from the results of this trial. A second Cornish boiler, without Galloway tubes, the furnace of which was arranged in a somewhat novel

Digitized by Google

manner, has actually with 109lb. of oil done the same work that it had previously done with 672lb of coal; and the extraordinary amount of 46lb. of water evaporated for 1lb. of oil is stated to have been reached, which is double the amount generally given as the full equivalent for 1lb. of this compound. If this turns out on more exact investigation to be correct, the explanation must be looked for in the combustion of the gases admitted under the form of steam.

A paper to which we cannot afford an equal meed of praise, was read by Mr. Longridge on a monitor for harbour defence, and submarine artillery. It was proposed that the monitor should have its plates inclined at small angles to any fire which it was likely to meet with, which we cannot look upon as a new idea, seeing that an inclined target was built some time ago for experiment at Shoeburyness. The striking feature of the paper was the advocacy of an underwater gun, or, we should say, broadsides of such guns. The monitor, impervious above, is to run close up to any enemy audacious enough to enter the harbour, and give it at close quarters the full benefit of its submerged guns. It remains for Mr. Longridge to prove, first, that the guns will not burst in firing; secondly, that the firing of the guns will not be very destructive to the monitor's own sides; and, thirdly, that the shell will be likely to do more harm to his enemy than to himself. We cannot but look at the scheme of submarine artillery as wild in the extreme.

We shall discuss the remaining papers next week.

AERIAL LOCOMOTION.

LORD MACAULAY made a journey through the lapse of years and pictured future ages with a civilized New Zealander meditating on the ruins of London Bridge. The editor of an American paper a short time ago imagined the present century to have passed away, and pourtrayed the state of society in 1960-1970. A lady is entertaining a few friends just before dinner, and she tells them they will not have long to wait—her husband has only gone to pay a visit in the neighbourhood of "Boothia," and she expects him in New York on his return from the North Pole every minute!!! Wonders will never cease, and considering the earnest way in which the Aeronautical Society is going to work, we should not be at all surprised to learn that travelling in the air would soon become as easy and as regular as travelling by land or by water. Even in prehistoric times we find that men were evidently addicted to emulating birds and bats; but up to this year of grace 1868, hardly anything has been done towards rendering journeys through the aerial regions either safe or easy. Now it appears to us that the cause of failure hitherto has been the too close imitation of the means employed by birds to travel through the air. Sailing vessels or steam packets are not propelled in the same manner as fishes through the water, or even on the same principle as boats are rowed over the waves, nor do our locomotives imitate the walk of men, although it is true there is to be a steam man employed as a motive power to put trains in circulation. But he is only talked of, and has not yet given any signs of life, and besides we must remember this is an American story.

According to our ideas, after making the framework of an aerial machine hollow, so as to diminish as much as possible its specific gravity, some new motive power should be applied. Let us endeavour to find out what this should be; to do this we will examine existing methods of locomotion. Take the case of a horse and cart; the simpler the illustration the better. Here, the horse exerting the leverage of his muscles against the earth, first moves himself and then draws the cart, to which he is attached, after him, and by thus drawing he makes the wheels rotate, by which means the cart is made continually to shift its place. Now, it is exactly the reverse in the case of the locomotive, there the *που στω* (*pou sto* or fulcrum which Archimedes said if he could obtain anywhere out of the world he would be able to remove it from its solid basis and destroy its equilibrium) is inside the machine, and by forcing the tyre of the wheel to turn, effects the transplacement of the locomotive, but in a directly opposite manner to that in which the cart is moved from its position. In the one instance the horse standing on, and pushing against, the ground, moves forward and draws the cart after him, and lastly, makes the wheels turn upon their axes. In the other, the steam in the cylinder exerting its power against the ends of it, forces the piston to alternate back and forward. The pushing or pulling motion being thus converted into a rotating motion by acting on the leverage of the crank axle, obliges the wheel to change its position on the road, and by continually changing its position, to move, not itself alone as the object accomplished at the end, ultimately, but actually to move the carriage in which the motive power itself is fixed. Thus, though the ends of the cylinder are stationary as regards the piston, yet by the revolutions of the wheels they are all moved on together, cylinder, piston, wheels, and all.

Now it appears to us that for aerial navigation, instead of using screws and paddles as in steamers, or cylinders and pistons as in locomotives, it might be well to condense the air very much by means of chemical agency, and then to force it through hoppers in concentrated quantities against the circumambient atmosphere, preventing as much as possible its diffusion. We should thus make the aerial traction-engine act in the inverse way of a bullet, which is impelled by being forced, a short portion of its course, by a rush of air, wonderfully condensed by the ignition of powder behind it. We would propose that the condensed air should be manufactured in the aerial locomotive and be judiciously expelled from it with great force and in a constant stream flowing towards a point or line. It would even then only too soon dilate, and would exert, as it were, a kind of continuous impact against the surrounding aerial space, which by its elasticity would resist it and thus enable the aerial traction-engine to wend its way in any required direction, as well as to ascend or descend either vertically or obliquely. This we believe to be the true theory of the aerial traction-engine; we leave its practical development to those who are now directing their attention to the solution of the subject. When once the idea is mastered we should probably find ourselves traversing the winds with the same facility and with greater rapidity than we now do the waves.

LANDSCAPE PHOTOGRAPHY.

FOR some months past there has been an outcry in the photographic periodicals, demanding small photographic cameras for tourists, because now that enlarging is getting so common, a large picture on collodion may be taken from a very small negative, if needed. Moreover, it is a boon to amateurs, as well as to professionals, to be able to carry landscape apparatus and plates in the pocket, and the legs in the hand in the shape of a walking-stick. Although negatives so taken must be small ones, it is possible to make up in beauty what the positives want in size, by printing them as transparencies upon opal glass.

The demand for such small apparatus did not quickly call forth a supply, but Messrs. Negretti and Zambra have just began constructing pocket cameras, which, at present, sell as fast as they are made, and we hear of two or three other firms about to follow the example. The camera by Messrs. Negretti and Co. is made of mahogany upon Kinnear's principle, and takes negative plates 3¼in. square. This size has been chosen because the measurement is just right for magic lantern pictures, to be used with the ordinary 3¼-in. condensers, the most useful size for dissolving views, and the glass paintings ordinarily on sale in the shops. Hence, without enlarging apparatus, pictures taken in the little camera may be printed direct upon dry collodion plates, for the magic lantern. The camera, when shut up for the pocket, occupies a space about 4¼in. square by 2¼in. thick. The sliding backs carrying the plates, must, of course, be carried separately. These are rather thicker than desirable in outside measurement, and perfection in small apparatus of this kind will not be reached until some manufacturer devises double dark backs not much thicker than the two glass plates inclosed inside. Probably thin metal would answer better than wood for this part of the camera. The camera itself has no spare space inside for the lenses.

The purchase of a lens or lenses for small pictures of this kind demands consideration on the part of the investor. Most of the small lenses in the market take in a larger angle of view than the human eye—therefore imprint a larger range of subject upon the photographic plate. At first sight, this may seem to be an advantage, as the operator gets more in his picture; but, on the other hand, objects in the foreground appear of unduly large size when compared with those in the background, and the view, in short, seems less true to nature than it is in reality. For special subjects it is convenient to have wide-angle lenses, but for general use, in a camera like this, we recommend a meniscus landscape lens, with front stops of different sizes, and the lens should not include a larger angle of view than 50deg. or 60deg., so as to correspond with the angle included by the eye as nearly as possible. Single landscape lenses are less bulky and expensive than double combinations, and they give capital definition, but are not quite so well suited for portraits and architectural subjects as other lenses, when these objects have to be taken the full size of the plate.

As a matter of fact, "satchel" camera is a much better name than "pocket" camera for apparatus like this, when the photographer wishes to take out a dozen plates with him, to retnrn home with a dozen pictures. Anybody going out for the day in the midst of picturesque scenery, will find three or four plates too few to meet his requirements, from eight to twelve being a convenient number. This is the reason why, in portable cameras, it is necessary to devise some method of economizing space in the dark slides to a greater extent than is the case in the little instrument now under notice. A lens is an awkward object to carry in the pocket, so also is the top of the camera stand, and in practice it will probably be found that the best form of travelling appa ratus for 3¼-inch preserved plates is a rect angular box, carrying the camera inside with the lens in position, so that directly a door at the end of the box is opened, the lens is exposed to the view to be taken. Other doors in the box will give access to the dark slides, and permit the focussing screen to be seen and adjusted. By means of a simple contrivance of this kind, the tourist would not be losing time in screwing the parts of the apparatus together before taking each view, and it is not very creditable to manufacturers that most of the box cameras in the market entail such waste of time upon those who use them.

It is an excessively difficult matter to make a perfectly rigid walking-stick tripod stand for a camera; in fact, most of these are failures when exposed to the test of taking a picture in a high wind. Rigidity and se-

Digitized by Google

curity from vibration can probably be obtained only by means of legs with the ordinary forked tops to bite the upper portion of the stand, and such legs thick enough to work efficiently will not look like a walking-stick when closed. Here, again, the tourist had better sacrifice appearances to efficiency, and furnish himself with a tolerably firm stand without folding joints. The triangular piece at the top should be made of wood, and rather small, so that when the legs are screwed to it they will not diverge much at the upper part, and will, therefore, be easy to carry "in position" when several views have to be taken at no great distance from each other. When the views to be photographed are a considerable distance apart, it will be more convenient to detach the legs from the wooden apex, and carry them braced together so as to form a rather thick staff. The danger of the present call for very small portable cameras is, that efficiency will be sacrificed to portability, and this, as all practical men know, is a mistake. The small cameras for tourists now coming into the market will make many practise photography who never attempted to do so before, for everybody likes to be able to secure pictures of familiar scenes, when it can be done without much trouble.

STEEL FROM THE CLEVELAND IRON.

A SOLUTION of the important question of the conversion of Cleveland iron into steel has long been sought, but in vain, great and manifold difficulties having hitherto stood in the way of the accomplishment of that object, owing to the overpowering presence of phosphates in the iron. The matter has, however, attracted great attention of late, owing to the circumstance that the question has advanced beyond the realms of theory and speculation, and has almost become a practical fact. To show the energy which is being brought to bear upon the subject, we may observe that experiments are now being carried on with no fewer than five different processes for making steel from the Cleveland iron. Several specimens of steel thus made have been submitted for trial and a satisfactory verdict has been pronounced upon them. There is, however, but one out of these several processes of which the details have been made public, and this is that invented by Mr. James Hargreaves. The particulars of this gentleman's invention will be found fully given in our issue for the 10th of January last. We need not, therefore, repeat them here, but at once turn to the more practical points of the question, which were considered in a paper lately read by Mr. Hargreaves before the Cleveland Society of Engineers, and were further elicited in the discussion which took place thereon. Mr. Hargreaves fully defined his method of procedure, and from the trials he has made he appears to secure the maximum results with the minimum cost, and the steel produced seems to be of the best quality. In the discussson Mr. Whitwell stated that Mr. Hargreaves had brought a chisel made from Cleveland iron to his works, the edge of which on hammering very hard at a piece of chilled iron was only dimmed, whilst the edge of a tool, made of the best Sheffield steel, when put to the same test, was turned completely up. This must be equally as satisfactory to the Cleveland iron masters as to Mr. Hargreaves, and we congratulate both parties upon the result. The increasing demand for steel in construction purposes renders it clear that if Cleveland iron cannot be converted into steel it must decrease in value, in proportion as other ores more free from phosphates advance in price.

The discussion to which we have referred turned upon another point of equal interest and importance—the utilization of the phosphorus extracted from the iron. The direction in which it might be utilized would, of course, be the manufacture of phosphorus, phosphoric acid, and other chemicals. As a proof of the importance of this matter it is stated that the phosphorus extracted from Cleveland iron would, even in its cheapest form as manure, be worth at least £56 a ton; as one ton of phosphorus is equal to 2 tons 5cwt. of phosphoric acid, or 4 tons 10cwt. of the highest qualities of Patagonian, or 7 tons of Peruvian guano. According to Mr. Hargreaves' showing iron which is now worth 47s. per ton, when containing one per cent. of phosphorus, would, if freed from this element, be worth at least as much as hematite iron, or say 54s. per ton. On this showing, the account stands thus:—

100 tons of phosphoric iron at 47s., £235.
After being freed from phosphorus—

	£	s.	d.
99 tons of iron at 54s.	267	6	0
One ton of phosphorus or its equivalent (say in the shape of phosphate of lime)	56	0	0
	£323	6	0

making a difference in favour of the purified iron of £88 6s. on 100 tons, or 17s. 7½d. per ton of iron operated on. We have thus two important questions to be solved—the first, the conversion of Cleveland iron into marketable steel, and the second—which grows out of the first—the utilization of the phosphorus. The first is now being practically worked out, the second we commend to our chemists, to whom it offers an interesting and, probably, a profitable object for study and experiments. Looking at the progress which has been made by Mr. Hargreaves, in the solution of the steel question, we cannot be otherwise than hopeful that, in the course of time, Cleveland steel will take its place amongst the choice brands in the market.

NOTES ON RECENT SCIENTIFIC DISCOVERIES AND THEIR PRACTICAL APPLICATIONS.

BOTTLE TO CONTAIN LIQUEFIED GAS—A STRONG AND LASTING CEMENT—BRASS PICKLE—CAN FOR APPLYING LUBRICATING OIL—EXPLOSIONS OF RED FIRE.

THE use of protoxide of nitrogen, or laughing gas, as an anæsthetic agent, is no novelty, and would not require notice here, but for a suggestion recently made in the "British Medical Journal" which offers a problem to mechanics. It would be very inconvenient for surgeons to be driving about with large bags of gas for administration to their patients. There are inconveniences also in the preparation of the gas on a small scale which disappear when the manufacture is carried on in a moderately large way. Now, laughing gas can, by great pressure or intense cold, be condensed into a liquid, and the suggestion of the journal we mention is that liquid protoxide of nitrogen shall be sold, from which at any moment, by merely turning a tap, a bag of gas can be obtained for inhalation. To carry out this idea, bottles are required which will stand a pressure of at least 800lb. The pressure at which the gas liquefies is about 30 atmospheres at the freezing point, so perhaps for a bottle to be perfectly safe at our ordinary temperature, it should be proved to 1,000lb. There can be no difficulty, we should think, in producing such a bottle of cast steel, so light that a surgeon might take it with him on his rounds, and if there are all the advantages claimed for protoxide of nitrogen as an anæsthetic, there will probably be a considerable demand for such bottles. As regards the manufacture of the gas, and its liquefaction, these are very simple matters: the desideratum of to-day is a safe and portable bottle to hold the liquid, and we have little doubt that this will soon be furnished.

A very strong and durable metallic cement, we read in a German Mechanics' Journal, is formed when a mixture of equal parts of oxide of zinc, sulphate of lead, peroxide of manganese, and oxide of iron is made into a paste of proper consistence with boiled linseed oil.

Dr. Hiller writes that the brownish red colour often obtained when brass work is pickled in the usual mixture of acids, may be avoided by making use of a mixture of equal parts of commercial nitric and sulphuric acids. Articles dipped in this mixture and then well rinsed in cold water have, he tells us, a very beautiful dead yellow colour.

A new can for applying lubricating oil is described in "Cosmos." It is a cylindrical vessel of a size that can be grasped by the hand and is much the same in shape as that in common use. The top, however, is flexible, and there is a spiral spring in the interior. When oil is required the workman presses with his thumb on the top and forces out just the amount necessary. On removing the pressure the spring restores the can to its shape, and the oil in the long spout is forced back by the influx of air. Thus there is no waste of oil by dripping.

The frequent recurrence of such accidents as that at Nottingham—not often, however, so fatal in their consequences—justify us in giving a general caution to any readers who may be disposed to amuse themselves with making coloured fires The ingredients for red fire should be powdered separately, and they should be mixed in a sieve and never in a mortar by means of a pestle. With this precaution the mixing of the colour is perfectly safe; but the liability to spontaneous combustion some time after it has been mixed is as great as ever. The spontaneous combustion, however, is not attended with explosion.

ROYAL POLYTECHNIC INSTITUTION.

ACCORDING to custom the Easter programme of the Polytechnic Institution has been entirely changed and features of novelty everywhere present themselves. In the first place, the large theatre has been redecorated throughout, and separate entrances have been provided for the reserved seats, a boon which will be duly appreciated by visitors who desire to avoid the former scramble for seats. Then the entertainment has been remodelled in all its varied details, and presents from first to last a series of the most interesting illustrations of science in a popular but truthful form. Those who have followed Professor Faraday's brilliant discoveries in electricity and the chemistry of colours will now learn the results of that philosopher's optical experiments. They will also find much to interest them in the thaumatrope, the kalotrope, the phenakistoscope, Mr. Rose's photodrome, and the zoetrope. Professor Pepper, in exhibiting the zoetrope, skilfully throws the figures seen through one aperture only upon the disc, which produces some grotesque animated figures. The photodrome shows how objects may be put in rapid motion in the dark, and yet appear perfectly at rest when momentarily seen by a flash of light. Spirit rapping and table turning come in for their share of exposure at the hands of Professor Pepper, who, by simple mechanical means, proves himself quite at home in his exhibition of spiritual manifestations, directing the flight of persons and things through space. The shadow Blondin on the high rope amuses, whilst the lecture by Mr. King, on the Chassepot and other rifles, instructs. The optical dioramic illustrations are all new, and include a remarkable moving skeleton, which has been arranged by Professor Pepper and Mr. Tobin, his active coadjutor, who, we are glad to observe, has lately been appointed secretary to the Institution. We cannot but compliment the management on the success of their Easter entertainment, which, we need hardly add, is always thronged by those who seek to combine pleasure with the acquirement of a knowledge of scientific things.

SOCIETY OF ENGINEERS.

(Concluded from page 275).

THE foundation at starting was very good, being a sandy clay, dry and firm. This continued, however, only for a length of about 50 yards, at the end of which a small brook was crossed and the treacherous morass entered upon; although at a dry season of the year, the ground was wet and sloppy, and in some places so soft as to be dangerous to walk on. A few days previous the author had surface drains cut as deep as the level of the brook would admit, and connected with it at a point as far down stream as was practicable. The surface water was thus drained off to a depth of 1ft. or 18in., and the ground through which the

Digitized by Google

excavation was to run rendered fitter for moving about materials; it was never, however, hard enough to admit of cartage, which necessitated planking to be laid for wheelbarrows to convey all the required materials. The depth of the sewer, from the commencement of the morass to the Brighton-road, averaged under 5ft., so that the crown of the arch was above the surface of the field. The subsoil may be described as soft peat, black, mixed occasionally with clay and sand, not fibrous like the Irish bogs, and very wet. Of course an artificial foundation was necessary on such ground, and from the three which were described in the specifications, and of which drawings were furnished, the author decided one, which was formed of hurdles interlaced with brushwood laid on three longitudinal sleepers not less than 16ft. long, and covered with concrete which reached to within 18in. of the springing of the arch. The concrete was composed of four parts of broken stone, two of sand, and one of Portland cement, or about one cask of cement to a yard of gravel and sand. In getting in this foundation, the method adopted was to excavate a 16ft. length and sink a sump hole, the sleepers were then inserted so as to break joint, the hurdles, which were 6ft. × 3ft., laid over them, and a layer of concrete 6in. thick tipped in from barrows. The hand pumps were kept at work to keep the water down until this layer had sufficiently set. A wooden template of the exact form of the outside of the sewer, and 10ft. or 12ft. long, was then suspended from cross-timbers so that its lower extremity just touched the layer of concrete, and the spaces between this template and the sides of the excavation were filled in with concrete to the required height; when this had set sufficiently the template was moved on, and another length completed in the same way. Before commencing to put in the invert in the first instance, the foundation was tested to ascertain if any subsidence would occur; for this purpose the pumps were stopped, the templates allowed to rest on the concrete bottom, and then loaded with bricks equal to 2½ times the weight of the sewer for that length, levels were taken from a bench mark on an adjacent bridge, and after a fortnight taken again: no perceptible subsidence had taken place, and the brickwork was then proceeded with. In excavating, it was found necessary to remove the material some distance from the side of the trench as it was taken out, for though the sides were close timbered the additional weight forced up the bottom. This moving away of material, and moving it back when the sewer was completed, caused this part of the work to proceed but slowly; some difficulty was also experienced in drawing the runners after the brickwork was got in, owing to the tenacious nature of the soil. The author should mention that the foundation was slightly modified:—1st. The concrete was brought up perpendicular at the sides flush with the sides of the excavation; 2nd. Square sleepers of foreign fir, 5½ in. × 5½ in., were substituted for fir poles 6in. diameter; and, 3rd, one foot of concrete was laid over the hurdles instead of 6in. The total length of the 2ft. 8in. × 3ft. 9in. sewer was 223yds. The details of the cost will be given at the close of this paper in connexion with that of the other sewers.

At the manhole, the main sewer turns at right angles along the Brighton-road, diminishing in size to 3ft. 6in. × 2ft. 6in., and at the same point is joined by a 15in. pipe sewer diminishing to 12in., which will take drainage from the high ground in the extreme south of the district. The ground traversed by the 3ft. 6in. × 2ft. 6in. sewer from the manhole to where it turned off the road was, with one exception, the worst the author had to deal with. The peat continued at the surface for a distance of about 350ft. along the road, it averaged here about 6ft. deep, and gradually passed into a sandy clay abounding in green grains, and very watery. Lower down, the clay disappeared, and a quicksand was met with for the first hundred feet; and while it was not necessary to go lower than the peat, the hurdle foundation was continued as before; but as the excavation proceeded along the rising ground the sand was encountered, and here it was found necessary to adopt a foundation, consisting of 4in. planks spiked to the sleepers and covered with concrete: the same modifications were observed in this instance, the concrete being carried up perpendicularly at the side, and a layer one foot thick tipped in over the planking. Proceeding still further, the strata sunk through were peaty clay and peat to a depth of 6ft.; under this a hard stiff blue clay quite impermeable to water, and upon excavating this, it was thought all difficulties were over, as it seemed probable that the clay continued to a considerable depth. Such hopes proved delusive, for when about 18in. of the clay had been excavated water showed itself oozing from the bottom and sides, and when another 6in. had been removed the excavators found themselves in a quicksand. The water being under pressure here, owing to the impermeable stratum overlying the permeable, was more abundant and more difficult to deal with than before, and not having been so well prepared for it caused some mischief.

The timbering had been put in, in separate frames 4ft. deep, the walings were placed across the centre of the runners, and the struts 6ft. apart. The peat on the surface necessitated the runners being placed close; had the clay continued only 2ft. or 3ft. deeper this would have been amply sufficient, but (for misfortune never comes alone) it happened that on the very evening this artesian spring of sand and water was tapped there came a thunderstorm and heavy fall of rain, which soon found its way from the steep slopes on each side of the valley to the works, down behind the timbers, joining the springs below. Pumps were kept constantly at work in the trench, but in spite of all, the lower frame of timber gave way and the sand burst in, the surface of the road at each side of the excavation sunk at the same time about 4ft., owing to the sand having been drawn from underneath, adding to the strain on the top frame and breaking many of the struts. The men, however, though drenched with rain, stuck bravely to their posts all night, fresh runners 14ft. long, extending the full depth of the excavation were obtained and driven outside the walings, and by dint of the most creditable and untiring exertions on the part of the foreman, the trench was kept open, and the water kept under until the morning. Of course, after this the system of timbering with separate frames was abandoned, runners the full depth of the excavations were used, and the thickness of the timbers increased to 4in.; these, of course, projected a great height above ground until the excavation was carried down to a considerable depth, for which reason, as well as because the material could not be taken out by shoveling it on to the stages, owing to the quantity of water it contained, shear legs were erected of sufficient length to clear the tops of the runners, a horse gear attached and the sand drawn up in buckets. As may be supposed, some difficulty was experienced in getting the brickwork dry, and even when one length had been completed, and the pumps removed preparatory to getting in the planked foundation for the next, the water as it rose would force its way through the concrete, and in some cases through the joints of the brickwork while the cement was green; to reduce the pressure behind the brickwork drain-pipes were at first inserted a few courses from the bottom of the sewer, which reached across the concrete to the side timbers, and admitted a considerable portion of the water into the sewer, where it flowed to the outfall. These, it was found, did not admit the sand, although the contrary might have been anticipated, and it may be generally remarked that, although where there is a free surface exposed, water will carry a large quantity of sand, yet a moderate amount of friction will retain the latter. Thus it was always noticed that although so much sand was drawn through the pumps as to require them to be frequently stopped for repairs, before the planking could be got in, yet directly that was accomplished the water was thrown out of the pump holes comparatively clear, and when the length of brickwork had been got in perfectly so, and the quantity of water remaining the same, to diminish the chance of the entrance of sand through the safety vents (as they may be termed), the author adopted the following expedient:—

As soon as a length of planking had been got in, and before the concrete was laid, vertical pipes were placed at intervals at each side of the trench, these were generally 6in. earthenware socket-pipes, which, from the presence of fire cracks, or from other defect, had been rejected. They were placed socket downwards, resting on the planking, and were filled with gravel; the concrete was then tipped in and the brick sewer carried up as usual until it reached as high as the tops of the pipes. Two-inch agricultural drain-pipes were laid connecting these vertical pipes with the sewer (the edge of the pipe being chipped to receive them); they were laid with a slight fall pointing in the direction of the flow: the remainder of the sewer was then completed, and the tops of the vertical pipes covered in with concrete when the pumps were moved on, and the water allowed to rise through the vertical-pipes and thence into the sewer. After this method was adopted no case of a joint being injured by the pressure of the water underneath occurred. The whole length of the main sewer where these inlets were inserted has been examined at different times by the author, particularly after heavy rains, and found to be entirely free from any trace of sand. It may be remarked here, that the admission of subsoil water into a sewer is in all cases recommended by Mr. Rawlinson, though it had been objected to by some engineers on the obvious ground of the dilution of the sewage: This objection only partially applies; first, the water admitted by this means is inconsiderable compared with sewage, which ordinarily flows even in dry weather; second, it must be borne in mind that spring water is not distilled water, that it holds in solution a variety of fertilizing salts; and thirdly, the evil of dilution is in many instances overrated, for if the sewage is so applied to the land, so to leave there all its fertilizing matter to be utilized, it seems to the author to be of no great consequence (within certain fixed limits), whether that fertilizing matter is conveyed there by a greater or lesser amount of water, the principal object being that the water as it leaves the land should contain a minimum of organic matter.

The author wishes it to be clearly understood that he would on no account recommend means to be provided in a main sewer for the admission of subsoil water properly so called, that is, water percolating from the surface, and intermittent in its flow; for when such means of ingress were not employed in letting in water, they would be in letting out sewage, and sewage gases. But it is otherwise with deep-seated and constant springs, especially if they happen to be artesian springs, derived from a water-bearing stratum underneath an impervious one, and acting under pressure; in such cases, it is better to admit it, or part of it, than go to increased trouble and expense in excluding it, providing only that nothing but water is admitted. Excepting these inlets, the sewer was practically speaking water-tight, the brickwork being laid in cement, and both rings of the arch rendered on the top with a coating of cement. That it was so was proved by sending a man through from one manhole to another after some heavy rains had fallen; the back of his coat was somewhat dusty from contact with the arch, but was perfectly dry.

The remainder of the 3ft. 6in. × 2ft. 6in. outfall sewer, after getting through the quicksand, presented no peculiar difficulty; upon leaving the road the peat was again encountered, and the same foundation used as that described for the larger outfall sewer near the temporary outfall. One thing, however, should not be omitted to be noticed in connection with these springs. Several new houses were in the course of erection on the side of the hill, west of the Brighton-road, and to supply these with water, deep wells had been sunk through the dry upper sand into the quicksand below; some of these wells were upwards of 60ft. deep, and the nearest about 200yds. from the sewer. So rapid is the flow of water in the stratum that all the wells were dried within two or three days after the trench was opened to its full depth; the bottom of these wells were exactly 10ft. above the invert of the sewer, and by levelling from them the author determined the approximate inclination of the water-bearing stratum, which was about one in twenty.

The sewers are laid out in what may be called the modern rectilineal system, *i.e.*, in straight lines from point to point, having a manhole or lamphole at every change of direction, and, with very few exceptions, at every change of gradient. The advantages derived from this method of construction need not be referred to here; but in addition to recognized utility, the author would direct attention to the facilities it affords for determining questions relating to the flow of sewage, for testing or correcting the accuracy of general formulæ and tables; for, possessing an uniform rate of inclination, a constant sectional area, and a given length in a straight line between every two manholes, we have so many independent data for basing general conclusions on. The sewer pipes were 15in., 12in., 10in., and 9in. in diameter. They were specified to be of fireclay or stoneware, to be moulded under pressure, and the socket of every pipe to be pressed on or formed with the body of the pipe, and to be truly concentric with the pipe. Pipes were to be rejected which were, first, not well nor uniformly glazed; second, not properly burnt; third, which contained injurious fire cracks; fourth, not true in section; fifth, not perfectly straight in the direction of their length. The thickness of the material of the pipes of the several sizes were to be as follows:—

Digitized by Google

Stoneware. Diameter.	Thickness.	Fireclay. Diameter.	Thickness.
4in. ...	½in.	4in. ...	½ in.
6 „ ...	⅝ „	6 „ ...	¾ „
9 „ ...	¾ „	9 „ ...	⅘ „
10 „ ...	⅞ „	10 „ ...	1 „
12 „ ...	1 „	12 „ ...	1 1/10 „
15 „ ...	1⅛ „	15 „ ...	1¼ „
18 „ ...	1¼ „	18 „ ...	1½ „

The pipes supplied were in all cases stoneware, and of the thickness specified for that class of pipe. They were whole socketed. In laying the pipes great care was taken that each pipe was supported at every point by cutting cavities to bed each socket in, and in cases where planked foundations were required under the pipe sewers, the planks were covered with sufficient material, well trodden down and consolidated, to allow of this most important point being attended to. The jointing was executed with well-tempered clay, which was forced into the joints by means of a wooden tool made for the purpose, and rendered the joints water-tight. Under the railway, which was crossed at two points, cast-iron pipes were laid jointed with lead, and a manhole constructed in both cases on the railway at the up side of the crossing.

The fall of the ground was so rapid on the south side of the principal street (Station-road) that the greater part of the houses on that side could not be connected with the 15in. main laid in the street, and were, therefore, provided with a sewer running through the back premises parallel to this, some few of the occupiers having junctions provided in both mains, as the street main was laid sufficiently deep to drain all cellars situated in the front of the houses. The 15-inch pipe sewer in High-street may also be noticed. It runs parallel with the main outfall sewer, while the flow is in the contrary direction. It might seem at first sight more desirable to have carried the main sewer through High-street. The depth of cutting to effect this would have been about 20ft. for one quarter of its length, and nowhere less than 12ft. In ordinary soils it is possible the cost of increased depth of excavation would not have exceeded the cost of the pipe sewers, but in this case, all the houses being built on the surface, and that surface being of such a nature as to vibrate with every passing waggon, the cost of the timber which would have been left in the trenches for the security of the buildings would have soon mounted up to many times that value. The 2-foot culvert along the London-road was carried through quicksand precisely similar to that before described, except that the bed of clay was not so well defined as before. The same means were adopted in dealing with the springs, and the result was, most of the surface wells were dried—a result not at all to be deplored in a sanitary point of view, as they were largely affected by percolations from cesspools, and otherwise contaminated owing to the porous nature of the subsoil; and as the Caterham Spring-water Company have just completed laying their mains through the town, the inhabitants have an opportunity of compensating themselves for the loss of their wells by procuring a constant supply of pure and soft water at a moderate cost. The manholes which were situated at the angles of the sewers were, with one exception, elliptical in shape at the base, major and minor axis, 5ft. and 3ft. respectively. They were constructed of brickwork in cement, and in all cases carried 1ft. below the invert of the lowest sewer connected with them, the bottom being formed of brick-on-edge paving grouted in cement. The manholes we e drawn in at the top to an ellipse, 2ft. 3in. × 1ft. 10in., and were provided with the manhole covers and frames manufactured by Messrs. Sharp and Co., of Lancaster. They consist of a cast-iron framing filled in with blocks of wood. They offer no impediment to traffic, and will no doubt be found to be exceedingly durable. They have, however, one fault, which is, that road grit falls in and is forced down by the traffic between the cover and the frame, so that the former gets jammed tight, and the men, finding they can't lift it by the keys, use a pick to clear the space round the cover, which is apt to injure it. The author thinks this might be obviated by constructing the cover with a flange all round the upper edge. It need only project 3in., and should be roughed on the upper surface. This, he thinks, would remedy the evil. Ventilating shafts were connected with most of the manholes, and were also placed at intervals along the sewer. They were provided with cast-iron ventilating boxes containing charcoal trays. They have a partition in the centre, one side forming a receptacle for road grit, the other communicating with the sewer and provided with galvanized iron charcoal trays. The cover is perforated for half its area only. The trays are connected together so as to be readily lifted out of the box when it is required to renew the charcoal. The pipe sewers were constructed with a vertical drop at each ventilator. This was effected by inserting a quarter circle bend connected with a T-piece, the shaft being carried up with two or three diminishing pieces, according to the depth of the sewer, as shown on the drawing. This is in every way a preferable method to that of breaking the continuity of the pipe sewer and constructing a shaft in brickwork, as is usually done.

The ventilation of sewers by means of charcoal the author believes first took its rise from the investigations of Dr. Stenhouse, F.R.S., who, in 1853, directed attention to the subject of charcoal in connection with the ventilation of impure atmospheres. He showed that charcoal was not an antiseptic, as it was at that time generally represented to be, but, on the contrary, was a great agent in promoting decomposition, from its capability of absorbing large quantities of gas, and retaining it within its pores until it was gradually oxidized. Keeping this principle in view, the author ventures to throw out a suggestion which he cannot help thinking would be worth a trial, and which might be found to increase the efficiency of the charcoal immensely, and render the smallest escape of mephitic gases almost an impossibility. He proposes to use, instead of ordinary charcoal, oxygenated charcoal. If charcoal is exposed to an atmosphere of pure oxygen, it quickly absorbs it, retaining in its pores a quantity equal to 9⅓ times its bulk. The gas, being thus condensed, acts with magnified force in effecting the oxidation of gases exposed to its influence: compared with oxygen in an uncondensed state, *a fortiori*, compared with the oxygen of the atmosphere, which is five times diluted. That this is no mere theory may be proved by bringing sulphide of hydrogen (H S) (a gas once smelt not soon forgotten) in contact with oxygen gas at ordinary temperatures. No action takes place; but if a bit of charcoal which has absorbed the latter gas be introduced into a jar containing the former, it (the H S) is immediately oxidized, sometimes with detonation, water and sulphurous acid being produced. The expense of thus oxygenating even a large quantity of charcoal would be comparatively trifling; and we may conclude that a much smaller quantity of charcoal than is at present used in the ventilators would be sufficient to effect the complete deodorization of the gases. It must be remembered also that charcoal will not part with its absorbed oxygen, except on the influence of heat, or on being placed in vacuo; and we may reasonably infer it would retain its properties a considerable length of time before requiring reoxidization.

The gulleys used have a box for retaining road sand, which is easily removed and replaced, and the gulley traps itself. They are admirably suited for towns, having well paved channels of moderate inclinations, where the old cesspit gulley would be a nuisance. But in situations where much sand is carried down the steep inclines by heavy floods of rain, they are not so well suited, as the boxes soon get full, and any further supplies of sand overflow with the water, and get into the sewer; besides which, sand is apt to find its way into the groove on which the grating frame rests, filling it up, and then making a passage for sand and water outside of the box. Of course, these disadvantages can be prevented by proper attention on the part of the man intrusted with their supervision; but, in the unfavourable situation mentioned, the mischief may be done in one night, and on such nights, too, when it would be unreasonable to expect the most energetic inspector to be out of doors. In the Redhill sewers two or three gulleys were placed in these unfavourable situations, and the consequences were as have been described, and then Mr. Latham, the engineer, recommended catch pits for the sand to be put in at the front of these gulleys, which would obviate the inconvenience arising from sand. The author had hoped to have brought before the notice of the Society a series of experiments on the flow of water in these sewers; he has only been able, however, to conduct very few, as he was called away from Redhill to superintend the new irrigation works at Rugby. He, however, submits the few experiments he did try in a tabular form, and hopes at some future period to be able to bring forward a much more extended series on a similar plan.

Experiments on the Flow of Water in Egg-shaped Sewers, compared with Formulæ.

	i	m	V in ft. per min. Rankine.	Molesworth.	Experimental.	Q cube ft. per min. Rankine.	Molesworth.	Experimental.
Manhole A to B, mean of 3 experiments ...	1/252	0.195	154	157	180	40·81	41·6	47·7
Manhole C to D, mean of 3 experiments ...	1/455	0·29	78	79¾	76	34·81	35·26	33·58

i = height divided by length or sine of the angle of inclination.

m = hydraulic mean depth.

It would seem by this table that the experimental velocities and capacity of discharge approach nearer the theoretical, where the flow of water is slow and the inclination of the bed slight, but the author is very far from wishing to base any definite conclusions on such limited experiments, and will now conclude this paper by giving a detailed statement of the cost of the works.

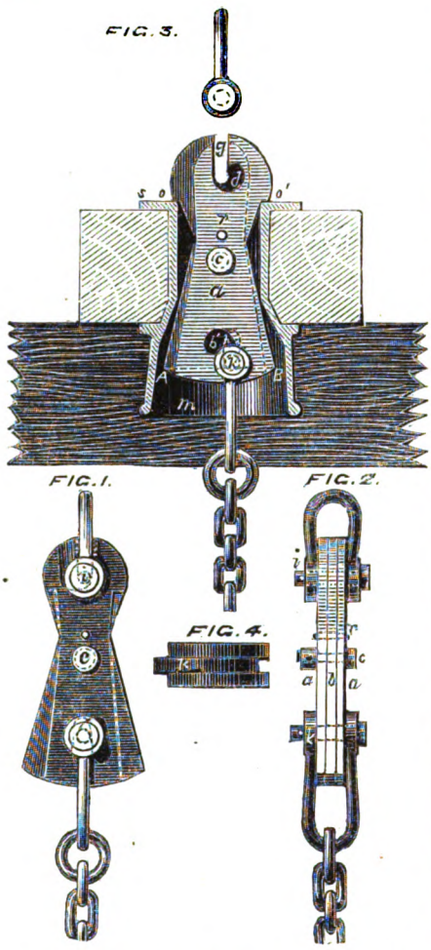
ORMEROD'S PATENT SAFETY LINK.

WE have from time to time placed before our readers various devices for the prevention of accidents at collieries from overwinding. We have now to draw their attention to a very important improvement in this direction, which has been invented by Mr. Edward Ormerod, the engineer at the Atherton collieries. Some time since, several serious accidents from that prolific cause of accident—overwinding—occurred at these collieries. To prevent their recurrence, the proprietors—Messrs. Fletcher and Co., directed Mr. Ormerod to select the most effective apparatus he could find for preventing overwinding. Mr. Ormerod carefully investigated a great many inventions, but with respect to all of them, there was, as he conceived, the serious defect of liberating themselves at the bottom of the contrivance. With the

Digitized by Google

contrary view in his mind, he saw that if they were set free at the top instead of the bottom, nothing but the rope and the shackle at the end need go over the pulley. Accordingly, he set to work to invent an apparatus on this new principle, and, after much patient labour, he has at length succeeded, and the result is the exceedingly simple and thoroughly efficient apparatus we have shown in the accompanying engraving. By so constructing it that it will lock itself when drawn into the cylinder, the inventor has produced an apparatus which accomplishes the three-fold purpose:—firstly, of disconnecting itself with certainty; secondly, remaining behind whilst nothing but the rope goes free; and, thirdly, of catching the cage in falling back again. The invention consists simply of a link or shackle formed of three plates placed side by side, and connected together at a point about the middle of their length by a central stud upon which the plates turn. In these plates slots are formed, in which the shackle pins that connect the rope with the cage are contained. We have a well made working model of the link before us, which we have manipulated over and over again with invariably satisfactory and unfailing results.



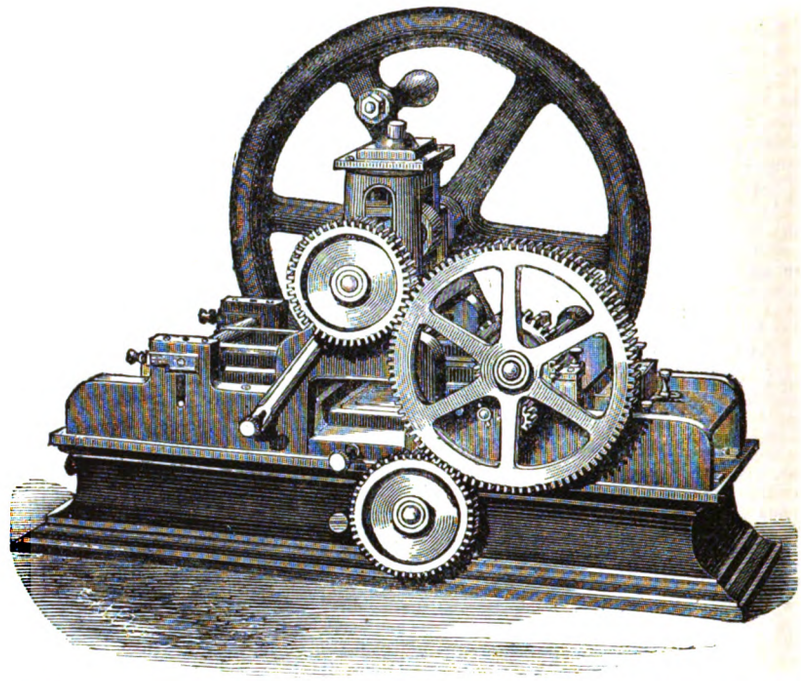
In our engraving, fig. 1 represents a front elevation of the link as it appears when duly connected, in which position it forms a permanent union between the rope and the cage; fig. 2 represents a side view of the same. Fig. 3 represents a front elevation of the link as it appears when the rope is disconnected, and the cage retained upon the top flange of the disconnecting tube. *a a* are the outside plates of the link, and *b* is the inside or intermediate link; these links are placed side by side, and connected together by the stud *c*, upon which the plates turn as on a centre. The two outside plates are provided at the top with curved slots *d d*, each having an opening extending to the edge of the plates, and the bottom slots b^1 b^1 are formed in the plates, which, however, do not extend to the edge, and have no exit for the lower shackle pin. The intermediate plate *b* is also provided with two vertical slots *g* and *h*, the upper slot *g* being open at the top, and the lower slot *b* closed. These slots, when combined in the position shown in fig. 1, are arranged so as to embrace and retain the pin *i* connected with the suspending or winding rope, and the pin *k* connected with the cage, hoist, or receptacle. A small hole *r* which corresponds in each plate (when in the position shown), is filled by a soft metal pin, which is inserted through the plates to prevent them moving without the necessary pressure, and which thus forms a permanent union or link when in this position.

The inclined edge of the intermediate plate *b* projects beyond the edges of the other plates, and in such position the rope and cage are properly connected for working. Should, however, the cage be lifted too high, so as to bring it near the winding pulley, the link enters the cylinder *m* (fig 3), which is permanently and securely fastened at a proper distance between the pulley and the shaft or pit opening, and when the link has been drawn sufficiently through so as to allow the upper end to project above the flange or collar of the tube *m*, the interior surface of the tube *n* will have forced or compressed the edge of the plate *b* level or even with the other plates *a a*, which will cut or break the soft metal pin, and cause the interior vertical top slot *g* to force the pin *i* from the curved slots in the outside plates so as to make all the vertical slots coincide, and one common opening out at the top of the links will be formed, thereby allowing the pin *i* connected with the rope to escape. The catches *o o'* of the links overlap and are caught by the flange *s* of the tube *m*-whereby the release of the cage from the rope, and the retention and safety of the cage are simultaneously effected. When the inclined edges of the plates project above the flange of the cylinder, as seen in fig. 2 (at the time the cage is released), the links become locked in such position, and are retained in and supported by the tube or cylinder until the cage is uncoupled or its weight removed from the links. This locking is effected by means of the pin *k* which enters the vertical slots in the lower ends of the plates when it is forced from the curved slots in the outside plate of the link whilst passing into the cylinder, and is further locked by means of a pin projecting from each side of the middle plate, and which passes along inclined slots into recesses cut in the inside faces of the two outside plates, as seen in the detached view at fig. 4, which is a section through the line A B of fig. 3.

We pass over the numerous trials of this apparatus, which certainly proved its perfect working, but were only experimental after all, preferring to give an instance of its utility which has just occurred in actual practice. This is the grand test of any invention, and we are glad to be able to record an instance in favour of the present one at so early a period of its career. The circumstance in question occurred at the Mesnes colliery, Wigan, where the apparatus has been adopted and was about to be tested. This, however, was accidentally effected before the time appointed, but it proved the efficiency of the link beyond a doubt, and removed the necessity of any further trials. It appears that the eccentrics of the engine got loose while the engine was at full speed. The engineman thus lost control of the engine, which ran the pulley in at full speed. The rope was released and the cage remained suspended, and thus a serious accident was prevented. We consider Mr. Ormerod's invention to be a sound, practical piece of mechanism. As such, it cannot fail to recommend itself to every colliery manager, and to come into general use, and cause accidents from overwinding to be numbered with things of the past.

MACHINE FOR PRINTING WITHOUT INK.

BY M. LEBOYER.



PRINTING WITHOUT INK.

WE have lately examined a clever mechanical adaptation of the well-known principle of the manifold writer to printing purposes. It is a small machine worked by hand, and by which printing is effected with great rapidity without ink, and without any previous preparation except, of course, setting the type. It is the invention of M. Gustave Leboyer, and attracted considerable attention in the Paris Exhibition last year. We saw it at work at the office of Mr. J. M. Powell, 3, Bouverie-street, Fleet-street. Its general construction will be seen in our engraving, which shows a perspective view of the machine. At the right end of the apparatus is a box in which the cards are deposited in a pack, a small weight being placed on them. They are fed forward, one by one, from the bottom of the pack, between two rollers, over which pass endless tapes. The types are set in a platen, and inserted through an aperture in the side of the machine at the centre. As each card reaches this point an eccentric on the shaft of the flywheel presses it down upon the type, and as a piece of carbonized paper is interposed between the type and the card, a correct impression of the former is left on the latter. The printed card passes on and is delivered at the end of the machine opposite to that at which it entered. The carbonized paper is a long strip and is wound on a roller placed to the right of the cam shaft, the end being secured to another roller to the left of this shaft. The latter roller unwinds the paper from off the former progressively as each card passes over the platen, so that a fresh surface is continually presented to the type. The printing we saw done was decidedly good, the mechanical arrangement working well, and the result being a sharp black print. We saw some excellent specimens of colour printing, which were very effective. The machine is turned by hand, and prints at the rate of about 100 cards per minute. Not cards

Digitized by Google

alone, but circulars and bills may be printed by these machines, of which we saw two sizes—each for a different purpose.

GOLD DISCOVERY IN SOUTH AFRICA.

HERR MAUCH, the German traveller, has arrived in Natal. He asserts that goldfields, believed by him to be richer than those of California or Australia, exist in the interior. According to his statements the locality of this auriferous region is precisely identical with the description given by Dr. Livingstone in his first book of travels, and the present discovery may be regarded as being the confirmation of rumours and the justification of convictions that have prevailed from the earliest times. Mr. Mauch tells us ("Natal Mercury") that he has seen two goldfields—the northern one being of indefinite extent, and lying much nearer the Zambesi than the other. This latter one is situated about 900 miles from Natal in a north-westerly direction, beyond and to the west of the limits of the Transvaal Republic. It is in the country formerly ruled by Sekhomo, a runaway chieftain, whose place is now filled by Machin, under the suzerainty of Moselekatse. As the former chief can muster 10,000 warriors and the latter 40,000, it is evident that the chief obstacle in the way of any gold-working movement rests in them. The country itself is tolerably healthy and well watered. The geological character of the district is represented by metamorphic rocks, with slate, and the other usual indications of auriferous wealth. Vegetation is not luxuriant. In the immediate neighbourhood of the goldfield, which Mr. Mauch estimates to cover a tract of twenty miles broad, and sixty miles long, there are not many natives. When the explorer saw the white reefs of auriferous quartz glistening in the sun, as they cropped out here and there, he was startled by the conception of the wealth which he firmly believes those reefs to contain. Thousands of holes, some 10ft. deep, give evidence of old native workings, and bear out Dr. Livingstone's remark about the gold washings carried on in wooden bowls by the Kaffirs in times past. Mr. Mauch brings with him about twenty specimens. Those that are auriferous consist of pale quartz, containing minute particles of pure gold. Several of them are of iron and lead ores, and some of them come from the Transvaal Republic. It is difficult as yet to say what the upshot of these disclosures will be. Mr. Mauch explored the country in question in company with Mr. Hartley, an old and well-known elephant hunter, and, in justice to that gentleman's exertions and services, he considers that he is bound to require some recompense in his behalf. Mr. Mauch himself has no interest in the discovery, he says, beyond the scientific distinction it may bring him. He is accredited and commissioned by the Geographical Society of Gotha to do a certain work,—namely, to traverse Africa westward of the lakes from Natal to the Mediterranean, and to the accomplishment of that grand purpose he has devoted his life for the next few years. It remains to be seen whether the exact situation of the goldfields will become generally known by means of the information accorded on payment of the required reward, or by means of further private adventures. Our impression is that, as the locality of the goldfield is known already to one or two Englishmen resident in the Transvaal Republic, the discovery will be developed in the first instance by means of private expeditions. It cannot be denied that considerable risk will attend such movements, but the prize to be won offers an overpowering inducement to the adventurous spirits abounding amid the wild scenes of the interior.

NATIONAL BOILER INSURANCE COMPANY.

WE have before us the annual report of Mr. H. Hiller, the chief engineer of the National Boiler Insurance Company. We are happy to learn from it that, although the general depression of trade and manufacturing industry has been even more severe than in the preceding year, the Company's connection has steadily and considerably increased. This is the best testimony to the value of this and kindred companies. Mr. Hiller embodies in his report practical information of a character likely to be useful not only to boiler owners but to their engineers, so that their attention may be directed to the superior advantages of first-class apparatus, and to the necessity for that constant and careful attention to the condition and working of boilers which cannot be safely omitted.

The report is divided into three portions; the first relating to the defects met with in the boilers inspected; the second containing a few practical remarks on boiler construction; and the third a summary and report of the boiler explosions which have been reported to Mr. Hiller during the past year. The chief engineer states that many cases of dangerous external corrosion have been reported which were due to dampness of flues or leakage at riveted seams, the boiler plates being thinned where in contact with the brick seatings. Also leakage at the blow-out pipe joint, careless slaking of ashes, or leakage at mudhole joints, the corrosion being hidden by the excessively thick brickwork of the front cross wall. External moisture, causing wasting of the plates in contact with the brickwork at sides of boiler, and neglected leakage from the fittings. Some of the boilers inspected were found dangerously weakened by internal corrosion, the plates in some cases being reduced to less than half their original thickness. In one instance, the flue tube of a second-hand boiler was so much weakened that, on being submitted to the hydraulic test, it collapsed at a pressure little beyond that to which the safety valves were usually loaded. Numerous cases of deep grooving were met with in the end plates of internally-fired boilers, at the edges of the angle irons of upper part of tubes, and, in some instances, the plate was quite broken through.

Under the head of defective fittings, Mr. Hiller observes that no fitting attached to boilers requires more constant attention and frequent testing than the water gauges, and attendants cannot be too strongly impressed with the necessity for special care on this point. It is only too true that gauge fittings with no glass, or taps so leaky that the gauge cannot be tested, and floats so stiff as to give no reliable indication, are frequently met with; and, occasionally, instances of great ignorance or gross recklessness on the part of the attendants or of the owners of the boilers. The safety valves of many boilers were found excessively overloaded in various ways. Others were corroded quite fast through neglect. In one instance the valve lever of a new boiler was actually held down by a prop placed against the floor above. The danger incurred in such cases is too evident to require comment, and we can only suppose that explosion was arrested by the timely visit of the inspector.

Under the second head of the report, boiler construction, Mr. Hiller gives some sound practical information, insisting on points which are but too often regarded as of minor importance, both by makers and users. We shall refer again to these points in a future number, as they are somewhat lengthy for our present purpose. Passing on to the third head, boiler explosions, we find the remarkable statement that a boiler under the care of company has actually exploded! This is unprecedented; it is the first accident which has occurred to a boiler under the company's inspection, and forms the exception which goes to prove the general rule of safety. We are glad to be able to state that the explosion was not of a very severe character, as the boiler was not moved from its seating, nor was anyone seriously injured. We cannot take this accident as militating against the interests of the company when we find that although generally the inspector's suggestions are well received and appreciated, yet in some cases, through misapprehension of their object or meaning, or of the danger which is pointed out, they are not attended to. Mr. Hiller states that in a number of instances this neglect has been followed by the accident or damage it was wished to avoid. We need not follow Mr. Hiller through the list of explosions for the past year; they have for the most part appeared in our columns from time to time. The list is a long one, and when contrasted with the immunity enjoyed by those whose boilers are under inspection, the value of such companies as the National Boiler Insurance at once becomes apparent. We trust that boiler owners will, by their voluntary action, procure such inspection of their boilers as will render unnecessary that Government interference which we have so often recommended for adoption.

INSTITUTION OF CIVIL ENGINEERS.

AT the monthly ballot of the above institute the following candidates were balloted for and duly elected as members:—Messrs. W. C. Barton, James Bower, W. W. Clark, R. S. Clayton, F. J. Dennys, James Mathias, John Paton, G. L. Reid, and David Richmond; and as associates:—Messrs. H. G. Anderson, F. C. Barron, W. T. Blacklock, W. R. Browne, R. H. Brunton, C. T. Casebourne, R. G. Clutton, C. H. Croudace, H. A. S. Fenner, W. R. I. Hopkins, W. S. Howard, Alfred Longsdon, Robert Reynolds, F. W. Robinson, R. B. Smyth, William Sykes, J. J. Wallis, and D. W. Young; and Sir A. W. Mackworth, Bart., R.E. It was announced that the Council, acting under the provisions of Section IV. of the Bye-Laws, had recently admitted as students of the Institution, Messrs. J. A. Carfrae, J. M. Gibson, C. S. Harris, G. E. Page, and F. G. Wynne.

ABYSSINIAN EXPEDITION—WATER SUPPLY.

WHEREVER in the progress of the expedition water springs are to be met with, and the superincumbent material is capable of being pierced, Mr. Norton's pumps will furnish the readiest, cheapest, and in every way the best source of water supply; but these conditions are not in all cases to be calculated upon with confidence, and other sources of supply are accordingly of vital importance. Assuming that the expedition will keep its communication with the coast open, and that the means of transport can be found, the apparatus for distillation in the vessels lying near Annesley Bay will give about 80,000 gallons per day. There are 78 vessels, including transports, furnished with condensing apparatus. Some of the transports are only capable of distilling a small quantity—from 30gals. to 200gals. a day—but many of the larger vessels are capable of much greater performances. The "Hydrabad" from Bombay is equal to 10,000gals. a day, the "Semiramis" condensing vessel 4,000gals., the "Californian" and the "West Indian" 2,780gals. each, and many other vessels 1,200gals. each, and upwards. It is to be hoped that the supply by the pumps may prove sufficient, as the cost and tediousness of water supply from the coast is of course great and growing. However, here is a resource should the wells fail in their supply.

PEAT FUEL.

THE practical application of peat as a fuel for steam purposes still continues to receive attention in several quarters. The question, however, appears to be surrounded with difficulties, as, after years of trial, its definite solution has not been arrived at in England, although in Ireland it is largely manufactured by Mr. C. Hodgson, both for steam and household purposes. There is not in England — so far as we can find—any establishment where the manufacture of peat is carried on upon a commercial scale in a condensed form suitable for steam purposes. We have been told by some, that condensed peat is being made in some parts, but is of such value in the form of charcoal for the manufacture of iron and steel, that none can be spared for steam fuel, the ironmasters taking all they can get, at high prices. We know that peat, properly prepared, is invaluable to the iron smelter, but were there a brisk trade in peat manufacture, there would be enough for all purposes. The fact is, we do not appear to have quite arrived at that point at which the manufacture can be called a commercial success. It was nearly done at the peat works, at Horwich, but, just at that point, we believe, the works were burnt down, and the company has become extinct. Another company, however, we hear, is now engaged in practically developing the question, and, with Mr. W. Austin as their engineer, are erecting machinery for producing peat fuel in large quantities for land and marine engines. We are informed that the works of this company will shortly be opened, and that public trials of the condensed peat will be made in a few weeks. We shall then hope to place our readers in full possession of all particulars. For the present, we can only say that having examined some of the peat produced, we find it to be of excellent quality, and apparently well adapted for use as a steam fuel.

ROYAL MICROSCOPICAL SOCIETY.

AT the ordinary meeting of the above Society held on Wednesday week, Mr. James Glaisher, F.R.S., President, in the chair, one new Fellow was elected, and a large number of presents to the society were announced. A paper was read by Major Ross, R.A. on micro-crystals, and iridescent Films, obtained by the use of the blow-pipe; the subject—which was illustrated by experiment and by specimens exhibited under the microscope—gave rise to an interesting discussion, in which Messrs. Charles Brooke, F.R.S., Jabez Hogg, F.L.S., and H. J. Slack, F.G.S., took part. A paper was also read by Mr. Jabez Hogg, on the lingual membranes of mollusca, the subject being illustrated by a series of beautifully executed coloured drawings. The thanks of the meeting were presented to the readers of the papers, and the President announced that the annual soiree of the Society would be held on the 22nd.

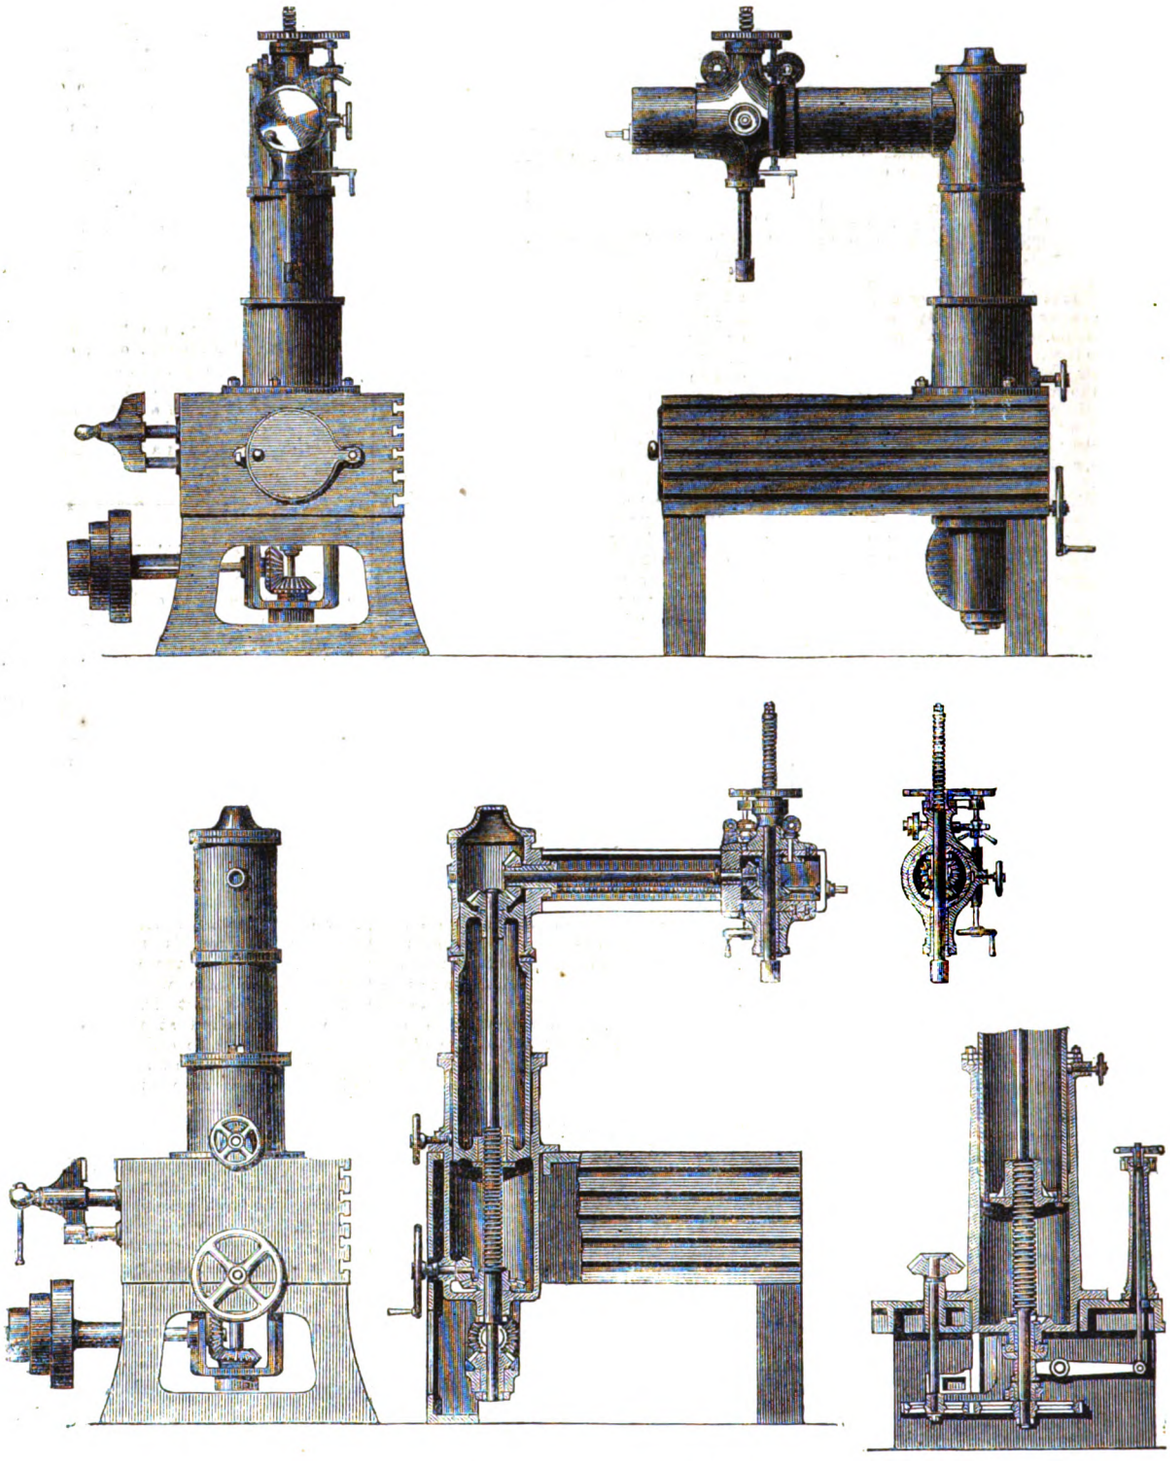
ALLEY'S RADIAL DRILLING MACHINE.

MANUFACTURED BY MESSRS. NEILSON BROTHERS.



RADIAL DRILLING MACHINE.

THE above engraving represents a radial drilling machine, which has lately been introduced by Messrs. Neilson Brothers, of Glasgow, and was designed by Mr. S. Alley, of that firm. It possesses some novel features in its construction, and doubtless will prove itself a very useful tool, especially for light work, for which, probably, it will be most extensively employed. The chief peculiarity in the machine is that nearly all the gearing is enclosed within the hollow pillar and radial arm, thus protecting it from the dust and from contact with surrounding objects, whilst the tool as a whole is rendered very compact. The pillar, which is of the telescope form, is raised and lowered by hand in the smaller machines, but for larger sizes Mr. Alley has adopted an arrangement which is represented in the sectional view. The wheel and screw on the top of the vertical pillar on the left-hand side of the main pillar is employed for raising a coupling on the driving shaft, by which means the lifting screw is coupled to it. The drill spindle is provided with a self-feeding motion, which can be engaged and disengaged at pleasure by means of a friction clutch. The other parts of the machine are so clearly shown on the woodcut, that a further description is not required.

The number of visitors to the Patent Office Museum, South Kensington, for the week ending April 11, was 3,662; total number since the opening of the museum, free daily (May 12, 1858), 1,274,425.

MACHINERY FOR CUTTING CORKS.

CORK cutting would seem to be a simple operation, but there are so many points to be attended to that those who best know what the work is, will admit that it requires no ordinary amount of ingenuity to design a machine which shall meet all the requirements of the case. We, however, illustrate a new cork cutting machine, which is said to fulfil every requisite condition, turning out its work with perfect accuracy and great rapidity. The inventor is Mr. J. W. Dudley, of Drummond-road, Bermondsey. By these machines the sheet of cork is first cut by a circular knife into strips the width of the length of the cork. It is then fed endways to the machine. The first knife cuts off a square which rotates as the segmental knife passes over it, and

CORK CUTTING MACHINE.

BY MR. DRUMMOND.

FIG. 1.

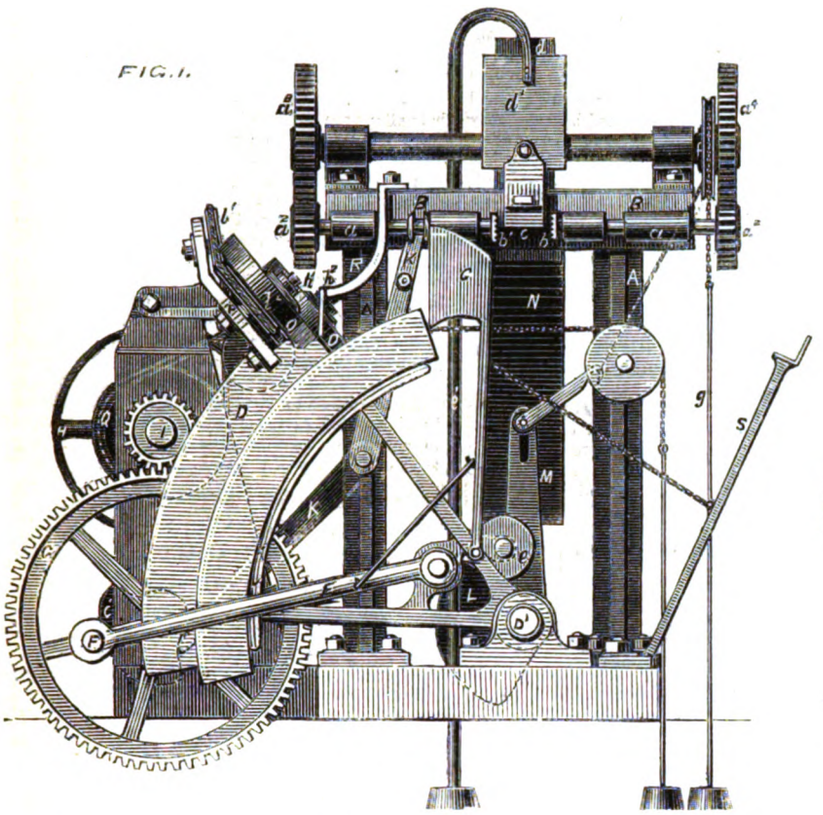

FIG. 3.

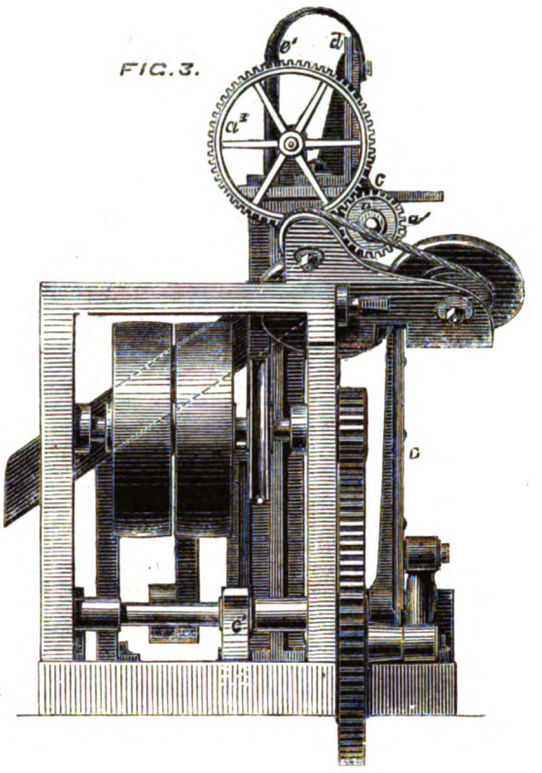
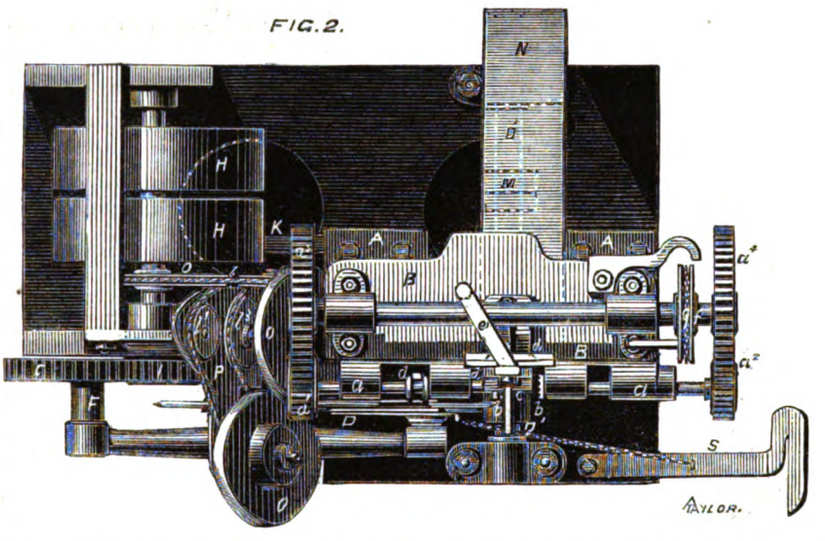


gives it a circular or an oval form as required. The corks leave the machine complete. The economy of this manufacture is apparent in various ways. First, in time and cost of labour; an ordinary day's work for a man cutting corks by hand is from ten to twelve gross, whilst with the machine a boy turns out eighty gross in ten hours. Next there is an economy of material, for the shavings are as thin as they well can be, and thus there is less material cut to waste; the number of corks cut from a given weight of wood is much greater than by any other process.

Passing on to the details of the machine itself, it will be noticed that our engraving shows at fig. 1 a front view, and fig. 2 a plan, and fig. 3 an end view on the side of the driving gear. A A are standards mounted on a bed plate at each end of the machine, on which standards is bolted a plate B carrying the adjustable bearings a a of the dog b b^1, and between which the strip of cork is gripped on being fed to the machine by hand. The strip of cork is previously cut of a width corresponding to the length and also to the thickness desired to make a certain sized cork. The spindles of dogs b b^1 carry pinions a^1 a^2 at either end, gearing with toothed wheels a^3 a^4, mounted in bearings on plate B. After the strip is gripped by the dogs b b^1, it is immediately severed by a knife C moving across the face of the machine and suitably attached to a second knife and frame. The knife C which is fitted to move in close proximity to the bearings a a is adjustable together with the paring knife D, according to the size of cork desired. The knife C in its forward motion severs a piece of cork from the strip of sufficient size for a cork, the diameter of which is regulated by a gauge c rising and falling in a guide d at the upper part of the machine. The piece of cork in the form of a parallelopiped being gripped by the dogs b b^1, is then subjected to the action of a second knife D of segmental form mounted in bearings on the bed plate of the machine. This knife has reciprocating motion imparted by the aid of a connecting rod E connected to a crank pin F of a toothed wheel G, to which motion is communicated from the driving pulleys H and pinion I. The shaft of the wheel G is provided with a cam G^1, by the aid of which one of the dogs, b^1, is operated for seizing or releasing the cork when fed into the machine; this cam G^1 acts on a counterbalanced lever arm K mounted on the framing A, its upper end being connected to a collar d formed

FIG. 2.



on the spindle of dog b^1, so as to effect its sliding movement in one or other direction for gripping or releasing the piece of cork.

Fig. 1 shows the position of the knives C D, and cam G^1 at the moment of commencing the forward movement for cutting and shaping the cork, the gauge c being at same time brought to its lowest position in contact with the strip by the aid of slide d^1, the rising and falling movement being operated by a cam L keyed on the knife shaft D^1, through the aid of the truck roller e carried on the rod e^1 of slide d^1, the rod being weighted. In this position, the cork being held by the dogs b b^1, is first severed by the knife C in its forward motion, and the pinion a^1 of dog b^1 being thrown into gear with weel a^3 by the action of cam G^1 and lever arm K, both the dogs will immediately rotate with the piece of cork between them during the whole of the forward motion of knife D, so as to pare off the angles and produce a cylindrical cork. Rotary motion is imparted to the dogs b b^1 by means of a lever arm M fixed on the knife shaft D^1, and connected to a pulley f mounted on the wheel shaft of a^3 a^4 by a chain and counterbalance g. The rotary motion of the dogs b b^1 continues until the knife has completed its oscillating forward motion, after which and during the return motion of the knife D the projecting part of the cam G^1 acts on the lever arm K for drawing back the spindle of b^1 by the aid of collar d, when the dogs will no longer turn, and the rounded cork will be released and fall into the shoot N.

We may here observe that immediately the knife C has severed the square of cork from the strip, the cam L on the knife shaft D^1 raises the gauge c by the aid of the slide d^1 and rod e^1, so as to permit of the free rotation of the piece of cork held by the dogs. In order to keep the oscillating knife D in a constantly sharpened condition, two grindstones O O are mounted towards one side of the machine, in such position that both edges of the knife moving between and at right angles to the direction of motion of stones may be constantly in contact with them during the whole time of the oscillation of the knife in both directions. These stones are mounted on stud pins h^1 h^2, fixed on a plate P bolted to the frame in which the driving gear is mounted. The

Digitized by Google

stones receive motion from a pulley Q mounted on the driving shaft by means of an endless band encircling the pulleys l l^1 l^2 l^3, the two latter being fixed on the spindles carrying the stones. R is a guard iron fixed to the top plate B, its lower end being in close proximity to the face of knife D, and serving to prevent any cuttings of cork liable to be carried back with the knife from fouling the stones. The backward movement of knife C is limited by a cord or chain, so as to prevent its coming in contact with the collar d of dog spindle, it being necesssary to adjust the knife as close as possible thereto for cutting small corks. It also permits of the oscillating knife D moving back sufficiently to sharpen the whole length of its curved edges. S is a rest supported on an arm fixed to the bed plate of the machine, on which the operator places the strip of cork with the end slightly projecting for the knife C to sever in its forward motion whenever there may happen to be any imperfection in the cork strip it is desired to remove before presenting it to the gripping dogs.

As already mentioned the corks instead of being turned cylindrical may be made of taper form by slightly lowering and altering the direction of one of the dog spindles b by the aid of the adjustable bearings a a. The knife frame D can also be made to move to and fro on its shaft, if desired, in order to produce a cork of oval form. A simpler mode of effecting the same purpose consists in making the bearings a a, carrying the dogs b b^1, to move slightly backwards and forwards by means of a cam mounted on the shaft before mentioned, as giving motion to the dogs, a projecting stud or pin on the bearing a in contact with the cam being regulated so as to give more or less motion for producing a more or less oval cork.

ON ALLOYS AND THEIR USES.*

By PROFESSOR A. MATTHIESSEN, F.R.S.

THE object of this discourse was to show experimentally why alloys are used in preference to their component metals. Alloys may be, chemically considered, divided into three classes:—1. Chemical combinations. 2. Mechanical mixtures. 3. Solutions of the one metal in the other which has become solid, or for shortness sake, solidified solutions of the one metal in the other. Under the term chemical combination such alloys may be considered which are the result of the combination of two metals when these unite together with great energy and evolution of heat, producing an alloy the physical and chemical properties of which we cannot foresee. As an example of such alloys those of gold, with tin, lead, or zinc may be quoted; for if to melted tin, lead, or zinc, gold may be added, the two metals unite together with great energy and produce an alloy which is exceedingly brittle and totally unfit for practical purposes. It is for this reason that the more expensive metals, silver and copper, are used for alloying gold for the purposes of coinage, &c.

With regard to such alloys which may be looked upon as mechanical mixtures, like oil and water, or rather as ether and water, for no two metals are known which, like oil and water, do not dissolve at all in one another, but a few metals are known which, like ether and water, dissolve slightly in one another, for ether will dissolve a certain amount of water, and water a certain amount of ether. If ether and water be mixed together, say in equal parts, two layers will be formed, the top one being ether containing a little water, the lower one water containing a little ether. Two metals, for instance, which behave in exactly a similar manner to ether and water are lead and zinc, for lead when fused with zinc will dissolve 1·6 per cent. zinc, and zinc in its turn will take up 1·2 per cent. lead. If these two metals be fused together, say in equal parts, they will separate into two layers, like ether and water, the top one, being the specifically lighter, zinc, with a small per centage of lead, the lower one lead, with a small percentage of zinc. If such an alloy be made and cast in a mould, the difference in the behaviour of the two ends may be easily shown; for the top one is so brittle that it cannot be bent without breaking, whereas the lower one may be bent with ease. Such chemical combinations and mechanical mixtures are, however, comparatively rare; and for alloys in common use, practice has almost invariably chosen such alloys as may be considered as belonging to the third class, rejecting those of the first and second as worthless for practical purposes.

* Read before the Royal Institution.

Under the term solidified solutions of the one metal in the other, such alloys may be considered, which, like the chlorides of potassium and sodium, when fused together, produce a mass having some of the physical properties totally different from those of the component salts. It cannot be assumed that the chloride of sodium enters into chemical combination with the choride of potassium. One important property of a solidified solution is, that the components are homogeneously diffused in one another, so that even under the most powerful microscope they can no longer be distinguished from one another. Alloys are used because they possess certain physical properties to a far greater extent than their component metals. The physical properties may be divided into two classes. 1. Those which in all cases are imparted to the alloy, approximately in the ratio in which they are possessed by the component metals. 2. Those which in some cases are, and in others are not, imparted to the alloy in the ratio in which they are possessed by the component metals.

To the first belong specific gravity, specific heat, and expansion due to heat. It is easy to show this experimentally; the specific gravity of an alloy may be shown to be equal to the mean of those of its component metals, by hanging on the one side of a balance the alloy and on the other side the metals composing it unalloyed, and then placing them both in water. The specific heat of an alloy may be proved equal to that of its components by placing the alloy and its components in boiling water, and then in equal volumes of cold water; when the rise of temperature in the two cases will be found the same as may be shown by a differential-air thermometer. A brass bar placed in any apparatus for showing expansion by heat is seen to expand exactly as much as a composite bar, of which one portion is of copper, the other of zinc. The length of the zinc portion being proportional to the amount of zinc in brass.

To the second class of physical properties belong, conduction for heat and electricity, hardness, tenacity, &c. As a basis for the conclusion which will be drawn, the electric conducting power for alloys may be taken. Researches into this subject have shown that when tin, lead, zinc, or cadmium are alloyed together, such alloys conduct electricity in the ratio of the relative volumes of the component metals, whilst in all other cases no such simple relation exists between the conducting power of the metals and their alloys. If, for instance, gold be alloyed with silver, say in equal volumes, the conducting power of an alloy will be 15, that of silver being 100, and that of gold 80. If curves be drawn to represent the conducting power of different series of alloys, three typical forms will be observed; the first represented by nearly a straight line, the second by the letter L, and the third by the letter U.

Wiedemann and Franz have proved experimentally that the values obtained for the conducting power of metals and alloys, for heat and electricity, are identically the same; and the truth of this statement may be shown by the following experiment:—If bars of gold and silver and some gold-silver alloys be fixed so that one end of all of them is in a hot-water box and the other end in the bulb of a small air-thermometer, the depression in the columns of the liquid in the tubes of the air-thermometers will indicate the relative conducting powers (approximately) of the several bars; and if through the tops of the columns of liquid a line be drawn, such line will form a curve similar to that referred to as obtained for the electric conducting power.

That this is true is thus shown:—By the side of this apparatus is placed another of this construction:—Into the bulbs of several air-thermometers are fixed wires of the same size and length, and of the same materials as were used in the heat-conducting experiment. One end of each wire is soldered to one thick copper wire, and the other end to another similar wire. These two wires are connected to the poles of a battery. The current will then divide itself, and a portion will pass through every wire proportional to the conducting power of that wire. This current will heat the wire and cause the liquid in the tubes connected with the air-thermometers to descend, and the line drawn through the top of the columns will be nearly similar to the curve already mentioned, which is formed by the bulbs in which the heat-conducting bars are fixed.

The analogy between the relation existing in this case and in some others may be shown experimentally as follows:—

Sonority.—When bars of alloys and their component metals are struck, a great difference will be found in the note produced; and in almost every case where the experiment ha been made, the most sonorous alloy was found to correspond in composition approximately with that at the turning point of the electric conducting power curve.

Tenacity.—When wires of the same diameter of metals and alloys are broken by traction, those of the alloys will require a much greater force than their component metals; and it may be deduced from what is known, that those alloys the composition of which corresponds to the turning point of the conducting power curve are more tenacious than any other alloy composed of the same metals.

Elasticity.—When spirals of wires of metals and their alloys are weighted to an equal extent, the alloys will be found on removing the weights to possess the property of resuming their original form in a much higher degree than their component metals. Here again the alloys corresponding in composition to those of the turning point of the conducting power curves are the most elastic.

From what has been said, and from the experiments described, the conclusion may be drawn that the chemical composition of the practically-used two metal alloys correspond to those situated at the turning points of the heat and electric conducting power curves, and that if a two-metal alloy of a special physical property be required, it would be as well to try that alloy the composition of which would correspond to the turning point of the curve representing the electric conducting power of the alloy of the two metals.

AERONAUTICAL SOCIETY OF GREAT BRITAIN.

(Concluded from page 280).

THE discussion on Mr. Alexander's paper was opened by Mr. Wenham, who said:—The mode shown by the writer of the last paper of estimating the force of the bird's wings, appears to be quite reasonable. It is certain that the force exerted during the downward stroke cannot much exceed the weight of the bird. If the data are taken from the largest bird that I have noted, viz., the pelican, in which the number of the wing strokes per minute can be easily counted, they will stand thus—Number of strokes per minute, 70; arc of vibration at middle of wing, 2ft.; weight of bird, 21lb. These three quantities multiplied together will give 2,940 foot-pounds, or 1-11-horse power, or about half that of a man. In my first essay, read before this Society, I reckoned the power exerted during the flight of a pelican in a different manner to this, and the results of the two calculations agree very nearly. I do not see, according to this simple and obvious mode of reasoning, that the power of the bird in flight can possibly exceed, and it probably falls far short, of the quantity named. The impulsive force of a bird's wing being intermittent, considerable weight is absolutely necessary for flight, and were the creature lighter than its bulk of air, it could not fly at all; but the power is accumulated in the body, as in the flywheel of a steam engine, to be subsequently made available during the cessations of impulse. Consequently, by means of this stored-up power, the bird can, with motionless wings, glide long distances upon its aerial support, till its previously acquired momentum is expended. When the requisite speed for the supporting power of flight is once obtained, it is instructive to note, in the case of sea birds, how little the loss of power from the friction and yielding of the air must be, for after the bird has darted suddenly down, so as to touch the waves, the velocity acquired by its descent and the momentum due to the weight of its body carries it up again, without a movement of its pinions, to near its original level.

On various occasions, members of our Society have urged the importance of defining a law by which to estimate the absolute forces and conditions required to perform flight before any contrivance made without principle can be successful, but ere the discussion has come to maturity, and science has determined the conditions, practice has outstripped its preceptor, and the flight of man has become a fact of the day. I have further to state that the honour of this discovery is to be credited to one of our own countrymen and a member of this Society. Legends have reached us of men having performed flight in other countries—the Marquis of Bacqueville, at Paris, and Deger, of Vienna—but in both these cases the experimenters launched themselves from lofty eminences. This was not strictly flying but the mere expenditure of force from a falling body, and serves no other useful purpose but to demonstrate the hazard of such feats, the first of these gentlemen breaking his

Digitized by Google

leg on his descent, and the second eventually meeting with an accident that terminated fatally. But within the last few weeks, Mr. Charles Spencer has succeeded in taking short flights of 100ft. from level ground by a machine of his own invention and construction, and entirely by muscular force. The time since the realization of this fact has been so short, that it was found impossible to prepare the diagrams and models for illustration this evening, but Mr. Spencer will give personal demonstrations at our forthcoming exhibition at the Crystal Palace, as far as the limits of the ground will permit, with improved apparatus. I look upon this achievement as being something more than the first steps of infancy, for it has overcome what, to me, has been an almost insuperable difficulty—that of making the first start. This being accomplished, perfection will rapidly follow. I may state, in conclusion, that from early youth Mr. Spencer's mind has been directed to the subject of aeronautics. He is son to the well-known Mr. Spencer, the solicitor, who accompanied Mr. Green in some of his aerial excursions. This celebrated aeronaut is also the godfather of the present Mr. Spencer, who possesses the gift of mechanical construction which has enabled him speedily to carry his experiments into successful practice.

The Duke of Argyll remarked that the meeting would have been better satisfied had Mr. Spencer himself been present.

Mr. W. F. Brearey next read a communication from Mr. Artingstall, of Manchester, detailing the construction of his flying engine, illustrated by a diagram, which after describing, he writes:—"I find that the rising of the wing gives far greater hold upon the air to the down-stroke than if the wings were elevated, and allowed to be still, and then suddenly driven down; it appears as if a wave of air follows the wing in its ascent, which is caught and taken advantage of by the down-stroke before it can make its escape. From my present view of this subject, I believe that the up and down-stroke of a bird's wing are so dependant upon each other, that the two are essential to produce one complete pulsation, &c., the unbroken succession of which causes steady buoyancy or uniform progressive flight, and enables the bird to maintain its equilibrium in so subtle and light a medium as air, although the buoyant or propelling power of the wings may not be operating in a line with the centre of gravity. This is an astounding wonder, and seems to be at variance with all our theories of the properties of matter and motion. Take, for example, the bat, which has no tail, and a great expanse of wings that vibrate above and below the centre of gravity, yet, when the wings are propelling above, the head is not depressed; neither is it elevated when they are propelling below the centre of gravity, and the animal, if it pleases, can progress as steadily as any bird; indeed, some of the larger species of foreign bats are said to float with all the ease of a large and long-winged bird. If there were not some strong steadying power, the bat would be more erratic in its flight than a common rocket without a stick, or an elongated solid bullet shot from a smooth-bored gun. How is this wonderful steadying power produced? for, according to the common theory of resistance of fluids, a bird in the air represents the most delicate balance that can be imagined, the body being its centre, and the two wings the arms or scales; therefore, the least power applied above or below to one wing more than to the other would instantly destroy the equilibrium. It may be said, that a bird feels when it is balanced; perhaps so, but one thing is certain—that no machine constructed by man could do likewise; but a bird not only represents a balance transversely, but longitudinally; in this case, the wings are the centre, and the head and tail the arms or scales of the balance.

I find great difficulty in managing compressed air; the power is either too much or too little. I shall have to make a regulating valve. In one experiment the power turned on was not sufficient to cause flight, but by a very little movement of the tap which supplies the air the engine made a sudden bound into the air, and dashed itself against the opposite wall. There are two questions respecting flight, which may be of great importance to the Aeronautical Society, and which I have omitted in my former communications.

The first is this. If the two great pectoral muscles that depress the wings of a bird are so prodigiously stronger than the muscles that elevate them, how is it that the vibrations are apparently equal? I have endeavoured to account for this by reaction, not by compressing the air underneath the wing, but by the succeeding wave of air, &c. The second question is, are the electric or calorific conditions of the air materially altered by the vibration of a bird's wing. We must not be too sanguine that flight is purely a mechanical operation, entirely dependent upon the inertia of the air. In conclusion, allow me to remark that the great problem of flight can only be solved by experiment: it is beyond the powers of mere college or school mathematicians, however profound, and can only be dealt with by the experimental philosopher; that is, a man who can put in practice his mathematical theories. A Newton, a Watt, or a Faraday has not yet appeared in aeronautics.

This closed the business of the evening, when the President remarked that the next meeting would be held at the Crystal Palace, where a number of models would be shown, and some practical experiments, and amongst them this gentleman flying. The Society had provided refreshments for the members and their friends, who agreeably passed the remainder of the evening in conversation.

VARIABLE CUT-OFF STEAM ENGINE.

AT the meeting of the Massachusetts Institute of Technology, held March 5, Mr. Horace McMurtrie read a communication on a variable cut-off steam engine, exhibiting a working model driven by steam. It is of the class known as variable cut-offs, having a peculiarity of valve motion and regulation invented by Mr. William Wright. He made some general remarks on steam valves for controlling the admission of steam to the cylinder, from the earliest automatic valve gear to the present system of working steam expansively, and the variable cut-off, the last being of very recent date. With the fixed cut-off, the uniformity of speed was maintained by means of a governor which virtually contracted or reduced the steam passage, not reducing the volume of the steam as the load on the engine decreased, but impairing its vitality, producing the effect known as wire drawing. The nearer an engine approaches the following conditions, the more economical and perfect will be its operation:—1. When first admitted to the cylinder the steam, under all conditions of load, should be the same pressure as that is in the boiler, and so continue until cut off. 2. The variation in the load should be communicated to the cut-off apparatus as quickly as possible. 3. The process of cutting off should be completed in the shortest time possible. 4. Uniform speed should be maintained—the last being of special importance. The inventor claims to have fulfilled these conditions in the engine exhibited, securing also strength, great simplicity, perfect regulation of speed, and economy of fuel, to a greater extent than in previously constructed engines.

The general features of the engine are as follows:—the steam is admitted on the side of the cylinder by two separate balanced poppet valves, which are operated by the governor alone, without the aid of belt, crank, or eccentric, in the following manner. The steam valves are horizontal, the spindles terminating in a steel block, and are opened by small toes, which project from a revolving vertical sleeve, which is hollow, and contains a spiral and pinion. The rise and fall of the spiral and pinion are produced by, and instantly correspond to, the rise and fall of the governor balls, thereby increasing and decreasing the projection of the toes which effects the entire variation of cut-off. The governor revolves at precisely the same speed as the engine, and the valves by the above means being directly operated by the governor, the slighest variation of the load on the engine instantly produces a corresponding effect upon the admission of steam. The exhaust valves are directly under the cylinder, and entirely independent of the steam valves, and from their position relieve the cylinder of water, should there be any, at once. He stated in relation to the economy of fuel, that this engine consumed only two pounds of coal per horse power.

Mr. E. B. Bigelow spoke of the importance of the variable cut-off, which may be said to be essential to the economical working of steam expansively. He requested a statement from Mr. McMurtrie, of the difference between the Corliss engine and the one exhibited, to which it was replied that the principle of the cut-off was the same in both, but that the eccentric and its appendages, used in the Corliss to regulate the cut-off, was dispensed with in the Wright engine by a system claimed to be much simpler, cheaper, and less liable to derangement.

FIELD'S TEA FLOAT.

IN the Patent Office list of inventions we often meet with ludicrous attempts to improve upon our ordinary domestic processes. We have, however, lately had an invention submitted to us, by Messrs. Field, of Grey-street, Newcastle-upon-Tyne, which commends itself alike to reason and common sense. It is an improved method of making tea, the apparatus for which purpose consists of a cylindrical sieve which is surmounted by an air-tight chamber which forms the lid, and causes the whole to float when placed in water. The tea is put in the sieve and placed in the tea pot, the required quantity of water being added. The result of practical trials is a saving of 25 per cent. of the tea used, a fact which will be duly appreciated by thrifty housewives. The *rationale* of this useful invention is as follows:—The hottest particles in a body of water are always those which are uppermost. Now we know that to boil the tea itself is to utterly spoil it, as the active principle (theine) becomes dissipated, much of the virtue of the beverage is lost, and it becomes unpalatable. On the other hand, the successful brewing of tea depends upon the herb being exposed for a sufficient time in water of a temperature as near the boiling point as possible. This then is done in Mr. Field's simple contrivance, and the result is the thorough extraction of the theine and a good cup of tea with a saving of about 25 per cent. in consumption.

VENOM OF TOADS.

THE toad, formerly considered as a creature to b feared, does in reality possess a venom capable of killing certain animals and injuring man. The "British Medical Journal" says that this poison is not, as is generally thought, secreted by the mouth; it is a sort of epidermic cutaneous secretion, which acts powerfully if the skin be abraded at the time of contact. Dogs which bite toads soon give voice to howls of pain. On examination it is found that the palate and tongue are swollen, and a viscous mucus is exuded. Smaller animals coming under the influence of the venom undergo true narcotic poisoning, soon followed by convulsions and death. Experiments made by MM. Gratiolet, Cloez, and Vulpian, show that the matter exuding from the parotid region of the toad becomes poisonous when introduced into the tissues. A tortoise of the species "Testudo Mauritanicae" lamed in the hind foot, was completely paralysed at the end of fifteen days; and the paralysis lasted during several months. Some savages in South America use the acid fluid of the cutaneous glands of the toad instead of the curara. The venom exists in somewhat large quantity on the toad's back. Treated with ether, it dissolves, leaving a residuum the evaporated solution exhibits oleaginous granules. The residuum contains a toxic power sufficiently strong, even after complete desiccation, to kill a small bird.

LAMP CHIMNEYS.

EVERY person who has had any experience with lamp chimneys is aware of the seemingly singular want of uniformity in the length of time they will stand use. Some will last for months, while others, apparently as sound and good, will break after a short use, without any apparent cause. The great cause of their being brittle and breaking so easily lies in the material they are made from. There is "shoddy" in glass as well as in cloth. Cheapness being the order of the day, a great many manufacturers make chimneys from silicate of lime instead of silicate of lead. The glass made from the silicate of lime has about the following proportions:—Sand, 100; soda, 45; lime, 20 to 25; nitre, 7 to 10. Lime being a non-conductor of heat, the chimney will not bear the expansion caused by the heat; and, if by gradual heating, the chimney does not break on the lamp, a few times heating makes it so brittle that it breaks with the least effort at cleaning it, no matter how much care is used. The silicate of lead has about the following proportions:—Sand, 100; lead, 40 to 50; soda, 20 to 25; nitre, 10 to 15. Lead being very ductile and a good conductor of heat, a chimney made from this formula will almost melt before it will crack with the heat. The uninitiated may tell the difference of the chimneys made of these different qualities of glass by ringing them; the vibration from the lead-glass chimney has a sweet, bell-like sound, whilst the lime-glass has a short harsh sound. The difference of the cost of manufacture is only, in material, about 8d. per dozen. Another point

Digitized by Google

is in annealing; chimneys, as a general rule, are not annealed. Under a powerful microscope the difference can be seen in the glass; the particles in the annealed glass lie close and compact, while the unannealed seem ready to diverge.—"American Inventor."

Correspondence.

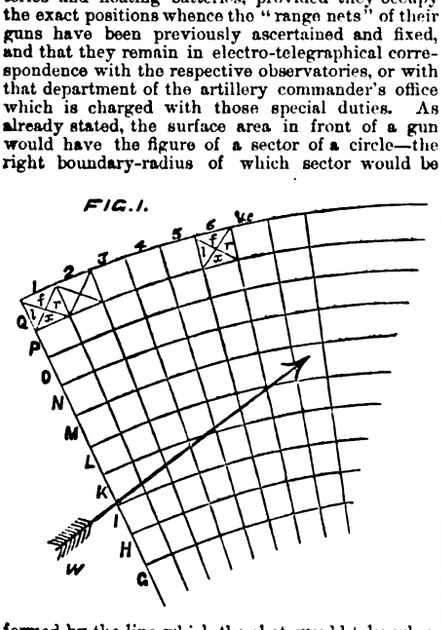
SUGGESTIONS ON THE DEFENCE OF FORTRESSES.

No. VI.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—In a former letter I alluded to the matter-of-course necessity of there being in the possession of the defenders very correct topographical plans or models of the surface configuration of the land and surface and bottom of the sea surrounding a fortress or fortified harbour. I also alluded to such artificial modifications of the surface of the ground as would tend to deprive the enemy of any possible shelter against our fire; and, as regards the latter suggestion, I wish it to be understood that a short-sighted economy should not be allowed to cause the defenders to shrink from carrying out such changes on a very large scale wherever, on consideration of the great improvements in the means of attack, such should be necessary, in order to insure an undoubted superiority in the defence. For the sake of greater brevity and clearness in the following suggestions, let us suppose the surrounding ground to be a level plain. It should also be borne in mind, that under the observatories to which I shall occasionally have to allude, I do not mean only those observatories which may be placed on the high armour-plated watch-towers, but also other observatories which it may be deemed expedient to erect here and there throughout the works at a less height. For instance, at a certain carefully-measured distance from each other on each side of an important battery, and situated on a level with the same, we may have such observatories for measuring distances and guiding the fire of the guns—the object fired at being visible from each observatory, though invisible to the gunners of the battery. The reasons why such observatories should be sufficiently distant from the batteries in action and from the aerial and terrestrial oscillations, and the smoke and turmoil, caused by the discharges of very heavy guns, are obvious. Besides, now, the generally-practised subdivision of a general plan into various large scale sections, in order to be thus able to express clearer the minute detail-features, I should suggest another subdivision of the area of ground in front of the various works into as many sectors of circles as there are guns whose fire we wish to guide by means of our observatories. To avoid complication, let us suppose only our big stationary guns to be included in that arrangement—although it will easily be seen that the arrangement could be applied to all our guns, including also our movable artillery, and even our locomotive batteries and floating batteries, provided they occupy the exact positions whence the "range nets" of their guns have been previously ascertained and fixed, and that they remain in electro-telegraphical correspondence with the respective observatories, or with that department of the artillery commander's office which is charged with those special duties. As already stated, the surface area in front of a gun would have the figure of a sector of a circle—the right boundary-radius of which sector would be

FIG. 1.



formed by the line which the shot would take when the gun is trained to its rightmost bearing, the left boundary-radius by the left fire-line of said gun—while the front arc is formed by the longest range the gun could reach, or by any shorter range the judgment of the defenders may fix upon as the front boundary of such a sector or "range net." Fig. 1 shows a portion of such a range net, and it will be seen that the area of it is subdivided by a number of arcs and radii intersecting each other at (say) equal distances, the distances between the arcs being lettered, and the distances between the radii being numbered, so that any single one of the quadrangles or targets composing such a range net could be easily and distinctly indicated by a letter and a figure (like the squares are marked on a chess-board.) Then each individual target of the range net may again be subdivided by drawing diagonals, joining its four angles (*vide* diagram fig. 1, Q 1, Q 6, &c.), thus creating four triangles, respectively marked

f—front
l—left
r—right
x—rear

So that, for example, the telegram Q 1 *f.* received from the observatory, would sufficiently and clearly indicate to the gunners that they would have to give to their guns such a horizontal and vertical angle as to hit that particular triangle. But, further, each such triangle may again be subdivided into four triangles, by simply drawing straight lines from centre to centre of the sides forming the larger triangle (this subdivision is not shown in the diagram) and each individual one of these subdivisions (if not specially marked) could also easily be indicated in the telegram, in target Q 1—

Q 1 *f. c. t.* . . .	Q 1 front,	centre	triangle.
„ *l. t.* . . .	„	left	„
„ *r. t.* . . .	„	right	„
„ *x. t.* . . .	„	rear	„

or

Q 1 *l. f. t.* . . .	Q 1	left front	triangle.
„ *l. t.* . . .	„	left	„
„ *c. t.* . . .	„	centre	„
„ *x. t.* . . .	„	rear	„
